**Hobart Closed Landfill
2018 Annual Groundwater Data Evaluation Report Certification**

I certify in accordance with the requirements of Chapter 18.220 RCW, that the contents of this Groundwater Data Evaluation Report were prepared under my direction under a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Where applicable, some specific and related hydrogeologic portions have been duly certified by the responsible geologist or engineering geologists in accordance with Chapter 18.220.010 (12) RCW. Based on my inquiry of the person(s) directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete.

Name: Anne Holmes P.E.	Title: Supervising Engineer, Facility Engineering and Science Unit	Date: 11/13/18

EXECUTIVE SUMMARY

This annual report presents the Hobart Closed Landfill (Landfill) evaluation of groundwater quality and water level data collected from October 1986 through September 2018.

Groundwater investigations in the mid-1980s led to remediation design and installation of a bentonite Slurry Wall to isolate the shallow groundwater beneath the refuse from the aquifer present below the Landfill. The groundwater beneath the site was pumped out and a lower water level inside the Slurry Wall has been maintained since 1989. Final closure of the north half of the Landfill was completed in 1990 and of the south half in 1994, with the placement of a High Density Polyethylene (HDPE) cap, drainage layer, and vegetative layer over the refuse. From final closure until recently, pumping had not been required to maintain water levels below refuse and an inward gradient across the Slurry Wall.

Groundwater quality and water level data are collected quarterly and reviewed to summarize and evaluate groundwater quality at the Landfill and determine changes, if any. Water quality data includes samples collected from nine monitoring wells.

Groundwater flow beneath the Landfill has been evaluated by a licensed hydrogeologist. The report is included as Appendix B. The groundwater beneath the Landfill occurs in two aquifers; the Shallow Aquifer and the Deep Aquifer. In both zones, the water generally flows in a westerly direction.

During the current evaluation period, groundwater in both aquifers has continued improvements in water quality characteristics when compared with pre-Slurry Wall installation groundwater quality. The demonstrated water quality improvements together with the maintained head differential across the Slurry Wall provide indications that the system is continuing to function as designed. Monitoring at the Landfill will continue throughout the required post closure period.

The water levels inside and outside the Slurry Wall are monitored quarterly. This data is used to ensure that the water levels within the Slurry Wall remain below the base of waste, and that the water levels inside are sufficiently below those outside the Slurry Wall so as to maintain an inward hydraulic gradient and minimize the potential for migration of contaminants. Since approximately 2009, seasonal high water levels within the Slurry Wall have successively increased due to higher than historical rates of rainfall, increasing the infiltration through the cover. In 2014, an evaluation of cover integrity at geomembrane penetrations was conducted and repairs made in three locations in early 2015. Continued investigative efforts are underway to evaluate the environmental control systems and methods to mitigate water level rise. A contingency plan to pump and haul water to treatment was activated in 2017. This action helps maintain hydraulic gradients, waste isolation and protection of groundwater quality. An evaluation of the containment system is being performed to determine what improvements can reduce the need for pumping.

PURPOSE

The purpose of this report is to provide an annual update on groundwater quality and water level data collected at the Landfill in accordance with WAC 173-304-405 (4)(d). The focus will be on the data collected during the last year, from October 2017 through September 2018. Historical data will be used as a comparison and to provide context for these results. Based on this analysis, further recommendations will be made as to how to continue to ensure the groundwater quality at the Landfill.

CHAPTER 1: LANDFILL OVERVIEW

1.1. OBJECTIVES

The objectives of this groundwater quality evaluation report for the Landfill are as follows:

- Review groundwater quality data from September 1986 through September 2018.
- Perform statistical analyses to evaluate any water quality trends, and to compare water quality between monitoring wells.
- Compare water quality data with water quality standards in effect at the time of sampling. Document any exceedances of Washington State Groundwater Quality Standards criteria.
- Determine whether any exceedances or trends as described above can be attributed to the Landfill.

1.2. SITE DESCRIPTION

The Landfill is located on 276th Street Southeast, between the towns of Hobart and Ravensdale, about 25 miles southeast of Seattle (Figure 1). The Landfill is owned by King County. It was operated and is maintained by the King County Solid Waste Division (KCSWD). It occupies approximately 75 acres, of which about 35 acres have been used for refuse disposal.

Prior to the early 1950s, the Landfill site was utilized as a sand and gravel pit. Landfilling activities began in the 1950s, with refuse being placed in the former sand and gravel pit. Open burning of refuse occurred until the early 1960s. From the early 1960s to 1990, refuse was placed in a controlled manner, including compaction and later placement of a daily cover.

A site characterization in August 1983 included construction and sampling of four groundwater monitoring wells and characterization of surficial soils. Expanded site characterizations were performed between August 1985 and March 1986 and consisted of additional three wells installed in solid waste, and 22 wells installed in native soils surrounding the Landfill. Quarterly groundwater monitoring is currently performed in nine wells, of which six are in the Shallow Aquifer and three are in the Deep Aquifer (Table 1.1). The Landfill site map (Figure 2) shows the monitoring well locations.

