RE: Hobart Closed Landfill 2020 Annual Groundwater Data Evaluation Report

The purpose of this memorandum is to transmit a copy of the Hobart Closed Landfill 2020 Annual Groundwater Data Evaluation Report for your review. This report includes an executive summary, site specific summary, exceedances table, trend test table, recommendations, potentiometric surface maps (p-maps), time-concentration plots of parameters of interest, and field and lab data in PDF format. The groundwater quality discussion is focused on exceedances, trend table, graphs, and p-maps.

We will continue to provide these reports on groundwater data evaluation as part of the reporting requirements. We will address any revisions and concerns that you might have about this document in our next annual report. We appreciate your comments to improve these reports.

If you have any questions regarding this report, please contact me at me at (206) 263-0608, or via email at nusova@kingcounty.gov.

EXECUTIVE SUMMARY

This annual report presents the Hobart Closed Landfill (Landfill) evaluation of groundwater quality and water level data collected from October 1986 through September 2020.

Groundwater investigations in the mid-1980s led to remediation design and installation of a bentonite Slurry Wall to isolate the shallow groundwater beneath the refuse from the aquifer present below the Landfill. The groundwater beneath the Landfill was pumped out and a lower water level inside the Slurry Wall has been maintained since 1989. Final closure of the north half of the Landfill was completed in 1990 and of the south half in 1994, with the placement of a High Density Polyethylene (HDPE) cap, drainage layer, and vegetative layer over the refuse. From final closure until recently, pumping had not been required to maintain water levels below refuse and an inward gradient across the Slurry Wall.

Groundwater quality and water level data are collected quarterly and reviewed to summarize and evaluate groundwater quality at the Landfill and determine changes, if any. Water quality data includes samples collected from nine monitoring wells.

Groundwater flow beneath the Landfill has been evaluated by a licensed hydrogeologist. The report is included as Appendix B. The groundwater beneath the Landfill occurs in two aquifers; the Shallow Aquifer and the Deep Aquifer. In both zones, the water generally flows in a westerly direction.

During the current evaluation period, groundwater in both aquifers shows continued improvements in water quality characteristics when compared with pre-Slurry Wall installation groundwater quality. The demonstrated water quality improvements together with the maintained head differential across the Slurry Wall provide indications that the system is continuing to function as designed. Monitoring at the Landfill will continue throughout the required post closure period.

The water levels inside and outside the Slurry Wall are monitored quarterly. This data is used to evaluate whether the water levels within the Slurry Wall remain below the base of waste, and that the water levels inside are sufficiently below those outside the Slurry Wall so as to maintain an inward hydraulic gradient and minimize the potential for migration of contaminants. Since approximately 2009, seasonal high water levels within the Slurry Wall have successively increased due to higher than historical rates of rainfall, increasing the infiltration through the cover. In 2014, an evaluation of cover integrity at geomembrane penetrations was conducted and repairs were made in three locations in early 2015. Continued investigative efforts are underway to evaluate the environmental control systems. A contingency plan to pump and haul water to treatment was activated in 2017. This action helps maintain hydraulic gradients and waste isolation. An evaluation of the containment system (i.e. landfill cover, groundwater, landfill gas control, treatment, and landfill gas monitoring network) is being performed. These evaluations will determine if modifications are needed to achieve termination of post-closure status for the closed landfill.

PURPOSE

The purpose of this report is to provide an annual update on groundwater quality and water level data collected at the Landfill in accordance with WAC 173-304-405 (4)(d). The focus will be on the data collected during the last year, from October 2019 through September 2020. Historical data will be used as a comparison and to provide context for these results. Based on this analysis, further recommendations will be made as to how to continue to monitor the groundwater quality at the Landfill.

CHAPTER 1: LANDFILL OVERVIEW

1.1. OBJECTIVES

The objectives of this groundwater quality evaluation report for the Landfill are as follows:

- Review groundwater quality data from September 1986 through September 2020.
- Perform statistical analyses to evaluate any water quality trends, and to compare water quality between monitoring wells.
- Compare water quality data with water quality standards. Document any exceedances of Washington State Groundwater Quality Standards criteria.
- Determine whether any exceedances or trends as described above can be attributed to the Landfill.

1.2. SITE DESCRIPTION

The Landfill is located on 276th Street Southeast, between the towns of Hobart and Ravensdale, about 25 miles southeast of Seattle (Figure 1). The Landfill is owned by King County. It was operated and is maintained by the King County Solid Waste Division (KCSWD). It occupies approximately 75 acres, of which about 35 acres have been used for refuse disposal.

Prior to the early 1950s, the Landfill site was utilized as a sand and gravel pit. Landfilling activities began in the 1950s, with refuse being placed in the former sand and gravel pit. Open burning of refuse occurred until the early 1960s. From the early 1960s to 1990, refuse was placed in a controlled manner, utilizing compaction and daily cover.

A landfill site characterization in August 1983 included installation and sampling of four groundwater monitoring wells and characterization of surficial soils. Expanded site characterizations were performed between August 1985 and March 1986 and included an additional three wells installed in solid waste, and 22 wells installed in native soils surrounding the Landfill. Quarterly groundwater monitoring is currently performed in nine wells, of which six are in the Shallow Aquifer and three are in the Deep Aquifer (Table 1.1). The Landfill site map (Figure 2) shows the monitoring well locations.

Water quality impacts to the Shallow Aquifer were detected on site, triggering remedial activities in the Shallow Aquifer. Site remediation occurred during 1988 and 1989, including construction of a low permeability soil and bentonite slurry cutoff wall (Slurry Wall) around the Landfill. Site remediation is further described in Section 1.2.2.

