RE: Enumclaw Closed Landfill 2020 Annual Groundwater Data Evaluation Report

The purpose of this memorandum is to transmit a copy of the *Enumclaw Closed Landfill 2020 Annual Groundwater Data Evaluation Report*. This report is for the 2020 hydrogeological year (October 1, 2019 through September 30, 2020). This report includes an executive summary, site specific summary, exceedances table, trend test table, recommendations, potentiometric surface maps (p-maps), time-concentration plots of parameters of interest, and field and lab data in PDF format. The groundwater quality discussion is focused on exceedances, trend table, graphs, and p-maps.

We will continue to provide these reports on groundwater data evaluation as part of the reporting requirements. We will address any revisions and concerns that you might have about this document in our next annual report. We appreciate your comments to improve these reports.

If you have any questions regarding this report, please call Laura Belt at 206-477-5215 or me at 206-263-6921.

Enumclaw Closed Landfill 2020 Annual Groundwater Data Evaluation Report Certification

I certify in accordance with the requirements of Chapter 18.220 RCW, that the contents of this Groundwater Data Evaluation Report were prepared under my direction under a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Where applicable, some specific and related hydrogeologic portions have been duly certified by the responsible geologist or engineering geologists in accordance with Chapter 18.220.010 (12) RCW. Based on my inquiry of the person(s) directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete.

Executive Summary

This report presents the Enumclaw Closed Landfill (ENLF) evaluation of groundwater quality from September 1986 through September 2020.

ENLF has been closed and capped since 1993. The engineered cap consists of a clay liner, a geomembrane layer, geotextiles, and a vegetated cover. An active gas collection system was installed during operation and closure.

The aquifer underlying the ENLF is a single unconfined aquifer. There are currently five down or side gradient wells, and one upgradient well monitoring the groundwater surrounding the ENLF. Historically, the groundwater flow direction has been to the west. The most recent potentiometric maps agree with past flow directions.

Monitoring well MW-3 was installed to be the background monitoring well, upgradient of the landfill.

Side gradient monitoring well MW-6A is characterized by low concentrations of landfill gas and leachate indicator parameters which fall within a narrow range. This well is not considered affected by the landfill.

Impacts from past landfilling practices caused some water quality exceedances, mainly at side gradient monitoring well MW-1 and downgradient monitoring well MW-2. Since the 1993 Phase II closure, overall water quality has improved significantly. Impacts to the aquifer from the landfill have decreased after closure and attenuated through naturally occurring processes to low levels. Both of the historically impacted monitoring wells, MW-1 and MW-2, have improved water quality with decreasing or stable trends for the past decade, particularly in monitoring well MW-2. Multiple detections are listed in Table 2-3. Monitoring well MW-1 detected vinyl chloride once in the 2020 hydrological year.

Monitoring wells MW-4, MW-5D, and MW-8 were decommissioned and replaced by monitoring wells MW-9 and MW-10 in late 1999, both downgradient wells. Monitoring well MW-9 has shown low and stable conditions in several indicator parameters. Monitoring well MW-10 has had some elevated levels of indicator parameters; however, these parameters remain below regulatory standards and in general exhibit stability.

For the side gradient and downgradient wells, the time-concentration plots, exceedance tables, and trend tables show the improvements in water quality between the historical samples (samples before the most recent eight samples as the “long-term”) and recent samples (most recent eight samples as “short-term”). Recent samples show lower concentrations, narrower ranges, fewer detections of volatile organic compounds (VOCs), and fewer exceedances of water quality standards.

In 2017, the *Post-Closure Maintenance and Evaluation Report in Preparation for Termination of Post-Closure* for ENLF determined the next steps in moving towards ending the post-closure maintenance period. This includes reduction in sampling parameters and frequency, continued monitoring of cover for stabilization, and continued landfill gas (LFG) monitoring. Also, in 2017, the King County Solid Waste Division commissioned a new LFG flare designed to manage decreasing

flow of LFG until Enumclaw Landfill can go to a passive LFG system. In July 2018, the *Post-Closure Maintenance Evaluation Report Cover Settlement Addendum* determined that ENLF meets the settlement criteria for termination of post-closure care as defined in the Washington State Department of Ecology post-closure termination guidance document (Publication No. 11-07-006). On September 2, 2020 Public Health – Seattle & King County approved a variance to continue semi-annual groundwater monitoring and to limit VOC analysis to just vinyl chloride for all wells. Groundwater at ENLF will only be sampled during second (April 1st – June 30th) and fourth (October 1st – December 31st) quarters. In April of 2019, approval was received from the Puget Sound Clean Air Agency to stop flaring landfill gas, and in December of 2019, a rebound test began to determine the effectiveness of passive landfill gas biofiltration. The rebound test was concluded in November of 2020, and an evaluation of the results will be prepared during first quarter 2020.

1 INTRODUCTION

1.1 Objectives

The objectives of the ENLF groundwater quality evaluation are:

- Assemble groundwater quality data from September 1986 through September 2020.
- Review data and perform statistical analyses to evaluate any water quality trends and to compare water quality between monitoring wells.
- Compare water quality data with water quality standards in effect at the time of sampling and document exceedances of water quality standards for hydrological year 2020.
- Determine whether impacts to groundwater quality recorded in monitoring wells can be attributed to the landfill.

1.2 Landfill Summary

The Enumclaw Closed Landfill (ENLF) is located approximately 1.5 miles east of the City of Enumclaw, King County, Washington (Figure 1-1). The property encompasses approximately 39 acres, is owned by the City of Enumclaw, and is leased by King County Solid Waste Division (KCSWD) as the landfill operator. Landfilling operations at the property began in the early 1950s under the informal supervision of the City of Enumclaw and Public Health – Seattle & King County (PH-SKC). ENLF is subject to Chapter 173-304 WAC because of its April 1993 closure date.