Water quality impacts to the Shallow Aquifer were detected on site, triggering remedial activities in the Shallow Aquifer. Site remediation occurred during 1988 and 1989, including construction of a low permeability soil and bentonite slurry cutoff wall (Slurry Wall) around the Landfill. Site remediation is further described in Section 1.2.2.

In 1990, an HDPE final cover with a gas collection system was installed over 14 acres of the solid waste at the northern half of the Landfill (Phase 1 closure). In 1994, the remaining southern portion of the Landfill was closed under the Phase 2 closure project. This included: construction of a final cover and landfill gas (LFG) collection field over the south half of the Landfill; modifications and

repairs to the existing LFG flare system; and, utilization of existing infiltration basins for stormwater runoff.

1.2.1. GEOLOGY AND HYDROGEOLOGY

The Landfill site characterization, including history, hydrogeology, and details regarding the Slurry Wall, has been documented in the reports listed in the References section. This section presents a summary of these reports findings.

The Landfill is located within the Puget Sound lowlands of Western Washington. Geologic studies of the Landfill have identified four lithologic units at the site. These units are recessional outwash, glacial till, advance outwash, and older undifferentiated deposits (OUD). Figure 3 (Harding, 1992) is a north-south cross section depicting the occurrence and variations in thickness of these units at the Landfill.

Two groundwater systems have been identified beneath the site: a local or Shallow Aquifer in the recessional and advance outwash deposits, and a regional or Deep Aquifer in the pre-Vashon deposits. Beneficial use of groundwater in the vicinity of the Landfill is limited to domestic wells withdrawing from the Deep Aquifer.

Shallow Aquifer: The Shallow Aquifer occurs continuously below the Landfill site in recessional and advance outwash deposits. The aquifer is perched and unconfined, ranges from 5 to 36 feet below ground surface and is between 35 and 50 feet thick. The perching layer is the highly oxidized, low hydraulic conductivity, upper surface of the OUD. Below the highly oxidized upper surface of the OUD, unsaturated conditions occur for over 70 feet before the Deep Aquifer is encountered. There are currently 12 monitoring wells installed in the Shallow Aquifer, six of which are monitored on a quarterly basis (MW-1, 4, 6, 10, 11, and 18). The six wells were selected for representativeness and location. Two additional wells (MW-26 and 27) are used to measure water levels only.

Deep Aquifer: The Deep Aquifer occurs between 130 and 150 feet below ground surface (average groundwater elevation of 510-feet mean sea level). The aquifer occurs in the pre-Vashon sand and gravel deposits and appears to be unconfined. There are currently three monitoring wells installed in the Deep Aquifer, one up-gradient (MW-25), and two down-gradient (MW-3 and MW-7). MW-9 was also installed in the Deep Aquifer but was decommissioned in 2001 after it was damaged in the Nisqually earthquake. MW-25 was installed at that time to provide upgradient monitoring. The Deep Aquifer is believed to discharge to the Cedar River located southwest of the site.

1.2.2. SITE REMEDIATION

In 1989, a low permeability bentonite Slurry Wall was installed around the refuse and keyed into the Shallow Aquifer perching unit. Three extraction wells were installed in the Shallow Aquifer beneath the refuse. Groundwater extraction commenced from the Shallow Aquifer within the Slurry Wall to reduce hydraulic heads sufficiently below water levels outside the Slurry Wall to maintain an inward hydraulic gradient. This maintains the water table surface below the level of deposited waste and an inward hydraulic gradient around the Landfill, minimizing the potential for migration of contaminants.

1.2.3. GROUNDWATER AND SLURRY WALL WATER LEVELS

After the 1994 Final Closure of the Landfill, infiltration through refuse was sufficiently reduced such that extraction was no longer necessary. Water levels on the interior of the Slurry Wall were monitored monthly together with four selected monitoring wells outside of the Slurry Wall. A comparison of these water levels monthly provided verification that water levels inside the Slurry Wall remain well below outside levels, confirming the Slurry Wall and cover were functioning properly.

In 2009, AMEC Geomatrix evaluated the conditions and effectiveness of the Slurry Wall and groundwater control system. It was determined that the piezometers and monitoring well network provided sufficient and valid water level information. Further, in the event water elevations within the Slurry Wall would begin to rise, pumping capacity was deemed adequate to counter a (0.5) foot/year rise thus maintaining hydraulic head differences and inward gradients. The evaluation also verified the continued suitability of the water level control system.

In 2014 KCSWD undertook an evaluation to determine what may be contributing to higher water levels measured within the Slurry Wall. Evaluation of cover penetrations at gas wells, piezometers and extraction wells were prioritized along with buried LFG laterals, headers, and condensate drops. This evaluation found minor tears in the cover due to settlement in three of 26 excavated cover penetrations. The repairs were completed in February 2015, and assessment concluded that the amount of infiltration through these failures would have no visible effect on water levels inside the Slurry Wall.