In 1990, an HDPE final cover with a gas collection system was installed over 14 acres of the solid waste at the northern half of the Landfill (Phase 1 closure). In 1994, the remaining southern portion of the Landfill was closed under the Phase 2 closure project. This included: construction of a final cover and landfill gas (LFG) collection field over the south half of the Landfill; modifications and repairs to the existing LFG flare system; and, utilization of existing infiltration basins for stormwater runoff.

1.2.1. GEOLOGY AND HYDROGEOLOGY

The Landfill site characterization, including history, hydrogeology, and details regarding the Slurry Wall, has been documented in the reports listed in the References section. This section presents a summary of these reports' findings.

The Landfill is located within the Puget Sound lowlands of Western Washington. Geologic studies of the Landfill have identified four lithologic units at the site. These units are recessional outwash, glacial till, advance outwash, and older undifferentiated deposits (OUD). Figure 4 (Harding, 1992) is a north-south cross section depicting the occurrence and variations in thickness of these units at the Landfill.

Two groundwater systems have been identified beneath the site: a local or Shallow Aquifer in the recessional and advance outwash deposits, and a regional or Deep Aquifer in the pre-Vashon deposits. Beneficial use of groundwater in the vicinity of the Landfill is limited to domestic wells withdrawing from the Deep Aquifer.

Shallow Aquifer: The Shallow Aquifer occurs continuously below the Landfill site in recessional and advance outwash deposits. The aquifer is perched and unconfined, ranges from 5 to 36 feet below ground surface and is between 35 and 50 feet thick. The perching layer is the highly oxidized, low hydraulic conductivity upper surface of the OUD. Below the highly oxidized upper surface of the OUD, unsaturated conditions occur for over 70 feet before the Deep Aquifer is encountered. There are currently 12 monitoring wells installed in the Shallow Aquifer, six of which are monitored on a quarterly basis (MW-1, 4, 6, 10, 11, and 18). The six wells were selected for representativeness and location. Additional wells (MW-16, 21, 22, 26 and 27) are used to measure water levels only. In addition, four samples were collected at MW-26 in the 4th quarter of 2019 through 3rd quarter of 2020 and these results are included in Appendix F.

Deep Aquifer: The Deep Aquifer occurs between 130 and 150 feet below ground surface (average groundwater elevation of 510-feet mean sea level). The aquifer occurs in the pre-Vashon sand and gravel deposits and appears to be unconfined. There are currently three monitoring wells installed in the Deep Aquifer, one up-gradient (MW-25), and two down-gradient (MW-3 and MW-7). MW-9 was also installed in the Deep Aquifer but was decommissioned in 2001 after it was damaged in the Nisqually earthquake. MW-25 was installed at that time to provide upgradient monitoring. The Deep Aquifer is believed to discharge to the Cedar River located southwest of the site.

1.2.2. SITE REMEDIATION

In 1989, a low permeability bentonite Slurry Wall was installed around the refuse and keyed into the Shallow Aquifer perching unit. Three extraction wells were installed in the Shallow Aquifer beneath the refuse. Groundwater extraction commenced from the Shallow Aquifer within the Slurry Wall to reduce hydraulic heads sufficiently below water levels outside the Slurry Wall to maintain an inward hydraulic gradient. This maintains the water table surface below the level of deposited waste and an inward hydraulic gradient around the Landfill, minimizing the potential for migration of contaminants.

1.2.3. GROUNDWATER AND SLURRY WALL WATER LEVELS

After the 1994 Final Closure of the Landfill, infiltration through refuse was sufficiently reduced such that extraction was no longer necessary. Water levels on the interior of the Slurry Wall were monitored monthly together with four selected monitoring wells outside of the Slurry Wall. A comparison of these water levels monthly provided verification that water levels inside the Slurry Wall remain well below outside levels, confirming the Slurry Wall and cover were functioning properly.

After noticing changes in water levels, KCSWD initiated investigation and evaluation. In 2009, AMEC Geomatrix evaluated the conditions and effectiveness of the Slurry Wall and groundwater control system. It was determined that the piezometers and monitoring well network provided sufficient and valid water level information. Further, in the event water elevations within the Slurry Wall would begin to rise, pumping capacity was deemed adequate to counter a (0.5) foot/year rise thus maintaining hydraulic head differences and inward gradients. The evaluation also verified the continued suitability of the water level control system.

In 2014 KCSWD undertook an evaluation to determine what may be contributing to higher water levels measured within the Slurry Wall. Evaluation of cover penetrations at gas wells, piezometers and extraction wells were prioritized along with buried LFG laterals, headers, and condensate drops. This evaluation found minor tears in the cover due to settlement in three of 26 excavated cover penetrations. The repairs were completed in February 2015, and assessment concluded that the amount of infiltration through these failures would have no visible effect on water levels inside the Slurry Wall.

In 2015 KCSWD initiated further investigation and evaluation of environmental control systems at the Landfill. A technical memorandum, *Landfill Cover, Slurry Containment Wall, and Leachate Management Alternatives Technical Memorandum*, was prepared and concluded that the cover was performing to design specifications but recent precipitation had exceeded the historical average. Six alternatives were identified to address rising groundwater levels beneath waste with work continuing to assess the feasibility of implementation. As a part of this project, six piezometers were installed, four within the slurry wall and two outside. Additionally, gauging stations were installed on conveyances carrying stormwater to infiltration basins onsite. Water levels and flow were monitored using a network of transducers to better define flow and recharge dynamics. The initial water balance study was completed, and the results documented in the *Landfill Cover Water Balance Technical Memorandum* in December 2017. A follow-up confirmation water balance study was completed in 2019 with findings confirmed in 2019.