This report includes groundwater quality and water level data from September 1986 to September 2020. Between June 1986 and February 1988, groundwater sampling was performed by Sweet-Edwards/EMCON. KCSWD took over quarterly sampling in February 1988 and monitoring activities continue through to the present.

Groundwater sampling was performed at four on-site monitoring wells (MW-1, MW-2, MW-3, and MW-6/6A), three off-site monitoring wells (MW-4, MW-5D, and MW-8), and at one off-site domestic well (MW-EOS) until 1999 (Table 1-1). In 1999, three wells were decommissioned (MW-4, MW-5D, and MW-8) and two new wells were installed (MW-9 and MW-10). Since then, groundwater sampling is performed at six on-site monitoring wells. Figure 1-2 Landfill Features shows monitoring well locations.

There are currently twelve landfill gas (LFG) probes which are monitored for compliance on the landfill property and an additional 21 LFG extraction wells located throughout the covered refuse area. LFG extraction wells are monitored weekly and compliance probes are read by KCSWD operations staff on a quarterly basis.

1.2.1 Previous Investigations and Landfill Improvements

Between 1983 and 1988, three hydrogeologic investigations were performed at the ENLF.

In August 1983, initial investigations included the installation of three monitoring wells (MW-1, MW-2, and MW-3). The three wells ranged in depth from 65 feet to 110 feet below ground surface (bgs). Results of the investigation are included in the 1984 “Groundwater Geology/Quality Investigations for the Rural Landfills”.

In 1986 and 1987, R. W. Beck and Sweet Edwards & Associates performed an expanded landfill characterization that included the installation of five additional monitoring wells (MW-4, MW-5D, MW-6, MW-7, and MW-8). A beneficial use survey indicated that most residences in the area utilize a public water supply system.

Phase I closure of the landfill (placement of final cover over the north half of the landfill) began in the late spring of 1988 and was completed in November 1989. The cover cap consists of a 60-mil high density polyethylene (HDPE) geomembrane cap over surface soils, a geotextile, a 1 foot drainage layer, and 1 foot of topsoil. Also constructed during partial closure was a surface water/storm water sedimentation pond located west of MW-7 and north of MW-2.

Monitoring well MW-7 was abandoned in June 1988 due to landfill closure activities that included removal of the former leachate collection pond and construction of the adjacent storm water sedimentation and infiltration basins (EMCON, 1992). We were unable to find any further information on the construction of these basins.

Until the summer of 1989, leachate seeps collected from the north side of the landfill were directed to a holding pond located approximately 150 feet southwest of MW-1. In 1989 the pond was replaced by two new ponds, one in the southeast corner of the landfill, the other centrally located on the western side of the landfill. Leachate was pumped from the ponds, transported to, and disposed at both the Cedar Hills leachate treatment system and the City of Enumclaw Wastewater Treatment facility. The need for leachate collection ceased following construction of the landfill cover.

Some improvement in water quality was indicated since partial closure of the north half of the landfill. KCSWD began internal groundwater data evaluation in 1992.

The landfill has received no waste since April 4, 1993. Phase II closure, the final closure, including placement of final cover was completed during the summer and fall of 1993.

Monitoring well MW-6A replaced monitoring MW-6 in August 1993. Monitoring well MW-8 was decommissioned in September of 1999 and replaced with monitoring well MW-9. Monitoring wells MW-4 and MW-5D were also decommissioned in September of 1999 and replaced with monitoring well MW-10. The first sampling events for MW-9 and MW-10 were in the fourth quarter of 1999.

Two gas probes (GP-13 and GP-14) were also decommissioned in September of 1999. Gas probes GP-19 and GP-20 were installed on the landfill near the western property boundary in October of 1999 to replace the decommissioned probes. The hydrogeological interpretation is presented in the

Enumclaw Landfill Monitoring Well and Gas Probe Decommission/Installation Technical Memorandum, 2000. Subsurface landfill gas data is collected quarterly and if an exceedance of the Lower Explosive Limit (LEL) is monitored then KCSWD will notify the PH-SKC.

1.2.2 Current and Future Investigations and Landfill Improvements

Stemming from investigations that started in 2015, it was determined to install a smaller flare that has the ability to reduce vacuum on the system as LFG continues to degrade. The trailer-mounted spark flare was commissioned in October 2017. After nine months of running the flare, which operated approximately 67 percent of the time, in August 2018 the landfill gas at ENLF was sampled and evaluated against the small quantity emission rates as defined in WAC 173-460-150. All toxic air pollutant's loading rates were below the small quantity emission rates allowing for the emissions to be vented directly to atmosphere while meeting air quality standards. In April of 2019, approval was received from the Puget Sound Clean Air Agency to stop flaring LFG. December of 2019, a biofiltration berm was constructed and all the LFG was routed away from the existing trailer-mounted flare to the biofiltration berm for passive LFG polishing treatment. With the transition from active LFG collection to passive, on December 17, 2020 KCSWD started a 12-month LFG rebound test. The purpose of the Rebound Test was to support transitioning the LFG collection system at ENLF from active to passive collection. The low-flow flare and blower system remained at the landfill during the Rebound Test in the event that active collection was triggered based on monitoring results. The Rebound Test monitoring included collection of data from LFG compliance probes, LFG wellfield points, the biofilter system inlet, and within the biofilter. The LFG data (both compliance probes and biofiltration berm emissions monitoring data) collected during the rebound test can be viewed at Appendix F. Groundwater data was also collected from select monitoring wells, MW-1, MW-2, and MW-9. Rebound test data collected for groundwater monitoring under hydrological year 2020 (4th quarter 2019 through 3rd quarter 2020) can be viewed at Appendix E.

