RE: Hobart Closed Landfill 2022 Annual Groundwater Data Evaluation Report

The purpose of this memorandum is to transmit a copy of the Solid Waste Division's *Hobart Closed Landfill 2022 Annual Groundwater Data Evaluation Report* for your review. This report includes an executive summary, site specific summary, exceedances table, trend test table, recommendations, potentiometric surface maps (p-maps), time-concentration plots of parameters of interest, and field and lab data in PDF format. The groundwater quality discussion is focused on exceedances, trend table, graphs, and p-maps.

We will continue to provide these reports on groundwater data evaluation as part of the reporting requirements. We will address any revisions and concerns that you might have about this document in our next annual report. We appreciate your comments to improve these reports.

If you have any questions regarding this report, please contact me at me at (206) 263-0608, or via email at [nusova@kingcounty.gov](mailto:nusova@kingcounty.gov).

**2022 Annual Groundwater Data Evaluation Report Certification**

I certify in accordance with the requirements of Chapter 18.220 RCW, that the contents of this Groundwater Data Evaluation Report were prepared under my direction under a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Where applicable, some specific and related hydrogeologic portions have been duly certified by the responsible geologist or engineering geologists in accordance with Chapter 18.220.010 (12) RCW. Based on my inquiry of the person(s) directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete.

## EXECUTIVE SUMMARY

---

This annual report presents the Hobart Closed Landfill (Landfill) evaluation of groundwater quality and water level data collected from October 1986 through September 2022.

Groundwater investigations in the mid-1980s led to remediation design and installation of a bentonite Slurry Wall to isolate the shallow groundwater beneath the refuse from the aquifer present below the Landfill. The groundwater beneath the Landfill was pumped out and a lower water level inside the Slurry Wall has been maintained since 1989. Final closure of the north half of the Landfill was completed in 1990 and of the south half in 1994, with the placement of a high density polyethylene (HDPE) cap, drainage layer, and vegetative layer over the refuse. From final closure until recently, pumping had not been required to maintain water levels below refuse and an inward gradient across the Slurry Wall.

Groundwater quality and water level data are collected quarterly and reviewed to summarize and evaluate groundwater quality at the Landfill and determine changes, if any. Water quality data includes samples collected from ten monitoring wells.

Groundwater flow beneath the Landfill has been evaluated by a licensed hydrogeologist. The report is included as Appendix B. The groundwater beneath the Landfill occurs in two aquifers: the Shallow Aquifer and the Deep Aquifer. In both zones, the water generally flows in a westerly direction.

During the current evaluation period, groundwater in both aquifers shows continued improvements in water quality characteristics when compared with pre-Slurry Wall installation groundwater quality. The demonstrated water quality improvements together with the maintained head differential across the Slurry Wall provide indications that the system is continuing to function as designed. Monitoring at the Landfill will continue throughout the required post-closure period.

The water levels inside and outside the Slurry Wall are monitored quarterly. These data are used to evaluate whether the water levels within the Slurry Wall remain below the base of waste, and that the water levels inside are sufficiently below those outside the Slurry Wall to maintain an inward hydraulic gradient and minimize the potential for migration of contaminants. Since approximately 2009, seasonal high-water levels within the Slurry Wall have successively increased due to higher than historical rates of rainfall, increasing the infiltration through the cover. In 2014, an evaluation of cover integrity at geomembrane penetrations was conducted and repairs were made in three locations in early 2015.

Continued investigative efforts are underway to evaluate the environmental control systems. A contingency plan to pump and haul water to treatment was activated in 2017. This action helps maintain hydraulic gradients and waste isolation. An evaluation of the containment system (i.e., landfill cover, groundwater, landfill gas control and treatment, and landfill gas monitoring network) is being performed. King County Solid Waste Division continues evaluation of environmental control systems at the Landfill. These evaluations will determine if modifications are needed to achieve termination of post-closure status for the closed landfill. The most recent results of an evaluation of supplemental engineering control alternatives presented in a technical memorandum, *Supplemental Leachate Control Alternatives Evaluation* (Aspect 2020).