In 2015 KCSWD initiated further investigation and evaluation of environmental control systems at the Landfill. A technical memorandum, *Landfill Cover, Slurry Containment Wall, and Leachate Management Alternatives Technical Memorandum*, was prepared and concluded that the cover was performing to design specifications but recent precipitation had exceeded the historical average. Six alternatives were identified to address rising groundwater levels beneath waste with work continuing to assess the feasibility of implementation. As a part of this project, six piezometers were installed, four within the slurry wall and two outside. Additionally, gauging stations were installed on conveyances carrying stormwater to infiltration basins onsite. Water levels and flow were monitored using a network of transducers to better define flow and recharge dynamics. The initial water balance study was completed and the results documented in the *Landfill Cover Water Balance Technical Memorandum* in December 2017. A follow-up confirmation water balance study is scheduled to be completed in 2019.

In 2017, analysis of water level data noted that the minimum difference in hydraulic head between the inside of the Slurry Wall and outside had lessened and contingency pumping was initiated in June of 2017. Approximately 800,000 gallons of water were removed from within the Slurry Wall containment. Pumping activities have been effective to maintain the inward hydraulic gradient and separation between groundwater and the base of refuse.

Top of casing elevations for the wells in solid waste were last surveyed in March 2009. A follow-up effort to resurvey elevations in the North American Vertical Datum of 1988 (NAVD 88) is currently underway. Wells and piezometer within the Slurry Wall have already been surveyed and

updated to NAVD 88, with monitoring wells outside the slurry wall scheduled to be surveyed in spring of 2019 as a part of the on-going investigation and environmental control systems evaluation project. Once all elevations are updated, presentation and assessment of water levels will be switched to NAVD 88.

Figure 4 shows the historical levels of hydraulic head in monitoring wells located outside the Slurry Wall and water level measurements obtained inside the Slurry Wall.

1.2.4. WALSH LAKE DIVERSION DITCH

In the 1930's, the City of Seattle constructed the Walsh Lake Diversion Ditch (Ditch) to divert the water contaminated by the town of Taylor. The water was intercepted just above the natural confluence with Rock Creek, a tributary of the Cedar River in the Municipal Watershed, and conveyed 1.7 miles to a discharge point on the Cedar River downstream of the Landsburg Diversion Dam. The Ditch, flowing upgradient and along the north edge of the Landfill, was lined in selected areas around the same time that the slurry wall was constructed to reduce Shallow Aquifer recharge and thereby reduce hydraulic head in the vicinity of deposited waste.

The Ditch and adjacent slopes were prone to periodic failures due to the Ditch's problematic location in a steep ravine above Rock Creek. In a January 2009 storm event, a 300-foot section of the Ditch catastrophically failed, effectively disconnecting and dewatering the downstream section of the Ditch. Because the Ditch was no longer needed, Seattle Public Utilities did not repair it, but rather, in 2012 restored the confluence of the Walsh Lake and Rock Creek stream systems. Since this failure and restoration, there is no longer any flow in the Ditch adjacent to the Landfill.

CHAPTER 2: GROUNDWATER DATA EVALUATION

2.1. GROUNDWATER ELEVATIONS AND FLOW DIRECTION

Groundwater levels in individual wells have been plotted as a function of time (Figures 5 & 6). Groundwater flow directions were estimated based on water elevations recorded in monitoring wells screened in similar water-bearing zones (Appendix B). Upgradient and downgradient wells are determined by flow direction.

Shallow Aquifer: Piezometric flow maps, based on water levels recorded in the on-site monitoring wells, indicate a general aquifer flow to the west (Appendix B). The Slurry Wall is constructed of low permeability materials that prevent inward flow. The measured water levels for wells outside the Slurry Wall and piezometers inside are shown in Figure 4. Seasonal variation of up to eight feet in water level measurements has been observed for individual wells (Figure 5).

Deep Aquifer: Piezometric surface maps (Appendix B) based on the three monitoring wells indicate a westerly hydraulic flow direction, which sometimes flows southwesterly, depending on the season. A seasonal water level fluctuation up to 6 feet has been recorded in the three on-site monitoring wells. Water level fluctuation in these wells has lagged behind that of the shallow wells by about one month (Figure 6).

2.2. DATA EVALUATION METHODS

The analyte list for routine groundwater monitoring at the Landfill was assembled from parameters listed in WAC 173-200 – Washington State Ground Water Quality Standards (WSGWQS), including field and conventional parameters, dissolved metals, and volatile organic compounds (VOCs). Some of these analytes are useful in characterizing groundwater quality, as indicators of impacts to groundwater from LFG and leachate, or in screening for potentially harmful effects to human health and the environment. The data evaluation focuses on these analytes.

Environmental samples are collected, analyzed and evaluated by the procedures described in the Environmental Monitoring Quality Assurance Project Plan and Sampling Analysis Plan for Cedar Falls, Enumclaw and Hobart Closed Landfills (QAPP/SAP). The QAPP/SAP describes activities undertaken to ensure that analytical results meet data quality objectives (DQO's) including are representative of actual groundwater conditions. For this report, the graphical representation includes those parameters that have exceeded regulatory limits or/and have a visual trend. The water quality discussion is focused on exceedances, a trend table, graphs, and potentiometric maps.