KCSWD reviewed the landfill conditions and all pertinent data to determine what is needed for the ENLF to terminate Post-Closure. In 2017, the *Post-Closure Maintenance and Evaluation Report in Preparation for Termination of Post-Closure* for ENLF was completed. The findings in this report stated that regarding groundwater, the ENLF post-closure maintenance period could not be terminated due to a few existing exceedances. However sufficient evidence was presented to support a reduction of monitoring frequency and analyte list in 2018 and 2020. On August 8, 2018 PH-SKC approved a two-year variance to change the groundwater frequency and sampling parameters, On August 6, 2020, KCSWD reapplied for the variance with the request for additional analyte reduction, and on September 2, 2020 PH-SKC approved a variance. The frequency and sampling parameters are as follows:

- Frequency of monitoring was reduced from quarterly to - (spring and fall).
- Volatile Organic Compound (VOC) analytes were reduced to vinyl chloride only. Parameters retained for analysis are:

FIELD PARAMETERS

- Dissolved Oxygen
- pH
- Temperature
- Oxidation-Reduction Potential
- Specific Conductance

CONVENTIONALS

- Total Dissolved Solids
- Total Suspended Solids
- Chloride
- Sulfate
- Alkalinity
- Nitrate
- Ammonia
- Total Organic Carbon

METALS

- Arsenic
- Calcium
- Iron
- Magnesium
- Manganese
- Potassium
- Sodium

VOLATILE ORGANIC COMPOUNDS

- Vinyl Chloride

In July 2018, the *Post-Closure Maintenance Evaluation Report Cover Settlement Addendum* concluded that following cover settlement criteria has been attained for termination of post-closure care as defined in the Washington State Department of Ecology (Ecology) post-closure termination guidance document (Publication No. 11-07-006) at ENLF:

- Slopes are uniform and do not exceed minimum or maximum criteria.
- Routine site inspections performed by KCSWD show no evidence of differential settlement.
- Generally, uniform settlement is less than 0.5 inches of settlement over a 2-year monitoring period. Sufficient data points to prepare settlement trend curves are not available.

With the absence of a leachate collection infrastructure, leachate indicator parameters are analyzed to infer presence of leachate in the groundwater. These indicator parameters, associated with landfill activities, have been observed to be stable or expressed decreasing trends. Groundwater analyses will continue to be monitored for stability and trends, as well as LFG, for another four sampling events through 2022 prior to reevaluation for appropriate sampling frequency.

1.2.3 Geology and Hydrogeology

ENLF landfill characterization was documented in previous reports listed in Section 4, References. This section presents a brief description of the findings of those reports.

The ENLF is situated on the Enumclaw Plateau. The regional geology of the plateau has been described as unconsolidated glacial sediments overlying volcanic bedrock. Figures 1-4, 1-5, 1-6, 1-7,

and 1-8 are geologic cross sections of lines A to A', B to B', C to C', D to D', and E to E' that transect the landfill (shown on Figure 1-3).

Fill / Refuse. Material inferred to be fill was encountered at GP-19, GP-20 and MW-9, ranging in thickness from 7 to 17 feet. The fill encountered in these locations consists primarily of sandy gravel and cobbles, with a minor constituent of silt. Refuse consisting of glass, metal, plastic, wood, paper, and cloth was observed at MW-10.

Oceola Mudflow Deposits. The thickness of the Oceola Mudflow varies greatly because of the method of deposition. It was found to be generally four to eight feet thick south of the landfill, but eroded channels were filled to a depth of approximately 25 feet. North of the landfill, at MW-9/GP-19, the thickness encountered was 19 feet. The Oceola Mudflow has largely been removed from the landfill due to landfill operations. Grain-size analyses for samples collected from MW-9 and MW-10 indicate gravel content between 46.0 and 72.5 percent, with sand comprising the majority of the minor constituent.

Recessional Outwash. The outwash consists primarily of well-graded sand and gravel, with a trace to some silt as interbeds. The outwash deposit encountered at MW-9 is primarily fine to medium sand, with occasional, interbedded organic material. Similar deposits were reported for MW-2, MW-7, and MW-8, generally on the northwestern portion of the study area. A gravel zone approximately 20 feet thick was encountered at MW-10, underlain by sand similar to that observed at MW-9. Gravel deposits in the outwash were also encountered at GP-20 and were previously encountered at MW-4. There is a relatively higher gravel content encountered in a southerly direction. The sand proportion in MW-9, MW-10, and GP-20 ranges from 86.3 to 95.0 percent. The proportion of gravel reported for GP-20 (from the gravel zone) is 92.1 percent. The glacial outwash forms the main water-bearing unit beneath the landfill.

Aquitard. A low-permeability aquitard appears to be present beneath the recessional outwash material; however, it is not likely that this unit is laterally continuous or present at a constant thickness or elevation. Material described as clayey sand, clayey gravel and silty clay were noted on boring logs for monitoring wells MW-4 and MW-7 at elevations ranging from about 700 feet to 720 feet. This low-permeability unit was not encountered during the 1999 well installations.

Tertiary Volcanic Rocks. Bedrock in the immediate landfill area consists of Tertiary volcanic rocks, mostly andesitic in composition. This rock forms a prominent knob adjacent to the northwest part of the landfill and outcrops a few feet north of the fence line. The overburden/bedrock contact is inferred to extend under the landfill; however, the total bedrock thickness and form of the glacial outwash/bedrock contact are not known.

Groundwater investigations were performed to characterize aquifer conditions and water quality in the uppermost aquifer beneath the landfill. Saturated conditions were found in the recessional outwash deposits at depths ranging between 45 and 85 feet bgs, at an approximate elevation of 750 feet above mean sea level (amsl). The seasonal high-water table was found approximately 25 feet below the recorded base of the solid waste. The Recessional Outwash Aquifer is an unconfined aquifer.

Recharge to the aquifer is by direct infiltration around the landfill, and in the uplands to the east of the landfill. The aquifer probably discharges to Newaukum Creek (approximate elevation 680 feet amsl), located approximately two miles west/northwest of the landfill.