## **PURPOSE**

---

The purpose of this report is to provide an annual update on groundwater quality and water level data collected at the Landfill in accordance with WAC 173-304-405 (4)(d). The focus will be on the data collected during the last hydrologic year, from October 2021 through September 2022. Historical data will be used as a comparison and to provide context for these results. Based on this analysis, further recommendations will be made as to how to continue to monitor the groundwater quality at the Landfill.

# CHAPTER 1: LANDFILL OVERVIEW

---

## 1.1. OBJECTIVES

The objectives of this groundwater quality evaluation report for the Landfill are as follows:

- Review groundwater quality data from September 1986 through September 2022.
- Perform statistical analyses to evaluate any water quality trends, and to compare water quality between monitoring wells.
- Compare water quality data with water quality standards. Document any exceedances of Washington State Groundwater Quality Standards criteria.
- Determine whether any exceedances or trends as described above can be attributed to the Landfill.

## 1.2. SITE DESCRIPTION

The Landfill is located on 276th Street Southeast, between the towns of Hobart and Ravensdale, about 25 miles southeast of Seattle (Figure 1). The Landfill is owned by King County. It was operated and is maintained by King County Solid Waste Division (KCSWD). It occupies approximately 75 acres, of which about 35 acres have been used for refuse disposal.

Prior to the early 1950s, the Landfill site was utilized as a sand and gravel pit. Landfilling activities began in the 1950s, with refuse being placed in the former sand and gravel pit. Open burning of refuse occurred until the early 1960s. From the early 1960s to 1990, refuse was placed in a controlled manner, utilizing compaction and daily cover.

A landfill site characterization in August 1983 included installation and sampling of four groundwater monitoring wells and characterization of surficial soils. Expanded site characterizations were performed between August 1985 and March 1986 and included an additional three wells installed in solid waste, and 22 wells installed in native soils surrounding the Landfill. Quarterly groundwater monitoring is currently performed in ten wells, of which seven are in the Shallow Aquifer and three are in the Deep Aquifer (Table 1-1). The Landfill site map (Figure 2) shows the monitoring well locations.

Water quality impacts to the Shallow Aquifer were detected on site, triggering remedial activities in the Shallow Aquifer. Site remediation occurred during 1988 and 1989, including construction of a low permeability soil and bentonite slurry cutoff wall (Slurry Wall) around the Landfill. Site remediation is further described in Section 1.2.2.

In 1990, an HDPE final cover with a gas collection system was installed over 14 acres of the solid waste at the northern half of the Landfill (Phase 1 closure). In 1994, the remaining southern portion of the Landfill was closed under the Phase 2 closure project. This included: construction of a final cover and landfill gas (LFG) collection field over the south half of the Landfill; modifications and repairs to the existing LFG flare system; and, utilization of existing infiltration basins for stormwater runoff.

### 1.2.1. GEOLOGY AND HYDROGEOLOGY

The Landfill site characterization, including history, hydrogeology, and details regarding the Slurry Wall, has been documented in the reports listed in the References section. This section presents a summary of these reports' findings.

The Landfill is located within the Puget Sound lowlands of Western Washington. Geologic studies of the Landfill have identified four lithologic units at the site. These units are recessional outwash, glacial till, advance outwash, and older undifferentiated deposits (OUD). Figure 4 (Harding, 1992) is a north-south cross section depicting the occurrence and variations in thickness of these units at the Landfill.

Two aquifers have been identified beneath the site: a local or Shallow Aquifer in the recessional and advance outwash deposits, and a regional or Deep Aquifer in the pre-Vashon deposits. Beneficial use of groundwater in the vicinity of the Landfill is limited to domestic wells withdrawing from the Deep Aquifer.