2.3. GROUNDWATER CHEMISTRY RESULTS

This section presents results and interpretation of water chemistry evaluations performed for each groundwater monitoring well at the Landfill. The results are presented according to aquifer and location relative to the principal groundwater flow direction. Discussion

emphasis is on results obtained since the last annual groundwater evaluation report, which contains samples from the 4th quarter of 2017 through the 3rd quarter of 2018. Statistical comparisons have been compiled for three time periods: prior to Slurry Wall construction (October 1986 to April 1989); post Slurry Wall construction (April 1989 to 3rd quarter 2016); and, the last eight sampling periods (4th quarter 2016 through 3rd quarter, 2018).

2.3.1. LOWER LIMIT OF QUANTITATION

Changes made to the guidance for analytical testing methodologies covered by SW-846 (Test Methods for Evaluating Solid Waste) were implemented in 2017. One specific effect of these changes was to replace the Method Detection Limit (MDL) methodology with the Lower Limit of Quantitation (LLOQ) methodology as the basis for determining the lowest quantitative value of an analyte that can be reported. This affected all methods covered within SW-846.

The LLOQ is a performance based methodology that tests known standards repeatedly to create a calibration curve for each specific laboratory analysis method. Commonly, the lowest concentration of the (linear) calibration curve is set as the LLOQ. However, in some cases the LLOQ may be greater than the baseline curve concentration due to lab specific factors such as instrument sensitivity and method analytical uncertainty.

During the second quarter of 2017, a transition to the LLOQ methodology occurred for metals analysis, SW846 Method 6020B, and for volatile organics, SW846 Method 8260C. This resulted in revised reporting limits for many analytes. For trace metals analytes, the quantitation limit was typically lower than the previous reporting limit. For VOCs, limits varied higher and lower (or unchanged) due to analyte specific considerations. As a result of these changes, previously undetected trace metals are now being reported as quantified, as are three volatile compounds (1,1-dichlorethane, carbon disulfide, and dichlorodifluoromethane) at differing wells/dates. Volatile detections are not exceedances of the WSGWQS, but concentrations are being reported below previous reporting limits.

2.3.2. ANALYSIS OVERVIEW

Water quality analysis for the Shallow and Deep Aquifers are presented in this section. In general, water quality in both aquifers has improved over time and demonstrates stability in current conditions. Exceedances of the WSGWQS criteria that occurred during this reporting period are listed in Table 2-1. Descriptive statistical and trend tables of field and analytical data are presented in Appendix C for the Shallow and Deep Aquifers. The Post Slurry Wall Construction Long Term Trend Data is filtered by season (winter/summer) in order to be more representative of the entire time period (April 1989 to September 2016). Graphical representations of parameters with exceedances and/or visual trends are presented in Appendices D and E as time concentration plots. Two plots are constructed for each parameter: one for the period of record and a second covering the past five years of data. Raw data are contained in Appendix F.

The results are used collectively to indicate the possibility of groundwater contamination. Corroboration by several indicators is necessary before impacts from waste in-place can be considered a reasonable conclusion.

2.3.3. SHALLOW AQUIFER MONITORING WELL RESULTS

Quarterly groundwater monitoring has been performed by KCSWD in six shallow aquifer wells since 1986. Field and laboratory analysis results are discussed in this section. Numerical ranges reference the values from the last 8 data points, or from the last two years of samples. Wells are located north, south, and west of the Landfill (Figure 2).

MW-11 (Upgradient/Background Well)

MW-11 is located near the northeast corner of the site. It is also located near the Ditch, which may have been a source of recharge to the Shallow Aquifer prior to 2009. This well serves as an upgradient monitoring well for the Shallow Aquifer (see Figure 2).

Data collected from MW-11 indicate that slightly acidic conditions of 6.1 to 6.7 pH units prevail with regular exceedances of the field pH lower standard limit. Specific conductance, total dissolved solids, alkalinity, chloride, sulfate, nitrate, ammonia, iron, and manganese are low and relatively stable. The minimum, maximum, and mean for these parameters over the last eight sampling events are available in Table 2-2. There are no statistically significant short term trends in any monitored parameters.

Showing no signs of impacts, MW-11 is a good representation of ambient groundwater quality upgradient of the Landfill and is an adequate upgradient monitoring well.

MW-1, MW-4, MW-6, MW-10, & MW-18 (Side and Downgradient Wells)

MW-6 is located in the southeast corner of the site and is hydraulically side gradient to the Landfill. MW-1 is located near the southern boundary of the site. MW-10 is located southwest of the Landfill, while MW-18 and MW-4 are located west of the Landfill (see Figure 2). Piezometric head data indicate these last four wells are hydraulically downgradient of the Landfill. Groundwater in these five wells tends to be slightly acidic to neutral with pH ranges between 5.6 and 6.7. Chloride concentrations have decreased over time and stabilized at levels similar to upgradient conditions.