A local area of perched water was encountered during drilling of the gas probes on the north property boundary (GP-6, and GP-7). The perched water bodies occur within low permeability portions of a silty sand unit, probably the Ocoala Mudflow. The perched water was at least 30 feet above the Recessional Outwash Aquifer water table. Field measurements of specific conductance and pH were not elevated above normal levels.

Table 1-1
Groundwater Monitoring Wells

Enumclaw Closed Landfill

Monitoring Well	Installation Date	Decommissioned Date	Location Relative to Groundwater Flow	Sampling History	Current Sampling Frequency
MW-1	08/24/83	--	Side gradient	Quarterly since 1987	Biannual ¹

2 DATA EVALUATION

2.1 Groundwater Elevations and Flow Direction

Groundwater levels in individual wells have been plotted as a function of time. Groundwater flow directions were estimated based on water elevations in monitoring wells screened in similar water-bearing zones (Appendix B). Upgradient and downgradient wells are determined by flow direction.

During the 2020 hydrological year, the hydrograph (Figure 2-1) shows seasonal water table fluctuations from around six and a half feet to seven feet for monitoring wells MW-2, MW-9, and MW-10; close to nine feet in MW-6A, about ten and a half feet for monitoring well MW-3 and about eleven feet for monitoring well MW-1. The potentiometric surface of the Recessional Outwash Aquifer for October 2019 and June 2020 are presented in Appendix B. These sampling periods were selected, because historically they represent the lowest and highest static groundwater levels for the hydrological year. The hydraulic gradient for the landfill vicinity ranged from 0.007 to 0.013 (feet/foot) during the Spring 2020 and Fall 2019 monitoring events, respectively. Water level data collected from the six landfill monitoring wells indicated that groundwater flows in a westerly direction. Based on the reported average hydraulic conductivity (280 feet/day) and a porosity of 36 percent, groundwater velocities were estimated to be six to seven feet/day (Appendix B). Groundwater elevations are within historical ranges.

2.2 Data Evaluation Methods

KCSWD assembled the analyte list from parameters listed in WAC 173-200 Water Quality Standards for Groundwaters of the State of Washington, WAC 173-351-990 Appendices I and II, and 40 CFR 141 and 143, National Primary and Secondary Drinking Water Regulations (Appendix A). Field pH, field specific conductance, chloride, sulfate, inorganic nitrogen, dissolved iron, dissolved manganese, and VOCs are useful in characterizing groundwater quality, as indicators of impacts to groundwater from landfill gas and leachate, or in screening for potentially harmful effects to human health and the environment. It is these analytes that the data evaluation focuses on.

Environmental samples are collected, analyzed, and evaluated by the procedures described in the Environmental Monitoring Quality Assurance Project Plan and Sampling Analysis Plan for Cedar Falls, Enumclaw, and Hobart Closed Landfills (QAPP/SAP). The QAPP/SAP describes activities undertaken to ensure analytical results meet data quality objectives and that they are representative of actual groundwater conditions.

The data evaluation used to characterize the groundwater quality for Cedar Falls, Enumclaw, and Hobart Closed Landfills is guided by the QAPP/SAP. Statistical and graphical methods are used to evaluate the data. Descriptive statistics (Appendix C), trend testing (Mann-Kendall test; Appendix C) and time-concentration plots (Appendix D) evaluate the following parameter and analytes; pH (field), specific conductivity (field), alkalinity, ammonia, chloride, nitrate, sulfate, total dissolved solids, dissolved arsenic, dissolved calcium, dissolved iron, dissolved manganese, dissolved potassium, dissolved sodium, and vinyl chloride. In addition to this list there are also time-concentration plots for total organic carbon and descriptive statistics and time-concentration

plots for dissolved magnesium. Constituents cis-1,2-dichloroethene and 1,1-dichloroethane are no longer analyzed for and as a result are no longer included in the descriptive statistics and the time concentration plots. Descriptive statistics and trend testing are divided into long-term samples (previous samples to the most recent eight samples) and short-term (most recent eight samples). These are the parameters and analytes that have either exceeded regulatory limits, have a visual trend for all active wells, and/or parameters that occur with adequate frequency and are relevant for the evaluation of all active wells. The water quality discussion is principally based on exceedances (Tables 2-1), trend tables (Appendix C), graphs (Appendix D), and potentiometric maps (Appendix B). The 2019 hydrological year exceedance table is included as a reference (Table 2-2). Per the letter Update on Closed Landfill Regulatory Reporting Schedule, January 28, 2010, only exceedances that are statistically significant increases over previous samples will be reported to Ecology and PH-SKC.

Data from hydraulically upgradient wells are described first to assist comparison of data between wells and emphasis is on the most recent data. Descriptions of analytical results in the following discussions refer to results obtained during the last eight monitoring events (generally the past two years of quarterly monitoring) unless otherwise noted. Groundwater monitoring data are tabulated in Appendix E. Also, landfill gas monitoring data are tabulated in Appendix F.

2.3 Groundwater Chemistry Results

In 2017, the Method Detection Limit (MDL) was replaced with the Lower Limit of Quantitation (LLOQ) as the laboratory method for determining the lowest quantitative value reported. The LLOQ relies on multiple tests of known standards to produce a calibration curve (linear) in which these curve points are used to determine analytical results with reasonable confidence. Limitations to the LLOQ are due to factors of instrument sensitivity and method analytical uncertainty.

The transition to the LLOQ has varied sample quantitation limits resulting in higher, lower, and unchanged reporting limits. As a result, previously undetected trace metals and volatiles such as vinyl chloride are now quantifiable due to the revised reporting limits.