**Shallow Aquifer:** The Shallow Aquifer occurs continuously below the Landfill site in recessional and advance outwash deposits. The aquifer is perched and unconfined, ranges from 5 to 36 feet below ground surface and is between 35 and 50 feet thick. The perching layer is the highly oxidized, low hydraulic conductivity upper surface of the OUD. Below the highly oxidized upper surface of the OUD, unsaturated conditions occur for over 70 feet before the Deep Aquifer is encountered. There are currently 11 monitoring wells installed in the Shallow Aquifer, seven of which are monitored on a quarterly basis (MW-1, 4, 6, 10, 11, 18, and 26). The seven wells were selected for representativeness and location. Additional wells (MW-16, 21, 22, and 27) are used to measure water levels only. The results of monitoring events are included in Table 2-1 and Appendix F.

**Deep Aquifer:** The Deep Aquifer occurs between 130 and 150 feet below ground surface (average groundwater elevation of 510-feet mean sea level). The aquifer occurs in the pre-Vashon sand and gravel deposits and appears to be unconfined. There are currently three monitoring wells installed in the Deep Aquifer, one up-gradient (MW-25), and two down-gradient (MW-3 and MW-7). MW-9 was also installed in the Deep Aquifer but was decommissioned in 2001 after it was damaged in the Nisqually earthquake. MW-25 was installed at that time to provide upgradient monitoring. The Deep Aquifer is believed to discharge to the Cedar River located southwest of the site.

### 1.2.2. SITE REMEDIATION

In 1989, a low permeability bentonite Slurry Wall was installed around the refuse and keyed into the Shallow Aquifer perching unit. Three extraction wells were installed in the Shallow Aquifer beneath the refuse. Groundwater extraction commenced from the Shallow Aquifer within the Slurry Wall to reduce hydraulic heads sufficiently below water levels outside the Slurry Wall to maintain an inward hydraulic gradient. This maintains the water table surface below the level of deposited waste and an inward hydraulic gradient around the Landfill, minimizing the potential for migration of contaminants.

### 1.2.3. GROUNDWATER AND SLURRY WALL WATER LEVELS

After the 1994 Final Closure of the Landfill, infiltration through refuse was sufficiently reduced such that extraction was no longer necessary. Water levels on the interior of the Slurry Wall were monitored monthly together with four selected monitoring wells outside of the Slurry Wall. A comparison of these water levels monthly provided verification that water levels inside the Slurry Wall remain well below outside levels, confirming the Slurry Wall and cover were functioning properly.

After noticing changes in water levels, KCSWD initiated an investigation and evaluation. In 2009, AMEC Geomatrix evaluated the conditions and effectiveness of the Slurry Wall and groundwater control system. It was determined that the piezometers and monitoring well network provided sufficient and valid water level information. Further, in the event water elevations within the Slurry Wall would begin to rise, pumping capacity was deemed adequate to counter a (0.5) foot/year rise thus maintaining hydraulic head differences and inward gradients. The evaluation also verified the continued suitability of the water level control system.

In 2014, KCSWD undertook an evaluation to determine what may be contributing to higher water levels measured within the Slurry Wall. Evaluation of cover penetrations at gas wells, piezometers and extraction wells were prioritized along with buried LFG laterals, headers, and condensate drops. This evaluation found minor tears in the cover due to settlement in three of 26 excavated cover penetrations. The repairs were completed in February 2015, and assessment concluded that the amount of infiltration through these failures would have no visible effect on water levels inside the Slurry Wall.

In 2015, KCSWD initiated further investigation and evaluation of environmental control systems at the Landfill. A technical memorandum, *Landfill Cover, Slurry Containment Wall, and Leachate Management Alternatives Technical Memorandum* (Aspect 2015) was prepared and concluded that the cover was performing to design specifications, but recent precipitation had exceeded the historical average. Six alternatives were identified to address rising groundwater levels beneath waste with work continuing to assess the feasibility of implementation. As a part of this project, six piezometers were installed, four within the Slurry Wall and two outside. Additionally, gauging stations were installed on conveyances carrying stormwater to infiltration basins onsite. Water levels and flow were monitored using a network of transducers to better define flow and recharge dynamics. The initial water balance study was completed, and the results documented in the *Landfill Cover Water Balance Technical Memorandum* in December 2017. A follow-up confirmation water balance study was completed in 2019 with findings confirmed in 2019.