In 2017, analysis of water level data noted that the minimum difference in hydraulic head between the inside of the Slurry Wall and outside had lessened and contingency pumping was initiated in June of 2017. Approximately 800,000 gallons of water were removed from within the Slurry Wall containment. Pumping activities have been effective to maintain the inward hydraulic gradient and separation between groundwater and the base of refuse. Upgrades to leachate extraction wells were performed in 2019.

Top of casing elevations for the wells in solid waste were last surveyed in March 2009. A follow-up effort to resurvey elevations in the North American Vertical Datum of 1988 (NAVD 88) has

been recently performed with survey data being incorporated into KCSWD base maps and reports. Wells and piezometer within the Slurry Wall have previously been surveyed and updated to NAVD 88, with monitoring wells outside the slurry wall. Once all elevations are updated, presentation and assessment of water levels will be switched to NAVD 88.

Figure 5 shows the historical levels of hydraulic head in monitoring wells located outside the Slurry Wall and water level measurements obtained inside the Slurry Wall.

1.2.4. WALSH LAKE DIVERSION DITCH

In the 1930's, the City of Seattle constructed the Walsh Lake Diversion Ditch (Ditch) to divert the water contaminated by the town of Taylor. The water was intercepted just above the natural confluence with Rock Creek, a tributary of the Cedar River in the Municipal Watershed, and conveyed 1.7 miles to a discharge point on the Cedar River downstream of the Landsburg Diversion Dam. The Ditch, flowing upgradient and along the north edge of the Landfill, was lined in selected areas around the same time that the slurry wall was constructed to reduce Shallow Aquifer recharge and thereby reduce hydraulic head in the vicinity of deposited waste.

The Ditch and adjacent slopes were prone to periodic failures due to the Ditch's problematic location in a steep ravine above Rock Creek. In a January 2009 storm event, a 300-foot section of the Ditch catastrophically failed, effectively disconnecting and dewatering the downstream section of the Ditch. Because the Ditch was no longer needed, Seattle Public Utilities did not repair it, but rather, in 2012 restored the confluence of the Walsh Lake and Rock Creek stream systems. Since this failure and restoration, there is no longer any flow in the Ditch adjacent to the Landfill.

CHAPTER 2: GROUNDWATER DATA EVALUATION

2.1 GROUNDWATER ELEVATIONS AND FLOW DIRECTION

Groundwater levels in individual wells have been plotted as a function of time (Figures 6 and 7). Groundwater flow directions were estimated based on water elevations recorded in monitoring wells screened in similar water-bearing zones (Appendix B). Upgradient and downgradient wells are determined by flow direction.

Shallow Aquifer: Piezometric flow maps, based on water levels recorded in the on-site monitoring wells, indicate a general aquifer flow to the west (Appendix B). The Slurry Wall is constructed of low permeability materials that prevent inward flow. The measured water levels for wells outside the Slurry Wall and piezometers inside are shown in Figure 5. Seasonal variation of up to six feet in water level measurements has been observed for individual wells (Figure 6).

Deep Aquifer: Piezometric surface maps (Appendix B) based on the three monitoring wells indicate a westerly hydraulic flow direction, which sometimes flows southwesterly, depending on the season. A seasonal water level fluctuation up to three feet has been recorded in the three on-site monitoring wells. Water level fluctuation in these wells has lagged behind that of the shallow wells by about one month (Figure 7).

2.2 DATA EVALUATION METHODS

The analyte list for routine groundwater monitoring at the Landfill was assembled from parameters listed in WAC 173-200 – Washington State Ground Water Quality Standards (WSGWQS), including field and conventional parameters, dissolved metals, and volatile organic compounds (VOCs). Some of these analytes are useful in characterizing groundwater quality, as indicators of impacts to groundwater from LFG and leachate, or in screening for potentially harmful effects to human health and the environment. The data evaluation focuses on these analytes.

Environmental samples are collected, analyzed and evaluated by the procedures described in the Environmental Monitoring Quality Assurance Project Plan and Sampling Analysis Plan for Cedar Falls, Enumclaw and Hobart Closed Landfills (QAPP/SAP). The QAPP/SAP describes activities undertaken to ensure that analytical results meet data quality objectives (DQO's) including are representative of actual groundwater conditions. For this report, the graphical representation includes those parameters that have exceeded regulatory limits or/and have a visual trend. The water quality discussion is focused on exceedances, a trend table, graphs, and potentiometric maps.

2.3 GROUNDWATER CHEMISTRY RESULTS

This section presents results and interpretation of water chemistry evaluations performed for each groundwater monitoring well at the Landfill. The results are presented according to aquifer and location relative to the principal groundwater flow direction. Discussion emphasis is on results obtained since the last annual groundwater evaluation report, which contains samples from the 4th

quarter of 2019 through the 3rd quarter of 2020. Statistical comparisons have been compiled for three time periods: prior to Slurry Wall construction (October 1986 to April 1989); post Slurry Wall construction (April 1989 to 3rd quarter 2018); and, the last eight sampling periods (4th quarter 2018 through 3rd quarter, 2020).

2.3.1 LOWER LIMIT OF QUANTITATION

Changes made to the guidance for analytical testing methodologies covered by SW-846 (Test Methods for Evaluating Solid Waste) were implemented in 2017. One specific effect of these changes was to replace the Method Detection Limit (MDL) methodology with the Lower Limit of Quantitation (LLOQ) methodology as the basis for determining the lowest quantitative value of an analyte that can be reported. This affected all methods covered within SW-486.

The LLOQ is a performance based methodology that tests known standards repeatedly to create a calibration curve for each specific laboratory analysis method. Commonly, the lowest concentration of the (linear) calibration curve is set as the LLOQ. However, in some cases the LLOQ may be greater than the baseline curve concentration due to lab specific factors such as instrument sensitivity and method analytical uncertainty.