The Solid Waste Program Variance was approved in September of 2020. This variance renewed the 2018 variance, which reduced the analyte list and frequency of sampling (quarterly to semi-annually) for all groundwater wells, and further reduced the VOC analyte list to only vinyl chloride.

2.3.1 Upgradient Water Quality

Monitoring well MW-3 is located within the landfill property boundary near the southeast corner of the landfill (Figure 1-2) and is screened at elevations between 740.5 feet and 755.5 feet (NAVD 88, below top of PVC). The well was installed as the background, or hydraulically upgradient, monitoring well. Water quality data from 1986 through September 2020 is presented in this evaluation report.

During the 2020 hydrological year, there were two exceedances of the regulatory limit for arsenic in samples from monitoring well MW-3, with a maximum observance at 0.000184 mg/L (Table 2-1). Specific conductance remains low with no statistically significant trend in the recent samples.

Concentrations of chloride remained low and stable with no statistically significant trends. Sulfate and ammonia concentrations have remained low and are showing statistically significant decreasing long-term trends. Nitrate was consistently detected in samples from monitoring well MW-3 at low concentrations and has a long-term increasing trend. As a result of the lower detection limit, dissolved arsenic has been detected in seven of the last eight samples. There have been no dissolved iron detections in the most recent eight samples and there is a long-term decreasing trend. Remaining indicator parameters were undetected in recent samples or displayed low levels and no statistically significant trends (Appendix C).

There were no VOCs detected between October 2019 and September 2020 in monitoring well MW-3 (Table 2-3).

2.3.2 Side Gradient Water Quality

Monitoring wells MW-1 and MW-6A make up the side gradient and monitoring wells MW-2, MW-9, and MW-10 make up downgradient monitoring network at the ENLF.

2.3.2.1 *MW-6A*

Monitoring well MW-6A is positioned within the property boundary of the landfill and south of the solid waste (Figure 1-2) and is screened at elevations between 730.21 feet and 740.21 feet (NAVD 88, below top of PVC). The well is located hydraulically side gradient to the landfill. Water quality in monitoring well MW-6A is very similar to conditions present in monitoring well MW-3.

The pH in recent samples from monitoring well MW-6A has been slightly acidic to neutral with one lower limit exceedance at 6.48. There were two exceedances for arsenic with a maximum concentration of 0.000162 mg/L (Tables 2-1). Field pH, field specific conductance, total dissolved solids, dissolved metals: arsenic, manganese, potassium, and sodium, and nitrate levels were low and stable for both long and short-term. Alkalinity, ammonia, chloride, sulfate, dissolved calcium, and dissolved iron have long-term decreasing trends. No other statistically significant trends were observed during this evaluation period (Appendix C).

There were no VOCs detected between October 2019 and September 2020 in monitoring well MW-6A (Table 2-3).

2.3.2.2 *MW-1*

Monitoring well MW-1 is located within the northern property boundary of the landfill, hydraulically side gradient, and approximately 30 feet from solid waste. Monitoring well MW-1 is screened at elevations between 736 feet and 746 (NAVD 88, below top of PVC). This well was installed in 1983.

The groundwater samples in monitoring well MW-1 exceeded the regulatory standard for arsenic two times with a maximum concentration of 0.0132 mg/L. Monitoring well MW-1 exceeded manganese two times with maximum values of 0.743 mg/L (Table 2-1).

Historically, monitoring wells MW-1 showed impacts to groundwater quality. In the past, samples from MW-1 had high levels of specific conductance, chloride, iron, manganese, and arsenic. However, since the final cover was placed in 1993, most of these parameters have shown long-term decreasing trends or stability. KCSWD analyzes 15 analytes for statistical trends. Of these analytes, samples from monitoring wells MW-1 have shown long-term decreasing trends for seven analytes (Appendix C). The water quality remains at improved conditions. Samples from monitoring wells MW-1 had statistically significant increasing long-term trends for nitrate. Total dissolved solids and sodium levels continue to be low and stable. Ammonia and dissolved manganese in samples from monitoring wells MW-1 are slightly higher than in other wells, but showed long-term decreasing trends.

Vinyl chloride was detected once in monitoring well MW-1 during the 2020 hydrological year with a value of 0.0367 µg/L with a lab qualifier “D” which means sample re-analysis due to dilution. Monitoring well MW-2 had a dichlorodifluoromethane detection in October 2019 with a value of 0.141 with “JT” qualifier (Table 2-3), meaning an analyte concentration reported as present but unquantifiable.

2.3.3 Downgradient Water Quality

2.3.3.1 *MW-9 & MW-10*

Monitoring well MW-9 is located approximately 20 feet inside the fence line and monitoring well MW-10 approximately 45 feet inside the fence line (Figure 1-2). These wells are located hydraulically downgradient of the landfill. Monitoring well MW-9 is screened at elevations between 738.08 feet and 748.08 feet and monitoring well MW-10 between 736.25 feet and 746.25 feet (NAVD 88, below top of PVC). Both wells were installed in the fourth quarter of 1999. Monitoring well MW-10 is installed through 28 feet of refuse.

Measured samples from monitoring wells MW-9 and MW-10 have had slightly acidic pH (field). Samples from monitoring well MW-9 had one exceedance of the lower limit of the pH (field) standard with a value of 5.95 (Table 2-1). There was one exceedance of the lower limit of the pH (field) standard in samples from monitoring well MW-10 with a value of 6.22. Neither samples from monitoring well MW-9 nor samples from monitoring well MW-10 have had any short-term statistically significant trends in 2020. Ammonia, dissolved calcium, dissolved iron, dissolved manganese, and dissolved potassium for samples from monitoring well MW-9 have long-term decreasing trends. Compared to other wells, samples from monitoring wells MW-10 have had relatively higher levels of some indicator and metal parameters but still below regulatory limits. KCSWD has surveyed the area surrounding monitoring well MW-10 to determine if there are potential mechanisms that could result in the detections. There is no detailed information available on the rural activities at adjacent downgradient and side gradient properties that would conclude an immediate concern. It is likely that this well’s placement through refuse is the cause of these intermittent detections. Samples from monitoring well MW-10 have shown a long-term decreasing trend of ammonia, chloride, nitrate, and dissolved iron.