In 2017, analysis of water level data noted that the minimum difference in hydraulic head between the inside of the Slurry Wall and outside had lessened and contingency pumping was initiated in June of 2017. Approximately 800,000 gallons of water were removed from within the Slurry Wall containment. Pumping activities have been effective to maintain the inward hydraulic gradient and separation between groundwater and the base of refuse. Upgrades to leachate extraction wells were performed in 2019.

Top of casing elevations for the wells in solid waste were surveyed in March 2009. In September through October 2019, a follow-up effort to resurvey elevations in the North American Vertical

Datum of 1988 (NAVD 88) was performed with survey data being incorporated into KCSWD base maps and reports. Wells and piezometers within the Slurry Wall have been resurveyed and updated to NAVD 88, with monitoring wells outside the slurry wall. Once all elevations are updated, presentation and assessment of water levels data will be presented in NAVD 88, including Figure 5.

Figure 5 shows the historical levels of hydraulic head in monitoring wells located outside the Slurry Wall and water level measurements obtained inside the Slurry Wall.

Based on recommended steps in *Supplemental Leachate Control Alternatives Evaluation. Technical Memorandum* (Aspect 2020), in 2021, Public Health – Seattle and King County (Public Health) granted a variance for a period of three years from the requirements for groundwater extraction from the Slurry Wall. The first round of samples has been collected from the monitoring network inside of the Slurry Wall (i.e., LEW-1, LEW-4, LEW-5, LP-1, LP-3, LP-5, LP-6, and LP-8) between September 8th and 19th, 2022. Copies of a laboratory report and field sheets related to the first round of samples were submitted to Public Health and Washington State Department of Ecology via an email on November 30<sup>th</sup>, 2022.

#### **1.2.4. WALSH LAKE DIVERSION DITCH**

In the 1930s, the City of Seattle constructed the Walsh Lake Diversion Ditch (Ditch) to divert the water contaminated by the town of Taylor, Washington. The water was intercepted just above the natural confluence with Rock Creek, a tributary of the Cedar River in the Municipal Watershed, and conveyed 1.7 miles to a discharge point on the Cedar River downstream of the Landsburg Diversion Dam. The Ditch, flowing upgradient and along the north edge of the Landfill, was lined in selected areas around the same time that the Slurry Wall was constructed to reduce Shallow Aquifer recharge and thereby reduce hydraulic head in the vicinity of deposited waste.

The Ditch and adjacent slopes were prone to periodic failures due to the Ditch's problematic location in a steep ravine above Rock Creek. In a January 2009 storm event, a 300-foot section of the Ditch catastrophically failed, effectively disconnecting and dewatering the downstream section of the Ditch. Because the Ditch was no longer needed, Seattle Public Utilities did not repair it, but rather, in 2012 restored the confluence of the Walsh Lake and Rock Creek stream systems. Since this failure and restoration, there is no longer any flow in the Ditch adjacent to the Landfill.

## CHAPTER 2: GROUNDWATER DATA EVALUATION

---

### 2.1 GROUNDWATER ELEVATIONS AND FLOW DIRECTION

Groundwater levels in individual wells have been plotted as a function of time (Figures 6 and 7). Groundwater flow directions were estimated based on water elevations recorded in monitoring wells screened in similar water-bearing zones (Appendix B). Upgradient and downgradient wells are determined by flow direction.

**Shallow Aquifer:** Potentiometric groundwater surface maps, based on water levels recorded in the on-site monitoring wells, indicate a general aquifer flow to the west (Appendix B). The Slurry Wall is constructed of low permeability materials that prevent inward flow. The measured water levels for wells outside the Slurry Wall and piezometers inside are shown in Figure 5. Seasonal variation of up to six feet in water level measurements has been observed for individual wells (Figure 6).

**Deep Aquifer:** Potentiometric groundwater surface maps (Appendix B) based on the three monitoring wells indicate a westerly hydraulic flow direction, which sometimes flows southwesterly, depending on the season. A seasonal water level fluctuation up to three feet has been recorded in the three on-site monitoring wells. Water level fluctuation in these wells has lagged behind that of the shallow wells by about one month (Figure 7).