Wells MW-1, MW-10 and MW-18 generally exhibit either statistically significant long term decreasing trends, or no trend for all parameters. Wells MW-6 and MW-4 generally have fewer statistically significant long term decreasing trends (versus no trend found), with only three increasing long term trends found including magnesium for MW-4, and chloride and nitrate at MW-6. Chloride concentrations for MW-6 are similar to those found at MW-11. Also of note, specific conductance for MW-4 no longer has an increasing trend versus previous years. All Shallow Aquifer down and side gradient wells have similar nitrate concentrations to the background well, MW-11.

Field pH was below the lower limit for the WSGWQS secondary criteria in all wells for at least one field sampling event the past year. Arsenic exceeded the WSGWQS primary criteria in all samples analyzed after adoption of the LLOQ methodology except MW-4 where it remains undetected. Iron exceeded secondary standards in all MW-10 samples and three of four MW-1 samples. Manganese exceeded WSGWQS secondary criteria in all samples from MW-1, MW-3 and MW-10 and one sample for MW-18. No other water quality criteria were exceeded during this period.

No VOCs were detected in shallow wells, with the exception of carbon disulfide at MW-10 in the 4th quarter of 2017. However, this result was qualified as estimated (“JT” qualified) by the contract lab due to being reported below the LLOQ.

In general, water samples from MW-1, MW-6 and MW-10 have relatively higher levels of specific conductance, total dissolved solids, alkalinity, calcium, iron, and manganese when compared to upgradient groundwater. MW-4 and MW-18 parameter concentrations have declined and stabilized at levels similar to those upgradient for most parameters. The water quality conditions found in MW-4 are similar to those at MW-11 and indicate no remaining impacts from landfilling activities. The minimum, maximum, and mean for these parameters over the last eight sampling events are listed in Table 2-2. Short term, there are few statistically significant decreasing trends and none increasing for these wells. In general, the limited number of statistically significant long term increasing trends versus decreasing or no trend found indicates water quality is stable or improving in the Shallow Aquifer.

2.3.4. DEEP AQUIFER MONITORING WELL RESULTS

Quarterly groundwater monitoring has been performed by KCSWD in three deep aquifer wells since 1986. Field and laboratory analysis results are discussed in this section. Numerical ranges reference the values from the last 8 data points, or from the last two years of samples. Wells are located north, south, and west of the Landfill (Figure 2).

MW-25 (Upgradient/Background Well)

MW-25 is located north of the Landfill and based on piezometric head data, is hydraulically upgradient of the site. This well was installed in 2001 to replace MW-9, which was damaged in the 2001 Nisqually earthquake. The conditions found in MW-25 are considered representative of background water quality in the Deep Aquifer.

Water in MW-25 is slightly alkaline. Alkalinity, chloride, sulfate, and iron levels are low and stable. The minimum, maximum, and mean for these parameters over the last eight sampling events are available in Table 2-2. There are no statistically significant short term decreasing trends for MW-25. Long term trends show a mix of increasing and decreasing for conventional and metal parameters. Magnesium is the only parameter with a newly increasing trend.

As an upgradient well, MW-25 exceeded the WSGWQS criteria for arsenic in all recent samples.

Dichlorodifluoromethane was detected in all four samples in MW-25, but was not an exceedance of WSGWQS or Federal Drinking Water criteria. There were no other volatile organic compounds detected in MW-25 during this period.

MW-7 & MW-3 (Downgradient Wells)

MW-7 is located south of the Landfill, and MW-3 is located west of the Landfill. Based on piezometric head data, these two wells are hydraulically down gradient of the site.

Water in MW-7 and MW-3 is slightly alkaline, with mean alkalinities of 135.3 and 70.1 mg/L, respectively. Specific conductance, total dissolved solids, alkalinity, sulfate, calcium, magnesium, potassium and sodium levels in MW-7 are higher than those in upgradient well MW-25. MW-3 has higher specific conductance and alkalinity, and higher concentrations of total dissolved solids, sodium, and manganese. No volatile organics were detected in these wells. The minimum, maximum, and mean for these parameters over the last eight sampling events are available in Table 2-2.

Assessing trends, there are no statistically significant short term trends (increasing or decreasing) in MW-3 and MW-7, except for increasing calcium for MW-7. Both monitoring points however have a mix of long term increasing and decreasing trends. For MW-7, long term trends are either decreasing or unchanged for metals and conventionals, with the exception of pH increasing. MW-3 has long term increasing trends for specific conductance, chloride, sulfate, total dissolved solids, and five metals (calcium, magnesium, manganese, potassium, and sodium), all of which are major iconic species. Concentrations of these parameters remain relatively low, and except for sodium, calcium, and manganese, are similar to upgradient well MW-25. Monitoring will continue to assess any future changes to water quality characteristics.

Recent changes to lower reporting limits resulted in quantifiable results for 1,1-dichloroethane in MW-7. Declining concentrations had been tracked from 1992 through 2008 when it was last detected above the 0.2 µg/L reporting limit. The two most recent samples were quantified at 0.102 µg/L and a non-detect (0.1 µg/L), consistent with the long term decline, and exhibited by a short term decreasing trend for MW-7. No other volatile organic compounds were detected in MW-3 or MW-7.