There were no VOCs that were detected between October 2019 and September 2020 in samples from monitoring well MW-9. Acetone, a VOC, was detected in 2020 in MW-10. The sample results were

qualified ‘BJT’, meaning results are only reported as qualitative, i.e. ‘present but unquantified’ and acetone was detected in a method blank (Table 2-3). Acetone is a known lab contaminant.

2.3.3.2 *MW-2*

Monitoring well MW-2 is located within the western property boundary of the landfill; hydraulically downgradient and approximately 320 feet from the toe of solid waste. Monitoring well MW-2 between 737.89 feet and 747.89 feet (NAVD 88, below top of PVC). This well was installed in 1983.

The groundwater samples in monitoring wells MW-2 were slightly acidic. There was one exceedances of the lower limit of the pH (field) standard at monitoring well MW-2 with a value of 5.74. There are long-term trends for decreasing pH and specific conductivity measured in samples from monitoring well MW-2. Monitoring well MW-2 exceeded the regulatory standard for arsenic two times with a maximum value of 0.000119 mg/L.

Historically, monitoring well MW-2 showed impacts to groundwater quality. In the past, samples from MW-2 had high levels of specific conductance, chloride, iron, manganese, and arsenic. However, since the final cover was placed in 1993, most of these parameters have shown long-term decreasing trends or stability. KCSWD analyzes 15 analytes for statistical trends. Of these analytes, samples from monitoring well MW-2 have shown long-term decreasing trends for eight analytes (Appendix C). The water quality remains at improved conditions. Samples from both monitoring wells MW-1 and MW-2 had statistically significant increasing long-term trends for nitrate. Total dissolved solids and sodium levels continue to be low and stable. Ammonia and dissolved manganese in samples from monitoring well MW-2 are slightly higher than in other wells, but both have long-term decreasing trends.

Monitoring well MW-2 had a dichlorodifluoromethane detection in October 2019 with a value of 0.141 with “JT” qualifier (Table 2-3), meaning an analyte concentration reported as present but unquantifiable.

3 SUMMARY AND CONCLUSIONS

This summary and conclusions section present KCSWD's interpretation of the geology and hydrogeology of the landfill, groundwater chemistry, short and long-term statistically significant trends of groundwater quality, natural groundwater chemistry processes, and improvements in water quality due to closure activities.

3.1 Summary

Geology at the ENLF consists of three units, the Ocoala Mudflow Deposits, the Recessional Outwash Deposits, and andesitic bedrock. The Ocoala deposits have largely been removed from the landfill and play no significant role. Andesitic bedrock occurs as a knoll near the northwest corner of the landfill. The recessional outwash consists of greater than 100 feet of moderately loose sand and gravel, with occasional silt horizons.

During the 2020 hydrological year, groundwater elevations were within the recessional outwash deposits between 748 and 768 feet above mean sea level. The shallow water table aquifer is recharged east of the landfill and groundwater flows west, probably discharging at Newaukum Creek. The hydraulic gradient was determined to range between 0.007 and 0.013 feet/foot in the 2020 hydrological year. Based on the reported average hydraulic conductivity (280 feet/day) and a porosity of 36%, groundwater velocities were estimated to be six to seven feet/day in the 2020 hydrological year. Groundwater elevations are within historical ranges.

Twelve groundwater monitoring wells have been installed around the perimeter of the landfill of which six monitoring wells were monitored during 2020 hydrological year. Quarterly monitoring has occurred since September 1986 and from 2018 semi-annual monitoring has been approved by PH-SKC. Monitoring well MW-7 was abandoned in 1988. Monitoring well MW-6 was destroyed during Phase II closure in 1993 and replaced by monitoring well MW-6A. Monitoring well MW-EOS became inoperable in 1993. Monitoring well MW-8 became inaccessible in 1998 and abandoned in fall 1999, being replaced by monitoring well MW-9. Monitoring wells MW-4 and MW-5D were decommissioned in the fall of 1999 and replaced by monitoring well MW-10.

The hydraulically upgradient well was determined to be monitoring well MW-3. The downgradient wells include monitoring wells MW-2, MW-9, and MW-10. The side gradient wells include monitoring wells MW-1 and MW-6A.

3.2 Groundwater Chemistry

Groundwater data were evaluated to determine what effects have occurred from the landfill. The analytes evaluated include indicator parameters and select analytes including, nonmetals, metals, and VOCs.

Data analysis has been performed using trend testing and time-concentration plots to evaluate differences and changes in groundwater chemistry over time. Exceedances and VOC detections were also emphasized.

3.2.1 Upgradient Water Quality

Information presented in the database, trend analyses, and time-concentration plots provides descriptions of background groundwater quality. The parameters of pH (field), specific conductance (field), alkalinity, ammonia, chloride, nitrate, sulfate, total dissolved solids, dissolved iron, and dissolved manganese were used to characterize upgradient water quality because they occur with adequate frequency for meaningful evaluation. Results indicate relative stability and low concentrations for these parameters. Lower detection capabilities in the laboratory now show that there is a presence of arsenic at monitoring well MW-3, indicating that some of the arsenic present in these wells could be contributed to background conditions. Also, the Ecology background study on arsenic, i.e. Puget Sound basin the natural background is 0.008 mg/L. Considering additional evaluation methods, and the magnitude of the variability, it is concluded that monitoring well MW-3 has not been affected by the landfill and that the chemical data represent natural aquifer conditions in the vicinity of the landfill.