The calculated horizontal gradients across the Slurry Wall during all four quarters for four sets of paired wells has been included within this report and can be found in Appendix B.

### 2.2 DATA EVALUATION METHODS

The analyte list for routine groundwater monitoring at the Landfill was assembled from parameters listed in WAC 173-200 – *Water Quality Standards for Groundwaters of the State of Washington* (WQSGWSW), including field and conventional parameters, dissolved metals, and volatile organic compounds (VOCs). Some of these analytes are useful in characterizing groundwater quality, as indicators of impacts to groundwater from LFG and leachate, or in screening for potentially harmful effects to human health and the environment. The data evaluation focuses on these analytes.

Environmental samples are collected, analyzed, and evaluated by the procedures described in the *Environmental Monitoring Quality Assurance Project Plan and Sampling Analysis Plan for Cedar Falls, Enumclaw, and Hobart Closed Landfills* (QAPP/SAP) (KCSWD, 2015). The QAPP/SAP describes activities undertaken to ensure that analytical results meet data quality objectives (DQOs) including are representative of actual groundwater conditions. For this report, the graphical representation includes those parameters that have exceeded regulatory limits or/and have a visual trend. The water quality discussion is focused on exceedances, a trend table, graphs, and potentiometric maps.

## **2.3 GROUNDWATER CHEMISTRY RESULTS**

This section presents results and interpretation of water chemistry evaluations performed for each groundwater monitoring well at the Landfill. The results are presented according to aquifer and location relative to the principal groundwater flow direction. Discussion emphasis is on results obtained since the last annual groundwater evaluation report, which contains samples from the 4<sup>th</sup> quarter of 2021 through the 3<sup>rd</sup> quarter of 2022. Statistical comparisons have been compiled for three time periods: prior to Slurry Wall construction (October 1986 to April 1989); post Slurry Wall construction (April 1989 to 3<sup>rd</sup> quarter 2020); and the last eight sampling periods (4<sup>th</sup> quarter 2020 through 3<sup>rd</sup> quarter, 2022). King County Environmental Laboratory (KCEL) has performed laboratory services for groundwater samples collected at the Landfill. KCEL has Washington State Department of Ecology accreditation through the Washington State Manchester Environmental Laboratory for the methods and analytes used at the time that the samples were analyzed for the reporting period.

### **2.3.1 LOWER LIMIT OF QUANTITATION**

Changes made to the guidance for analytical testing methodologies covered by SW-846 (Test Methods for Evaluating Solid Waste) were implemented in 2017. One specific effect of these changes was to replace the Method Detection Limit (MDL) methodology with the Lower Limit of Quantitation (LLOQ) methodology as the basis for determining the lowest quantitative value of an analyte that can be reported. This affected all methods covered within SW-486.

The LLOQ is a performance-based methodology that tests known standards repeatedly to create a calibration curve for each specific laboratory analysis method. Commonly, the lowest concentration of the (linear) calibration curve is set as the LLOQ. However, in some cases the LLOQ may be greater than the baseline curve concentration due to lab specific factors such as instrument sensitivity and method analytical uncertainty.

During the second quarter of 2017, a transition to the LLOQ methodology occurred for metals analysis, SW846 Method 6020B, and for volatile organics, SW846 Method 8260C. This resulted in revised reporting limits for many analytes. For trace metals analytes, the quantitation limit was typically lower than the previous reporting limit. For VOCs, limits varied higher and lower (or unchanged) due to analyte specific considerations. As a result of these changes, previously undetected trace metals are now being reported as quantified, as are a few volatile compounds (1,1-dichlorethane, chloroform, dichlorodifluoromethane, and vinyl chloride) at differing wells/dates. Volatile detections are not exceedances of the WQSGWSW, and concentrations are being reported below previous reporting limits.