Similar to the Shallow Aquifer, arsenic was detected in all MW-3 and MW-7 samples for the past year due to the adoption of the LLOQ methodology. These detections are exceedances of the primary WSGWQS criteria; however, results are also below or commensurate with natural background concentrations for groundwater in the State of Washington.

2.3.5. SLURRY WALL PERFORMANCE

The slurry wall containment isolates the Shallow Aquifer beneath the Landfill from the local groundwater flow system. Pumping wells installed beneath the solid waste and inside the Slurry Wall have lowered the groundwater table below the base of refuse. The water elevation outside of the Slurry Wall has remained consistently above the water elevation inside (see Figure 4). As a

result, an inward hydraulic gradient has been created resulting in a system which reduces the possibility of breakthrough of contaminants and off-site transport.

Concurrent with the construction of the Slurry Wall, the northern half of the Landfill was closed with an HDPE final cover. The southern half was later closed in 1994. Consequently, local recharge to the aquifer has been reduced.

Six indicators have been used to evaluate the site remediation: chloride, arsenic, manganese, 1,1-Dichloroethane, 1,1,1-Trichloroethane, and *cis*-1,2-Dichloroethene. Chloride is an early indicator of leachate, and manganese is sensitive to redox conditions. Their movement through groundwater is controlled by different chemical processes. Chloride migration is not retarded by such processes as adsorption, cation exchange, biological uptake or redox processes. The distribution of manganese, however, is strongly controlled by redox processes. Reducing conditions permit manganese to dissolve and be transported in groundwater. Reducing conditions prevail when oxygen is depleted by waste degradation and sustained by the presence of BOD and anaerobic metabolism. Thus, manganese may be an indicator of Landfill impacts.

Chloride in all of the down and side gradient wells has been reduced to levels found in MW-11 (background). Manganese levels have been reduced in all wells, but remain elevated relative to MW-11 in MW-1, MW-10 and MW-18.

Until recently, arsenic had only been detected consistently in one Shallow Aquifer well, MW-10, and one Deep Aquifer well, MW-25. Recent detections in all wells (except MW-4) are due to the switch to LLOQ reporting methodology. For both MW-10 and MW-25, arsenic concentrations have been consistently decreasing over time.

Organic compounds have been detected with relatively low frequency and at low level both prior to and since construction of the Slurry Wall. The concentration levels for *cis*-1,2-dichloroethene, 1,1-dichloroethane, and 1,1,1-trichloroethane have been used to evaluate the success of remediation indicated by their decrease over time. There have been no detections of these compounds in any shallow wells since 2008.

A summary of the performance of the Slurry Wall and drawdown wells showing water quality prior to remediation and after remediation are presented in Table 2-3.

This water quality evaluation in conjunction with water level data shown in the potentiometric mapping and the trend analyses demonstrates that the Slurry Wall is functioning as designed: maintaining groundwater elevation separation below the waste by preventing groundwater migration inside the wall perimeter. Elevated groundwater levels below waste are attributed to increased cover infiltration due to higher precipitation levels since 2009.

CHAPTER 3: SUMMARY AND CONCLUSIONS

The conclusions of this groundwater quality evaluation report are presented according to aquifer and time period.

3.1. SHALLOW AQUIFER

The Shallow Perched Aquifer is an unconfined water table aquifer that has historically saturated lower portions of the solid waste beneath certain areas of the site. Since completion of the Slurry Wall remediation construction in 1989, the shallow water table no longer comes into contact with refuse, and the groundwater gradient around the site has been altered to minimize off-site transport from beneath the Landfill.

Information presented in this report suggests that on-site monitoring wells installed in the Shallow Aquifer and located hydraulically downgradient of the Landfill may have historically been influenced by landfilling activities. When monitoring began in 1986, the downgradient wells had elevated levels of some leachate indicator constituents with respect to the upgradient wells. Since 1986, these constituents have become progressively less concentrated in downgradient wells, as a result of improved landfill site conditions and Shallow Aquifer remediation activities, particularly installation of the low permeability bentonite Slurry Wall.

Wells in the Shallow Aquifer displaying impacts from landfilling activities consisted of MW-1, MW-10, MW-6, and to a lesser extent, MW-18 and MW-4. These wells are located along the west and south perimeter of the landfill. Concentrations were highest prior to completion of the Slurry Wall. Trend analyses show that statistically significant decreases in long term trends of indicator parameters have occurred in the side and down gradient wells. In general, water quality in this aquifer has improved and demonstrates stability in current conditions.

VOCs associated with Shallow Aquifer impact prior to and in the early remediation phase have decreased with only three estimated volatile detections reported since December of 2008, excluding suspected analytical laboratory contaminant volatile results. Recent detections are attributed to lower detection limits (below previous reporting limits), which further confirms that concentrations have declined and are detectable only infrequently.

Current water quality conditions in the Shallow Aquifer continue to approach background constituent concentrations and no future increases in contaminant levels are expected given current site wide trends.