During the second quarter of 2017, a transition to the LLOQ methodology occurred for metals analysis, SW846 Method 6020B, and for volatile organics, SW846 Method 8260C. This resulted in revised reporting limits for many analytes. For trace metals analytes, the quantitation limit was typically lower than the previous reporting limit. For VOCs, limits varied higher and lower (or unchanged) due to analyte specific considerations. As a result of these changes, previously undetected trace metals are now being reported as quantified, as are a few volatile compounds (1,1-dichloroethane, chloroform, dichlorodifluoromethane, and vinyl chloride) at differing wells/dates. Volatile detections are not exceedances of the WSGWQS, and concentrations are being reported below previous reporting limits.

2.3.2 ANALYSIS OVERVIEW

Water quality analysis for the Shallow and Deep Aquifers are presented in this section. In general, water quality in both aquifers has improved over time and demonstrates stability in current conditions. Exceedances of the WSGWQS criteria that occurred during this reporting period are listed in Table 2-1. Descriptive statistical and trend tables of field and analytical data are presented in Appendix C for the Shallow and Deep Aquifers. The Post Slurry Wall Construction Long Term Trend Data is filtered by season (winter/summer) in order to be more representative of the entire time period (April 1989 to September 2018). Graphical representations of parameters with exceedances and/or visual trends are presented in Appendices D and E as time concentration plots. Two plots are constructed for each parameter: one for the period of record and a second covering the past five years of data. Groundwater environmental monitoring data are tabulated in Appendix F.

The results are used collectively to indicate the characteristics of the groundwater. Corroboration by several indicators is necessary before impacts from waste in-place can be considered a reasonable conclusion.

2.3.3 SHALLOW AQUIFER MONITORING WELL RESULTS

Quarterly groundwater monitoring has been performed by KCSWD in six shallow aquifer wells since 1986. Field and laboratory analysis results are discussed in this section. Numerical ranges reference the values from the last 8 data points, or from the last two years of samples. Wells are located north, south, and west of the Landfill (Figure 2).

MW-11 (Upgradient/Background Well)

MW-11 is located near the northeast corner of the site. It is also located near the Ditch, which may have been a source of recharge to the Shallow Aquifer prior to 2009. This well serves as an upgradient monitoring well for the Shallow Aquifer (see Figure 2).

Data collected from MW-11 indicate that slightly acidic conditions of 5.77 to 6.57 pH units prevail with regular exceedances of the field pH lower standard limit. Specific conductance, total dissolved solids, alkalinity, chloride, sulfate, nitrate, ammonia, iron, and manganese are low and relatively stable. The minimum, maximum, and mean for these parameters over the last eight sampling events are available in Table 2-2. Chloride has been found to have increasing short and long term trends at MW-11.

MW-11 remains a representative groundwater quality monitoring well upgradient of the Landfill.

MW-1, MW-4, MW-6, MW-10, & MW-18 (Side and Downgradient Wells)

MW-6 is located in the southeast corner of the Landfill and is hydraulically side gradient to the Landfill. MW-1 is located near the southern boundary of the Landfill. MW-10 is located southwest of the Landfill, while MW-18 and MW-4 are located west of the Landfill (see Figure 2). Piezometric head data indicate these last four wells are hydraulically downgradient of the Landfill. Groundwater in these five wells tends to be slightly acidic to neutral with pH mean values range between 6.0 and 6.9 pH units. Chloride concentrations have been decreasing over time after the Slurry Wall installation. However, recent increasing long term trends at MW-1 and short term at MW-6 for chloride have been detected. These detections are consistent with an increasing trend at MW-11 (upgradient monitoring well). Chloride concentrations for MW-6 are similar to those found at MW-11.

Sample results from wells MW-1, MW-10 and MW-18 generally exhibit either statistically significant long term decreasing trends, or no trend for all parameters with an exception of chloride at MW-1. Sample results from wells MW-4 and MW-6 generally have fewer statistically significant long term decreasing trends (versus no trend found), with only increasing long term trends found for magnesium from MW-4, and chloride and nitrate from MW-6.

Sample results from MW-4 had an increasing short term trend for a few parameters including calcium, magnesium, sodium, and pH (Appendix C). Samples from the Shallow Aquifer down and side gradient wells have similar nitrate concentrations to the upgradient well, MW-11.

Field pH was reported below the lower limit for the WSGWQS secondary criteria in all wells for at least one field sampling event the past year. Arsenic detections are exceeded the WSGWQS primary criteria in all samples analyzed after adoption of the LLOQ methodology except MW-4 where it remains undetected. Iron exceedances for secondary standards were reported for all sample results from MW-10 and three out of four sample results from MW-1. Manganese exceeded WSGWQS secondary criteria in all samples collected from MW-1, MW-3, and MW-10. Iron, manganese, and arsenic all occur naturally in groundwater of this region and therefore are believed to be representative of groundwater quality unaffected by Hobart Closed Landfill. Moreover, natural background of arsenic concentration in groundwater for Puget Sound Basin, Washington State is 0.008 mg/L (*Natural Background Groundwater Arsenic Concentrations in Washington State*, 2016). No other water quality criteria were exceeded during this period.

VOCs were rarely reported in shallow wells. Chloroform was detected at MW-1, 10, 11, and 4 in the 4th quarter of 2019. Recent changes to lower reporting limits resulted in quantifiable results for 1,1,1-trichloroethane and 1,1-dichloroethane in samples collected from MW-6 in the 4th quarter of 2019. However, all these results were qualified as estimated (“JT” qualified) by the contract lab due to being reported below the LLOQ.