3.2.2 Side Gradient Water Quality

Side gradient monitoring well MW-6A, displays water quality conditions similar to the upgradient well: narrow ranges and low concentrations of indicator parameters. Monitoring well MW-6A had the lowest concentrations of most indicator parameters among all wells. Remaining trend test results indicate continued stability or decreasing trends in the parameter concentrations. From analysis of statistically significant trends, time-concentration plots, similar groundwater characteristics to the upgradient monitoring well MW-3, and the infrequency of VOC detections, this well does not show evidence that it has been impacted by the landfill.

Previous reports have documented impacts to water quality attributable to the landfill in side gradient monitoring wells MW-1 (north part of landfill). Monitoring well MW-1 shows improvements with one a smaller number of decreasing long-term trend and only one vinyl chloride detection in 2020 hydrological year. As summarized in Appendix C, monitoring wells MW-1 show statistically decreasing long-term trends in several of the analytes that were assessed.

Monitoring well MW-1 detection of vinyl chloride exceeded the regulatory standard.

It is concluded that closure activities undertaken at the ENLF have contributed to improvements in side water quality.

3.2.3 Downgradient Water Quality

Previous reports have documented impacts to water quality attributable to the landfill in down gradient monitoring well MW-2, MW-9 and MW-10 (west part of landfill). Monitoring well MW-2

water quality has improved considerably and conditions seem to be closer to those in MW-3. Monitoring well MW-2 shows improvements with smaller number of decreasing long-term trend.

Monitoring wells MW-9 and MW-10 were characterized by wider ranges and higher concentrations of indicator parameters than the other wells. The water quality in monitoring well MW-9 has showed considerable improvements and has five long-term decreasing trends. Intermittent detections of indicator constituents in samples from monitoring well MW-10 are likely due to the well's placement in refuse.

Volatile organic compound, dichlorofluoromethane and acetone were detected in samples from monitoring wells MW-2 and MW-10 with qualifier 'JT' (i.e. 'present but unquantified') and 'BJT' (i.e. 'present in blank but unquantified').

3.3 Recommendations/Future Action

Recommendations for the ENLF are:

- Continue monitoring as described below, unless a statistically significant change occurs in the groundwater quality, at which point quarterly sampling will be resumed, in accordance with the QAPP/SAP.
- Continue semiannual groundwater monitoring for all wells.
- Continue VOC analysis for just vinyl chloride for all wells.
- Continue sampling the following parameters:

FIELD PARAMETERS METALS

- Dissolved Oxygen
- pH
- Temperature
- Oxidation-Reduction Potential
- Specific Conductance

METALS

- Arsenic
- Calcium
- Iron
- Magnesium
- Manganese
- Potassium
- Sodium

CONVENTIONALS

- Total Dissolved Solids
- Total Suspended Solids
- Chloride
- Sulfate
- Alkalinity
- Ammonia
- Total Organic Carbon
- Nitrate

VOLATILE ORGANIC COMPOUNDS

- Vinyl Chloride

- KCSWD will review four groundwater sampling events through 2022 prior to reevaluate sampling frequency and to determine what frequency is most representative of conditions surrounding the landfill.
- KCSWD will provide the full set of rebound test data results (December 2019 to December 2020), including both groundwater and landfill gas evaluation data. This data will be included the data evaluation to Ecology and PH-SKC in the form of a memo during the first quarter 2021.

KING COUNTY SOLID WASTE DIVISION
QUALIFIER INFORMATION
(Effective 8/27/2015)

QUAL	QUALIFIER DESCRIPTION
U	Undetected; Analyte Concentration Less than Method Detection Limit (< MDL)
T	Estimated; Less than Reporting Detection Limit (<RDL) but Greater than Method Detection Limit (> MDL)
J	Reported Value is an Estimate
B	Matrix Target Analyte Present in Blank, AND, Sample Result Less than or Equal to 10x Blank Detection
C	Confluent Growth
E	Estimated; Outside Expected Accuracy
H	Exceeds Holding Time
R	Data Rejected
S	Sample Handling Errors
X	Too Numerous to Count
D	Re-analysis Due to Dilution
P	PASS – Qualitative Result Acceptable
F	FAIL – Qualitative Result is not Acceptable
G	Estimated with Low Bias (Coliform; BOD; All Other Chemistry Parameters)
L	Estimated with High Bias (BOD; All Other Chemistry Parameters)

**KING COUNTY SOLID WASTE DIVISION
HISTORICAL QUALIFIER INFORMATION**
(Applicable to samples taken prior to 4/1/2009)

QUAL	QUALIFIER DESCRIPTION
B	Analyte Found In Associated Method Blank
D	Compound Analyzed at a Secondary Dilution Factor.
E	Exceed The Calibration or Linear Range.
J	Estimated Value Less Than Practical Quantitation Limit And Greater Than The Method Detection Limit.
M	Raised Detection Limit. Due to Matrix Interference.
O	Analyzed Beyond Specified Holding Time.
P	Pesticide/PCBs > 25% Difference Between Columns.
R	Rejected Data
U	Analyte Not Detected at Given Value.
CG	Confluent Growth (Bacterial Analyses Only)
ED	Excess Debris on Growth Media (Bacterial Analyses Only).

More than one qualifier can be applied to any analytical result.

Non-numeric result NOTATIONS:

NM – Coliforms ‘Not Measured’ in sample (no CO₂ production).

P – Coliforms ‘Present’ in sample (CO₂ production) but can’t be quantified.