### **2.3.2 ANALYSIS OVERVIEW**

Water quality analysis for the Shallow and Deep Aquifers are presented in this section. In general, water quality in both aquifers has improved over time and demonstrates stability in current conditions. Exceedances of the WQSGWSW criteria that occurred during this reporting period (October 2021 through September 2022) are listed in Table 2-1. Descriptive statistical and Mann-

Kendall trend tables of field and analytical data are presented in Appendix C for the Shallow and Deep Aquifers. The post Slurry Wall construction long-term trend data are filtered by season (winter/summer) to be more representative of the entire time period (April 1989 to September 2020). Graphical representations of parameters with exceedances and/or visual trends are presented in Appendices D and E as time concentration plots. Two plots are constructed for each parameter: one for the period of record and a second covering the past five years of data. Groundwater environmental monitoring data are tabulated in Appendix F.

The results are used collectively to indicate the characteristics of the groundwater. Corroboration by several indicators is necessary before impacts from waste in-place can be considered a reasonable conclusion.

### **2.3.3 SHALLOW AQUIFER MONITORING WELL RESULTS**

Quarterly groundwater monitoring has been performed by KCSWD in six shallow aquifer wells since 1986. Field and laboratory analysis results are discussed in this section. Numerical ranges reference the values from the last eight data points, or from the last two years of samples. Wells are located north, south, and west of the Landfill (Figure 2).

#### ***MW-11 (Upgradient/Background Well)***

MW-11 is located near the northeast corner of the site. It is also located near the Ditch, which may have been a source of recharge to the Shallow Aquifer prior to 2009. This well serves as an upgradient monitoring well for the Shallow Aquifer (see Figure 2).

Data collected from MW-11 indicate that slightly acidic conditions of 5.33 to 6.22 pH units prevail with regular exceedances of the field pH lower standard limit. Specific conductance, total dissolved solids, alkalinity, chloride, sulfate, nitrate, ammonia, iron, and manganese are low and relatively stable. The minimum, maximum, and mean for these parameters over the last eight sampling events are available in Table 2-2. Chloride has been found to have an increasing long-term trend at MW-11.

MW-11 remains a representative groundwater quality monitoring well upgradient of the Landfill.

#### ***MW-1, MW-4, MW-6, MW-10, and MW-18 (Side and Downgradient Wells)***

MW-6 is located in the southeast corner of the Landfill and is hydraulically side gradient to the Landfill. MW-1 is located near the southern boundary of the Landfill. MW-10 is located southwest of the Landfill, while MW-18 and MW-4 are located west of the Landfill (see Figure 2). Piezometric head data indicate these last four wells are hydraulically downgradient of the Landfill. Groundwater in these five wells tends to be slightly acidic to neutral with pH mean values range between 5.46 and 6.37 pH units. Chloride concentrations had been decreasing over time after the Slurry Wall installation. However, increasing long-term trends at MW-1 and at MW-6 along with recent increasing trend at MW-4 for chloride have been detected. These detections are consistent

with an increasing trend at MW-11 (upgradient monitoring well). Chloride concentrations for MW-6 are higher than for MW-1 and MW-4 but similar to those found at MW-11.

Sample results from wells MW-1, MW-10 and MW-18 generally exhibit either statistically significant long-term decreasing trends, or no trend for all parameters with the exception of chloride at MW-1. Sample results from wells MW-4 and MW-6 generally have fewer statistically significant long-term decreasing trends (versus no trend found), with only increasing long-term trends found for magnesium, chloride, and sodium from MW-4, and chloride and nitrate from MW-6. This year, sample results from MW-4 didn't have an increasing short-term trend for the parameters including calcium, magnesium, sodium, and pH (Appendix C). Samples from the Shallow Aquifer down and side gradient wells have similar nitrate concentrations to the upgradient well, MW-11.

Field pH was reported below the lower limit for the WQSGWSW secondary criteria in all wells for at least one field sampling event the past year. Arsenic detections are exceeded the WQSGWSW primary criteria in all samples analyzed after adoption of the LLOQ methodology except MW-4 where only two out of four sample results had exceeded similarly to the previous year. Iron exceedances for secondary standards were reported for all sample results from MW-10 and one out of four sample results from MW-1. Manganese exceeded WQSGWSW secondary criteria in all samples collected from MW-1, MW-3, and MW-10. Iron, manganese, and arsenic all occur naturally in groundwater of this region and therefore are believed to be representative of groundwater quality unaffected by Hobart Closed Landfill. Moreover, natural background of arsenic concentration in groundwater for Puget Sound Basin, Washington State is 0.008 mg/L; all of the monitoring arsenic results are below the natural background concentrations (*Natural Background Groundwater Arsenic Concentrations in Washington State*, (Ecology 2016)). No other water quality criteria were exceeded during this period.