In general, groundwater sample results from MW-1, MW-6 and MW-10 have relatively higher levels of specific conductance, total dissolved solids, alkalinity, calcium, potassium, and manganese when compared to upgradient groundwater. MW-4 and MW-18 parameter concentrations have declined and stabilized at levels similar to those upgradient for most parameters. The minimum, maximum, and mean for these parameters over the last eight sampling events are listed in Table 2-2. Short term, there are few statistically significant decreasing trends for these wells. In general, the limited number of statistically significant long term increasing trends versus decreasing or no trend found indicates water quality is stable or improving in the Shallow Aquifer.

2.3.4 DEEP AQUIFER MONITORING WELL RESULTS

Quarterly groundwater monitoring has been performed by KCSWD in three deep aquifer wells since 1986. Field and laboratory analysis results are discussed in this section. Numerical ranges reference the values from the last 8 data points, or from the last two years of samples. Wells are located north, south, and west of the Landfill (Figure 2).

MW-25 (Upgradient/Background Well)

MW-25 is located north of the Landfill and based on piezometric head data, is hydraulically upgradient of the Landfill. This well was installed in 2001 to replace MW-9, which was damaged in the 2001 Nisqually earthquake. The conditions found in MW-25 are considered representative of background water quality in the Deep Aquifer.

Groundwater sample results from MW-25 was reported as slightly alkaline. Alkalinity, chloride, sulfate, and iron (non-detects of iron in samples) levels are low and stable. The minimum, maximum, and mean for reported sample results are consistent with historical values. The sample results demonstrated stable short term trends for these parameters over the last eight sampling events and are available in Table 2-2. Long term sample results show a mix of increasing and decreasing trends for conventional and metal parameters which is corresponding with the previous years' history.

As an upgradient well, samples from MW-25 exceeded the WSGWQS criteria for arsenic in all four recent samples.

Dichlorodifluoromethane was detected in all four samples in MW-25 but did not exceed WSGWQS or Federal Drinking Water criteria. There were no other volatile organic compounds detected in MW-25 during this period.

MW-7 & MW-3 (Downgradient Wells)

MW-7 is located south of the Landfill, and MW-3 is located west of the Landfill. Based on piezometric head data, these two wells are hydraulically down gradient of the Landfill.

Groundwater samples from MW-7 and MW-3 reported as slightly alkaline, with mean alkalinities of 129.6 and 70 mg/L, respectively. Specific conductance, total dissolved solids, alkalinity, sulfate, calcium, magnesium, potassium and sodium levels in MW-7 and MW-3 were higher than those in upgradient well MW-25. In addition, sample results from MW-3 had higher concentrations of manganese. The minimum, maximum, and mean for these parameters over the last eight sampling events are available in Table 2-2.

There were no statistically significant short term trends (increasing or decreasing) from MW-3 and MW-7, except for increasing chloride and pH for MW-3. Both monitoring points however have a mix of long term increasing and decreasing trends.

MW-7 demonstrated long term either decreasing or unchanged trends for metals and conventionals, with the exception of pH that increased. MW-3 showed long term increasing trends for specific conductance, alkalinity, chloride, sulfate, total dissolved solids, and five metals (calcium, magnesium, manganese, potassium, and sodium), all of which are major iconic species. All of these parameters met regulatory criteria except for manganese that only exceeded secondary standards. Monitoring will continue to assess any future changes to groundwater quality characteristics.

Recent changes to lower reporting limits resulted in quantifiable results for chloroform and dichlorodifluoromethane in MW-3. Declining concentrations had been tracked from 1992 through 2008 with a 0.2 µg/L reporting limit. MW-3 sample result for chloroform was quantified at 0.12 µg/L, just above the detection limit (non-detect samples are below 0.1 µg/L). Dichlorodifluoromethane sample results from MW-3 in three out of four samples were qualified between 0.116 and 0.153 µg/L respectively (non-detect samples are below 0.1 µg/L). These results were qualified as estimated ("JT" qualified) by the contract lab due to being reported below the LLOQ. No other volatile organic compounds were detected in MW-3 or MW-7.

Arsenic was detected in all four MW-3 and MW-7 samples for the past year. These recent detections are attributed to the adoption of the LLOQ methodology that established a detection limit of 5E-05 mg/L. Detections are implicitly exceedances of the primary WSGWQS criteria; however, results are also below with the natural background concentrations for groundwater Puget Sound Basin in the State of Washington (*Natural Background Groundwater Arsenic Concentrations in Washington State*, 2016).

2.3.5 SLURRY WALL PERFORMANCE

The slurry wall containment continues to isolate the Shallow Aquifer beneath the Landfill from the local groundwater flow system. Pumping wells installed beneath the solid waste and inside the Slurry Wall have historically lowered the groundwater table below the base of refuse. The water elevation outside of the Slurry Wall has remained consistently above the water elevation inside (see Figure 5). As a result, an inward hydraulic gradient has been created resulting in a system which reduces the possibility of breakthrough of contaminants and off-site transport.

Concurrent with the construction of the Slurry Wall, the northern half of the Landfill was closed with an HDPE final cover. The southern half was later closed also with an HDPE final cover in 1994. Consequently, local recharge to the aquifer was reduced.

Six indicators have been used to evaluate the slurry wall performance: chloride, arsenic, manganese, 1,1-Dichloroethane, 1,1,1-Trichloroethane, and *cis*-1,2-Dichloroethene. Chloride is an early indicator of leachate, and manganese is sensitive to redox conditions. Their movement through groundwater is controlled by different chemical processes. Chloride migration is not retarded by such processes as adsorption, cation exchange, biological uptake or redox processes. The distribution of manganese, however, is strongly controlled by redox processes. Reducing conditions permit manganese to dissolve and be transported in groundwater. A reducing condition prevails when oxygen is depleted by waste degradation and sustained by the presence of BOD and anaerobic metabolism. Thus, manganese may be an indicator of landfill impacts.