3.2. DEEP AQUIFER

The refuse is located in excess of 100 feet above the Deep Aquifer, and is separated from the deeper water bearing zone by about 80 feet of dry or moist soils. A low permeability (10^{-6} cm/sec) perching layer of the OUD is continuous beneath the site and separates the two hydrogeologic systems. The lack of moisture in the soils indicates that hydraulic connection between the fill and

the groundwater is not strong and the soil capacity to retard contaminants is enhanced because of unsaturated conditions.

General geochemistry parameters at MW-7 are elevated relative to the upgradient well, but all have shown relatively stable concentrations over both the long term and short term periods. In addition, the concentrations of these parameters are below both Federal Drinking Water and WSGWQS exceedance criteria. The frequency of VOC detections in the Deep Aquifer has decreased considerably over time, with only dichlorodifluoromethane detected regularly in MW-25, an upgradient well, and 1,1-dichloroethane having recent detections in MW-7 due to the change in laboratory detection limit methodology. Both of these detections are below the WSGWQS criteria.

The groundwater quality in the deep aquifer has improved over time.

3.3. RECOMMENDATIONS

Recommendations moving forward for Hobart Closed Landfill are:

- Maintain engineered controls, including the engineered cover, the leachate extraction system, landfill gas treatment system, and the stormwater management structures.
- Continue monitoring water level, field parameters and groundwater sampling on a quarterly basis at all wells in the current monitoring network, and landfill gas compliance probe monitoring on a monthly basis.
- Continue work on developing and assessing feasibility of alternatives for addressing increased cover infiltration/rising groundwater levels.
- Perform appropriate pumping needed to maintain hydraulic gradients and waste isolation.

NOTES:													
Change is computed as the difference between Current and Pre slurry wall period medians													
ID Insufficient Data. The number of detections is less than 3													
> Indicates the current value is under detection limit (DL) and difference is between DL and Pre slurry wall period median													
-- Unable to compute concentration changes													
Gradient location means location of monitoring well relative to the hydraulic gradient of the Recessional Outwash Aquifer and the solid waste													
Shading indicates a negative change in concentration

RE: Potentiometric Groundwater Surface Mapping & Groundwater Velocity Calculations
Water Year 2017–2018 Results
Hobart Closed Landfill, King County, Washington
Project No. 1033596 – Task 23.14.137.44

The King County Water and Land Resources Division (WLR Division) submits this memorandum report on groundwater conditions during the 2017–2018 water year for the shallow and deep aquifers beneath the Hobart Closed Landfill (Landfill), in accordance with the *Proposal for Potentiometric Groundwater Surface Maps & Groundwater Velocity Calculations* (KC, 2018). King County Solid Waste Division (SWD) personnel measured depth to water at the Landfill quarterly during the 2017–2018 water year. These measurements were received by the WLR Division on October 26, 2018 and where possible, were used to:

1. Evaluate the potentiometric groundwater surface during the quarters with the lowest and highest water levels for the shallow and deep aquifers;
2. Determine the groundwater flow direction and horizontal gradient during the quarters with the lowest and highest water levels for the shallow and deep aquifers; and
3. Calculate the groundwater flow velocities during the quarters with the lowest and highest water levels for the shallow and deep aquifers.

There have been no significant changes in the groundwater flow direction or velocity for both the shallow and deep aquifers during the 2017–2018 water year since the previous report submitted for the 2016–2017 water year monitoring event.

Groundwater Elevation Data

SWD measured groundwater levels quarterly during the 2017–2018 water year at eleven monitoring wells completed in the shallow or deep aquifers. Groundwater levels were also

measured in five wells located inside the slurry wall surrounding the landfill. Table B-1 lists the well identifications, XY location data, top of casing elevations, measured depth to water levels, and calculated groundwater elevations for the shallow and deep aquifers, as well as for the water-bearing zone inside the slurry wall.

The highest groundwater elevations were measured during the second quarter monitoring event performed on February 26, 2018. The lowest groundwater elevations were measured during the fourth quarter monitoring event performed on August 16, 2018.

Figures B-1 and B-2 show well locations and groundwater elevations for the shallow aquifer for the quarters with the highest and lowest water levels during the 2017–2018 water year, respectively. Inferred groundwater potentiometric surface contours were mapped in the shallow aquifer for the quarter with the highest water levels during the 2017–2018 water year. The range of the groundwater levels during the quarter with the lowest water levels did not allow for a representative groundwater potentiometric surface contour to be drawn.

During the 2017–2018 water year, water levels measured inside the slurry wall ranged from approximately two to seven feet below groundwater levels outside the wall, indicating hydraulic separation from the shallow aquifer.

Figures B-3 and B-4 show well locations, groundwater elevations, and inferred groundwater potentiometric surface contours in the deep aquifer for the quarters with the highest and lowest water levels during the 2017–2018 water year, respectively.

Direction of Groundwater Flow

Figures B-1 and B-2 show groundwater potentiometric surface contours and interpreted groundwater flow directions in the shallow aquifer, based on the quarters in the 2017–2018 water year having the lowest and highest water levels. Groundwater elevations indicate that groundwater generally flowed towards the west around the slurry wall during the quarter with the highest water levels in the shallow aquifer. Based on elevations only, there is possible west-northwest component of water flowing around the slurry wall and to the west-northwest during the quarter with the lowest water levels in the shallow aquifer.