NA Not Analyzed

NT Not Tested

Others:

TNTC - Too Numerous To Count

TECHNICAL MEMORANDUM

November 30, 2020

TO: Subrina Tahsin, Engineer II, Facility Engineering and Science Section, Solid Waste Division, Department of Natural Resources and Parks (DNRP)

FM: Sevin Bilir, Environmental Scientist IV, Science and Technical Support Section, Water and Land Resources Division, DNRP

RE: Potentiometric Groundwater Surface Maps & Groundwater Velocity Calculations
Water Year 2019–2020 Results
Enumclaw Closed Landfill, King County, Washington
Project No. 1033594 – Task 22.14.137.43

The King County Water and Land Resources Division (KCWL RD) submits this memorandum report on groundwater conditions during the 2019–2020 water year for the recessional outwash aquifer beneath the Enumclaw Closed Landfill (Landfill), in accordance with the *Proposal for Potentiometric Groundwater Surface Maps & Groundwater Velocity Calculations, King County Closed Landfills (Cedar Falls, Enumclaw, Hobart, and Vashon Island) and Cedar Hills Regional Landfill* (KCWL RD, 2020).

King County Solid Waste Division (KCSWD) personnel measured depth to water at the landfill semiannually (fall 2019 and spring 2020) during the 2019–2020 water year. As per recommendation by Aspect (2017), frequency of monitoring has been reduced from quarterly to semiannually. Measurements will continue to be taken only during the fall (October through December) and the spring (April through June) which historically reflect the lowest and highest water levels for the water year, respectively (Aspect, 2017).

These measurements were received by KCWL RD on July 1, 2020 and were used to:

1. Evaluate the potentiometric groundwater surface during the fall 2019 and spring 2020 monitoring events;

2. Determine the groundwater flow direction and horizontal gradient for the fall 2019 and spring 2020 monitoring events; and
3. Calculate the groundwater flow velocities for the fall 2019 and spring 2020 monitoring events.

While groundwater elevations in the spring of 2020 were on average eight feet higher than the previous spring, there were no significant changes in the interpreted regional aquifer groundwater flow direction or hydraulic parameters since the report submitted for the 2018–2019 water year.

Groundwater Elevation Data

The KCSWD measured depth to groundwater levels semiannually during the 2019-2020 water year at six monitoring wells completed in the recessional outwash aquifer along the perimeter of the Landfill. Table B-1 lists the well identifications, easting and northing location data, top of casing elevations, measured depth to water levels, and calculated groundwater elevations for the recessional outwash aquifer for wells accessed for depth to water level measurements.

Water levels were on average greater than two and eight feet above those reported during the fall and spring in the 2019–2020 water year monitoring events, respectively, than those reported in the previous 2018-2019 report.

Figures B-1 and B-2 show well locations, groundwater elevations, and inferred groundwater potentiometric surface contours in the recessional outwash aquifer for both fall and spring monitoring events.

Direction of Groundwater Flow

Figures B-1 and B-2 show groundwater potentiometric surface contours and interpreted groundwater flow directions in the recessional outwash aquifer, based on the 2019–2020 water level measurements. Groundwater elevations indicate that groundwater generally flowed west during both monitoring events.

Table B-2 lists the flow direction for each monitoring event based on measurements taken and mapping of groundwater elevation contours.

Groundwater Parameters

Table B-2 presents a summary of the groundwater parameters. Horizontal hydraulic conductivity and effective porosity values were based on the ranges reported in

Enumclaw Landfill Monitoring Well and Gas Probe Decommission/Installation Technical Memorandum (AES, 2000). Horizontal hydraulic conductivity and effective porosity values are 280 feet per day (ft/d) and 36 percent, respectively (AES, 2000).

The hydraulic gradient was determined using the potentiometric surface maps (Figures B-1 and B-2). Average hydraulic gradients were approximately 0.013 and 0.007 ft/ft during the fall 2019 and spring 2020 monitoring events, respectively.

Horizontal groundwater velocity was calculated for the recessional outwash aquifer. Average horizontal groundwater velocities for the aquifer beneath the Landfill, are based on spatial differences in aquifer parameters, hydraulic gradients, and calculations using the following formula:

where:

$$v = \frac{I}{n_{eff}} K \frac{\Delta H}{\Delta L}$$

v = Groundwater velocity [L/t]

n_{eff} = Effective porosity [dimensionless]

K = Hydraulic conductivity [L/t]

$\frac{\Delta H}{\Delta L}$ = Hydraulic gradient [L/L]

The average velocities calculated for groundwater levels during the fall 2019 and spring 2020 monitoring events were approximately seven and six ft/d, respectively. These velocities were both within the range of average groundwater velocities calculated based on groundwater levels measured for the same monitoring events during the 2018–2019 water year.

Notes:

1. Water level measurements made by the KCSWD personnel.
2. Reference datum for eastings and northings is the North American Datum of 1983 (NAD83/11). Easting and northings were resurveyed in April 2019.
3. Elevations are reported in feet (ft) above mean sea level (MSL) based on the North American Vertical Datum of 1988 (NAVD 88). Top of casing elevation were resurveyed in April 2019.
4. Semiannual monitoring events represent seasons that historically reflect lowest (October through December) and highest (April through June) groundwater levels.

NOTES:

Short - eight most recent analyses in the last two years.

Long - historical data up to the last eight samples, but no greater than 50 samples.

D - decreasing trend

I - increasing trend

-- - no detectable trend or too few data point to determine significance

NaN - too few data points to calculate probability

Probability - probability null hypothesis (i.e. 'No Trend') is true (aka p-value)

Significant - trend is significant at 0.05

µmhos/cm - micorSiemens per centimeter

mg/L - milligram per liter

µg/L - microgram per liter

APPENDIX D

Time-Concentration Plots

Parameters

Field pH
Field Specific Conductance
Alkalinity
Ammonia
Chloride
Nitrate
Sulfate
Total Dissolved Solids
Total Organic Carbon
Arsenic
Calcium
Iron
Manganese
Magnesium
Potassium
Sodium
Vinyl Chloride

Abbreviations used in graphs:

<u>Abbreviation</u>	<u>Description</u>
DL	Detection Limit
mg/L	milligrams/ Liter
ug/L	micrograms/ Liter