Chloride in all of the down and side gradient wells has been reduced to levels found in MW-11 (background). Manganese levels have been reduced in all wells but remain elevated relative to MW-11 in MW-1, MW-10 and MW-18.

Until the analytical laboratory change, arsenic had only been detected consistently in one Shallow Aquifer well, MW-10, and one Deep Aquifer well, MW-25. Recent detections in all wells (except MW-4) are due to the switch to LLOQ reporting methodology. For both MW-10 and MW-25, arsenic concentrations have been consistently decreasing over time.

Organic compounds have been detected with relatively low frequency and at low level both prior to and since construction of the Slurry Wall. The concentration levels for *cis*-1,2-dichloroethene, 1,1-dichloroethane, and 1,1,1-trichloroethane have been used to evaluate the success of remediation indicated by their decrease over time. There have been no significant changes in sample detections of these compounds in any shallow wells since 2008 with an exception described in Section 2.3.3. In the 4th quarter of 2019, MW-6 sample results for one time reported of 1,1,1-trichloroethane and 1,1-dichloroethane were quantified at 0.114 JT and 0.104 JT µg/L

correspondently, just slightly above the new detection limit (non-detect samples are below 0.1 µg/L). However, all these results were qualified as estimated (“JT” or “BJT” qualified) by the contract lab due to being reported below the LLOQ.

A summary of the performance of the Slurry Wall and drawdown wells showing water quality prior to containment and after containment is presented in Table 2-3.

This water quality evaluation, in conjunction with water level data shown in the potentiometric mapping and the trend analyses, demonstrates that the Slurry Wall is functioning as designed: maintaining groundwater elevation separation below the waste by preventing groundwater migration inside the wall perimeter. Elevated groundwater levels below waste are attributed to increased cover infiltration due to higher precipitation levels since 2009.

CHAPTER 3: LANDFILL GAS

Landfill gas is monitored by a network of compliance probes installed around the perimeter of the Landfill and ambient air stations around the property boundary. Landfill gas compliance probes are monitored monthly. Landfill gas ambient stations are monitored quarterly. The landfill gas probes and ambient stations monitoring results can be found in Appendix G. There were no methane detections in the period of October 2019 through September 2020. Gas probe monitoring data are provided in Appendix G and their locations are shown in Figure 3.

In 2019, the landfill gas probe GP-7 was decommissioned by over-drilling using hollow-stem auger methods. A new gas probe, GP-9, was installed as a replacement for GP-7. Additional details for decommissioning and installation of GP-7 and GP-9 can be found in *Landfill Gas Probe Installation and Decommissioning Technical Memorandum*, (Aspect Consulting, 2019).

CHAPTER 4: SUMMARY AND CONCLUSIONS

The conclusions of this groundwater quality evaluation report are presented according to aquifer and time period.

4.1 SHALLOW AQUIFER

The Shallow Perched Aquifer is an unconfined water table aquifer that has historically saturated lower portions of the solid waste beneath certain areas of the Landfill. Since completion of the Slurry Wall remediation construction in 1989, the shallow water table has been contained from coming into contact with refuse, and the groundwater gradient around the Landfill has been altered to minimize off-site transport from beneath the Landfill.

Information presented in this report suggests that on-site monitoring wells installed in the Shallow Aquifer and located hydraulically downgradient of the Landfill may have historically been influenced by landfilling activities. When monitoring began in 1986, the downgradient wells had elevated levels of some leachate indicator constituents with respect to the upgradient wells. Since 1986, these constituents have become progressively less concentrated in downgradient wells, as a result of improved landfill site conditions and Shallow Aquifer containment activities, particularly installation of the low permeability bentonite Slurry Wall.

Wells in the Shallow Aquifer displaying historic impacts from landfilling activities consisted of MW-1, MW-4, MW-6, and to a lesser extent, MW-10 and MW-18. These wells are located along the west and south perimeter of the landfill. Concentrations were highest prior to completion of the Slurry Wall. Trend analyses show that statistically significant decreases in long term trends of indicator parameters have occurred in the side and down gradient wells. Recent short term trend analysis indicates increasing trends for pH in MW-4, and chloride in MW-6 and MW-11 (upgradient).

In general, water quality in this aquifer has improved and demonstrates stability in current conditions.

VOCs associated with Shallow Aquifer detections prior to and in the early Slurry Wall phase have decreased with only three estimated volatile detections reported since December of 2008, excluding suspected analytical laboratory contaminant volatile results. Recent detections are attributed to lower detection limits (below previous reporting limits), which further confirms that concentrations have declined and are detectable only infrequently.

Current water quality conditions in the Shallow Aquifer continue to approach background constituent concentrations and no future increases in contaminant levels are expected given current site wide trends.

4.2 DEEP AQUIFER

The refuse is located in excess of 100 feet above the Deep Aquifer and is separated from the deeper water bearing zone by about 80 feet of dry or moist soils. A low permeability (10^{-6} cm/sec) perching layer of the OUD is continuous beneath the Landfill and separates the two hydrogeologic systems. The lack of moisture in the soils indicates that hydraulic connection between the fill and

the groundwater is not strong and the soil capacity to retard contaminants is enhanced because of unsaturated conditions.

General geochemistry parameters at MW-7 are elevated relative to the upgradient well, but all have shown relatively stable concentrations over both the long term and short term periods. In addition, the concentrations of these parameters are below both Federal Drinking Water and WSGWQS exceedance criteria. The frequency of VOC detections in the Deep Aquifer has decreased considerably over time, with only dichlorodifluoromethane detected regularly in MW-25, an upgradient well, and 1,1-dichloroethane having recent detection in MW-7 due to the change in laboratory detection limit methodology. Both of these detections are below the WSGWQS criteria.