The groundwater elevation at MW-16 was higher than elevations observed at other shallow aquifer wells by about three to eight feet. This may be caused by groundwater mounding upgradient of the landfill as groundwater approaches the slurry wall and flows around the north and south sides of the slurry wall.

Figures B-3 and B-4 show groundwater potentiometric surface contours and interpreted groundwater flow directions in the deep aquifer, based on the 2017–2018 water year quarterly measurements. Groundwater elevations indicate that groundwater generally flowed west to west-southwest during quarters with the lowest and highest water levels in the deep aquifer.

Groundwater Parameters

Horizontal groundwater velocity was calculated using the following formula:

where:
$$v = \frac{I}{n_{eff}} K \frac{\Delta H}{\Delta L}$$

v = Groundwater velocity [L/t]

n_{eff} = Effective porosity [dimensionless]

K = Hydraulic conductivity [L/t]

$\frac{\Delta H}{\Delta L}$ = Hydraulic gradient [L/L]

Horizontal groundwater velocity was calculated for the shallow aquifer outside the slurry wall and for the deep aquifers below the landfill. The hydraulic conductivity and effective porosity values were based on the ranges referred to in the Potentiometric Groundwater Surface Mapping and Groundwater Velocity Calculation – Hobart Closed Landfill (Aspect, 2010) and reported in various documents (HWA, 2003; Beck & SEA, 1984; Galster & Laprade, 1991).

The hydraulic gradient was determined from the potentiometric surface maps (Figures B-1 through B-4). The hydraulic gradient in the shallow aquifer was using groundwater elevations measured in wells completed along the south side of the slurry wall, as was possible. The data for the lowest quarter did not allow for groundwater contour mapping and calculation of hydraulic gradient. The gradient in the deep aquifer was calculated using the three wells measured during the 2017–2018 water year.

Table B-2 presents a summary of the groundwater parameters used to calculate a groundwater velocity for both aquifers.

The velocity calculated for the shallow aquifer was 9.1 ft/day for the highest quarter. The data for the lowest quarter did not allow for groundwater contour mapping and calculation of velocity. The velocities calculated for the deep aquifer were 0.024 and 0.026 ft/day for the highest and lowest quarters, respectively. The velocities were all within the range of groundwater velocities calculated during the 2016–2017 water year.

Notes:

Water level measurements made by KCSWD personnel.

Reference datum for XY coordinates is based on Washington State Plane grid system.

Elevations reported in feet above Mean Sea Level (MSL) based on the National Geodetic Vertical Datum, 1929.

Lowest groundwater levels reflect the 2017-2018 Water Year minimum groundwater elevations, observed on August 16, 2018.

Highest groundwater levels reflect the 2017-2018 Water Year maximum groundwater elevations, observed on February 26, 2018.

NM No measurement - blockage in well casing prevented access to water level.

NA Not applicable

Table B-2: Groundwater Parameters: 2017 - 2018 Water Year

Hobart Closed Landfill
King County, Washington

Groundwater Zone Adjacent to or Beneath Landfill	Monitoring Event	Date	Horizontal Hydraulic Conductivity (K)		Horizontal Hydraulic Gradient (DH/DL)	Effective Porosity (n_{eff})	Horizontal Groundwater Velocity (v)	General Groundwater Flow Direction
			(cm/s)	(ft/d)	(ft/ft)		(ft/d)	
Shallow Aquifer	Highest Groundwater Levels	2/26/2018	0.3	800	0.0028	25%	9.1	W
	Lowest Groundwater Levels	8/16/2018	0.3	800	NA	25%	NA	W*
Deep Aquifer	Highest Groundwater Levels	2/26/2018	0.00007	0.2	0.031	25%	0.024	WSW
	Lowest Groundwater Levels	8/16/2018	0.00007	0.2	0.032	25%	0.026	

Notes:

Shallow aquifer parameters (horizontal hydraulic conductivity and effective porosity values) from

Potentiometric Surface Maps and Aquifer Flow Calculations: Hobart Landfill (HWA, 2003).

Deep aquifer hydraulic conductivity obtained from *Groundwater Geology/Quality*

Investigations for the Rural Landfills: Report for the KCSWD (Beck & SEA, 1984).

Lowest groundwater levels reflect the 2017-2018 Water Year minimum groundwater elevations, observed on August 16, 2018.

Highest groundwater levels reflect the 2017-2018 Water Year maximum groundwater elevations, observed on February 26, 2018.

W west, WSW West-southwest

*Possible WNW component

NA Not applicable

Legend

- MW-4** Well Completed in Shallow Aquifer
xxx.xx
- MW-3** Other Monitoring Well
- 626** Inferred Shallow Aquifer Groundwater Elevation Contour (feet MSL)
- Inferred Horizontal Groundwater Flow Path
- Slurry Wall

Note:
 NM=not measured
 Groundwater level measurements made
 on February 26, 2018.