Long term, ionic species analytes (e.g. conductivity, sodium, chloride, etc.) have shown increasing trends at both upgradient well MW-25, and downgradient MW-3, over time. This may indicate that an off-site, upgradient source is impacting the Deep Aquifer water quality beneath the Landfill.

In general, the groundwater quality in the deep aquifer has improved over time.

4.3 RECOMMENDATIONS

Recommendations for the next year for Hobart Closed Landfill are:

- Maintain engineered controls, including the engineered cover, the leachate extraction system, landfill gas treatment system, and the stormwater management structures.
- Continue monitoring water level, field parameters and groundwater sampling on a quarterly basis at all wells in the current monitoring network, and landfill gas compliance probe monitoring on a monthly basis.
- Continue evaluating the engineering control systems: landfill cover, containment wall, leachate extraction system, landfill gas collection and treatment system, and stormwater management structures to determine whether modifications are needed to meet regulatory and operational criteria.
- Perform appropriate pumping needed to maintain hydraulic gradients and waste isolation.
- Evaluate the groundwater monitoring program in 2021 to determine whether modifications to frequency and parameters are indicated.

TECHNICAL MEMORANDUM

November 12, 2020

TO: Natalya Usova, Engineer II, Facility Engineering and Science Section, Solid Waste Division, Department of Natural Resources and Parks (DNRP)

FM: Sevin Bilir, Environmental Scientist IV, Science and Technical Support Section, Water and Land Resources Division, DNRP

RE: Potentiometric Groundwater Surface Maps & Groundwater Velocity Calculations Water Year 2019-2020 Results
Hobart Closed Landfill, King County, Washington
Project No. 1033596 – Task 23.14.137.44

The King County Water and Land Resources Division (KCWLRD) submits this during the 2019-2020 water year for the shallow and deep aquifers beneath the Hobart Closed Landfill (Landfill), in accordance with the *Proposal for 2020 Potentiometric Groundwater Surface Maps & Groundwater Velocity Calculations* (KCWLRD, 2020). King County Solid Waste Division (KCSWD) personnel measured depth to water at the Landfill quarterly during the 2019-2020 water year.

These measurements were received by KCWLRD on September 18, 2020 and were used to:

1. Evaluate the potentiometric groundwater surface during the quarters with the lowest and highest water levels for the shallow and deep aquifers;
2. Determine the groundwater flow direction and horizontal gradient during the quarters with the lowest and highest water levels for the shallow and deep aquifers; and
3. Calculate the groundwater flow velocities during the quarters with the lowest and highest water levels for the shallow and deep aquifers.

The KCSWD resurveyed all monitoring well locations and elevations to new datums in 2019 and the new data are reported in tables in this document.

There have been no significant changes in the groundwater flow direction for both the shallow and deep aquifers during the 2019-2020 water year since the previous report submitted for the 2018-2019 water year monitoring event. Due to a more recent assessment of aquifer parameters, the calculated velocity for the deep aquifer is greater than in previous reports.

Groundwater Elevation Data

The KCSWD attempted measurements of groundwater levels quarterly during the 2019-2020 water year at 14 monitoring wells completed in the shallow or deep aquifers. Groundwater level measurements were also attempted in nine wells located inside the slurry wall surrounding the landfill. The highest groundwater elevations were measured during the second quarter monitoring event performed on February 24, 2020. The lowest groundwater elevations were measured during the fourth quarter monitoring event performed on August 13, 2020. Only data from these events are presented in this report.

Table B-1 list groundwater monitoring well identifications, locations, well construction details, measured depth to groundwater levels and calculated groundwater elevations for monitoring wells screened in the shallow and deep aquifers, as well as for the water-bearing zone located inside the slurry wall.

Shallow Aquifer and Inside Slurry Wall

Figures B-1 and B-2 show calculated groundwater elevations at well locations screened in the shallow aquifer for the quarters with the highest and lowest water levels during the 2019-2020 water year, respectively. A limited representation of inferred groundwater potentiometric surface contours were mapped in the shallow aquifer during the 2019-2020 water year. The range of the groundwater levels (less than a foot difference for many wells) did not allow for a representative groundwater potentiometric surface contour to be drawn over the entire landfill.

Groundwater elevations for monitoring wells in the shallow aquifer were on average 5.8 and 3.5 feet (ft) higher for the highest and lowest water level time periods, respectively, than those measured in the previous water year. Groundwater levels in the highest water level time period were on average 5.8 ft higher than those in the lowest water level time period. During both events, monitoring well LP-7 located inside the slurry wall was reported as dry.

During the highest and lowest water level time periods, water levels measured inside the slurry wall were on average 8.3 and 3.7 ft below groundwater levels outside the wall, respectively. This difference indicates hydraulic separation from the shallow aquifer and is

similar to those calculated in previous water years. Groundwater levels inside the slurry wall were on average 3.7 and 3.1 ft higher, respectively, than those measured for the highest and lowest water level time periods in the previous water year.

Deep Aquifer

Figures B-3 and B-4 show calculated groundwater elevations at well locations (MW-3, MW-7 and MW-25) screened in the deep aquifer for the quarters with the highest and lowest water levels during the 2019-2020 water year, respectively.

Groundwater elevations wells screened in the deep aquifer were on average 6.1 and 3.9 ft higher during the highest and lowest water level time periods, respectively, than those measured in the previous water year. Water levels in the highest water level time period were on average 3.5 ft higher than those in the lowest water level time period.

Direction of Groundwater Flow

Figures B-1 through B-4 show interpreted groundwater flow directions where possible, in the shallow and the deep aquifers, for the time periods reflecting the highest and lowest groundwater level elevations, based on the measurements made in February and August of 2020. Table B-2 also reports the flow directions based on measurements and mapping of groundwater elevation contours.

Figure B-1 shows interpreted groundwater flow directions in the shallow aquifer where possible, for the highest water levels during the 2019-2020 water year. Groundwater elevations indicate that groundwater generally flowed towards the west around the slurry wall in the shallow aquifer. Limited interpretation is shown on Figure B-2 for the shallow aquifer during the period with lower water levels. Based on historical knowledge of flow direction in the shallow aquifer and the groundwater elevations at the wells shown in Figure B-2, flow direction arrows are shown to indicate that groundwater generally flowed towards the west around the slurry wall.

The groundwater elevation at MW-16 was higher than elevations observed at the nearest shallow aquifer wells by about 2.5 to 5.6 feet. This may be caused by groundwater mounding upgradient of the landfill as groundwater approaches the slurry wall and flows around the north and south sides of the slurry wall.

Figures B-3 and B-4 show groundwater potentiometric surface contours and interpreted groundwater flow directions in the deep aquifer, based on the 2019-2020 water year quarterly measurements. Groundwater elevations indicate that groundwater generally flowed west to west-southwest during quarters with the lowest and highest water levels in the deep aquifer during the 2019-2020 water year.

Groundwater Parameters

Horizontal groundwater velocity was calculated using the following formula:

$$\text{where: } v = \frac{I}{n_{eff}} K \frac{\Delta H}{\Delta L}$$

$$\begin{aligned} v &= \text{Groundwater velocity [L/t]} \\ n_{eff} &= \text{Effective porosity [dimensionless]} \\ K &= \text{Hydraulic conductivity [L/t]} \\ \frac{\Delta H}{\Delta L} &= \text{Hydraulic gradient [L/L]} \end{aligned}$$

Table B-2 presents a summary of the groundwater parameters. The hydraulic conductivity and effective porosity values were based on the data referred to in *Phase 1 –Groundwater Flow Model Construction and Calibration Report: Hobart Closed Landfill* (Aspect, 2020). The geometric mean of horizontal hydraulic conductivity was reported to be 1423.93 feet per day (ft/d) in the shallow aquifer, and 2.35 ft/d in the deep aquifer (Aspect, 2020). The porosity was reported as 30 percent in both aquifers based on values estimated from values reported for similar hydrogeologic units (Aspect, 2020).

The hydraulic gradient was determined from the potentiometric surface maps, where possible (Figures B-1 through B-4). The hydraulic gradient in the shallow aquifer was calculated using groundwater elevations measured in wells along the northwest and south side of the slurry wall, where and when possible. The gradient in the deep aquifer was calculated using the three wells measured during the 2019-2020 water year.

Table B-2 presents a summary of the groundwater parameters used to calculate a groundwater velocity for both aquifers. The velocity calculated for the shallow aquifer was 15 ft/day for the highest quarter. The data for the lowest quarter did not allow for calculation of velocity. The velocities calculated for the deep aquifer were 0.24 and 0.25 ft/day for the highest and lowest quarters, respectively. The velocity calculated for the shallow aquifer was within the range of groundwater velocities calculated during the 2018-2019 water year. Due to the change in the value used for hydraulic conductivity of the deep aquifer, the velocity calculated for the deep aquifer was much higher than reported in previous years.

Notes:

1. Water level measurements made by KCSWD personnel.
2. Reference datum is different than in previous reports. Current easting and northing coordinates are based on Washington State Plane Coordinate System, North Zone (NAD 83/11). Survey data for easting and northing coordinates were collected on September - October 2019
3. Lowest groundwater levels reflect water year minimum groundwater elevations, measured on February 24, 2020.
4. Highest groundwater levels reflect water year maximum groundwater elevations, measured on August 13, 2020.
5. Wells recently installed in 2016 for added characterization and added to report for mapping potentiometric surface.
6. Wells recently installed inside slurry walls in 2016 for added characterization and added to report for mapping potentiometric surface.
7. Elevations reported in feet (ft) above mean sea level (MSL) based on the North American Vertical Datum of 1988 (NAVD 88). Survey data for elevations were collected during September - October 2019

D = Decreasing concentrations
 I = Increasing concentrations
 -- = There is no trend.
 Probability = probability that the null hypothesis (Ho) is true.
 Significant = The trend is significant at a p = 0.05 level.

NOTES: Long - Period of Record excluding the last 8 sampling quarters. Short - Results from the 8 most recent sampling quarters. * Gradient indicates location of monitoring well relative to the hydraulic gradient and the placement of Solid Waste.																		

D = Decreasing concentrations
I = Increasing concentrations
-- = There is no trend.
Probability = probability that the null hypothesis (Ho) is true.
Significant = The trend is significant at a p = 0.05 level.

APPENDIX F

Hobart Closed Landfill Groundwater Monitoring Data

KING COUNTY SOLID WASTE DIVISION
QUALIFIER INFORMATION
(Effective 8/27/2015)

QUAL	QUALIFIER DESCRIPTION
U	Undetected; Analyte Concentration Less than Method Detection Limit (< MDL)
T	Estimated; Less than Reporting Detection Limit (<RDL) but Greater than Method Detection Limit (> MDL)
J	Reported Value is an Estimate
B	Matrix Target Analyte Present in Blank, AND, Sample Result Less than or Equal to 10x Blank Detection
C	Confluent Growth
E	Estimated; Outside Expected Accuracy
H	Exceeds Holding Time
R	Data Rejected
S	Sample Handling Errors
X	Too Numerous to Count
D	Re-analysis Due to Dilution
P	PASS – Qualitative Result Acceptable
F	FAIL – Qualitative Result is not Acceptable
G	Estimated with Low Bias (Coliform; BOD; All Other Chemistry Parameters)
L	Estimated with High Bias (BOD; All Other Chemistry Parameters)