VOCs were rarely reported in shallow wells. No volatile organics were detected in these wells during last four quarters.

In general, groundwater sample results from MW-1, MW-6 and MW-10 have relatively higher levels of specific conductance, total dissolved solids, alkalinity, calcium, potassium, and manganese when compared to upgradient groundwater. MW-4 and MW-18 parameter concentrations have declined and stabilized at levels similar to those upgradient for most parameters. The minimum, maximum, and mean for these parameters over the last eight sampling events are listed in Table 2-2. Short-term, there are few statistically significant decreasing trends for these wells. In general, the limited number of statistically significant long-term increasing trends versus decreasing or no trend found indicates water quality is stable or improving in the Shallow Aquifer.

#### **2.3.4 DEEP AQUIFER MONITORING WELL RESULTS**

Quarterly groundwater monitoring has been performed by KCSWD in three deep aquifer wells since 1986. Field and laboratory analysis results are discussed in this section. Numerical ranges reference the values from the last 8 data points, or from the last two years of samples. Wells are located north, south, and west of the Landfill (Figure 2).

### ***MW-25 (Upgradient/Background Well)***

MW-25 is located north of the Landfill and based on piezometric head data, is hydraulically upgradient of the Landfill. This well was installed in 2001 to replace MW-9, which was damaged in the 2001 Nisqually earthquake. The conditions found in MW-25 are considered representative of background water quality in the Deep Aquifer.

Groundwater sample results from MW-25 was reported as slightly alkaline. Alkalinity, chloride, sulfate, and iron (non-detects of iron in samples) levels are low and stable. The minimum, maximum, and mean for reported sample results are consistent with historical values. The sample results demonstrated stable short-term trends for these parameters over the last eight sampling events and are available in Appendix C Table C-3. Long-term sample results show a mix of increasing and decreasing trends for conventional and metal parameters which is corresponding with the previous years' history.

As an upgradient well, samples from MW-25 exceeded the WQSGWSW criteria for arsenic in all four recent samples.

Dichlorodifluoromethane was detected in all four samples in MW-25 but did not exceed WQSGWSW or 40 CFR Part 141 – National Primary Drinking Water Regulation (Federal Drinking Water criteria). There were no other VOCs detected in MW-25 during this period.

### ***MW-7 and MW-3 (Downgradient Wells)***

MW-7 is located south of the Landfill, and MW-3 is located west of the Landfill. Based on piezometric head data, these two wells are hydraulically down gradient of the Landfill.

Groundwater samples from MW-7 and MW-3 reported as slightly alkaline, with mean alkalinities of 126.9 and 70.4 mg/L, respectively. Specific conductance, total dissolved solids, alkalinity, sulfate, calcium, magnesium, potassium and sodium levels in MW-7 and MW-3 were higher than those in upgradient well MW-25. In addition, sample results from MW-3 had higher concentrations of manganese. The minimum, maximum, and mean for these parameters over the last eight sampling events are available in Table 2-2.

There were no statistically significant short-term trends (increasing or decreasing) from MW-3 and MW-7, except for increasing chloride and pH for MW-3. However, both monitoring points have a mix of long-term increasing and decreasing trends.

MW-7 demonstrated long-term either decreasing or unchanged trends for metals and conventionals. MW-3 showed long-term increasing trends for specific conductance, alkalinity, chloride, sulfate, total dissolved solids, and five metals (calcium, magnesium, manganese, potassium, and sodium), all of which are major ionic species. All of these parameters met regulatory criteria except for manganese that exceeded secondary standards. Monitoring will continue to assess any future changes to groundwater quality characteristics.

Recent changes to lower reporting limits resulted in quantifiable results for 1,1-dichloroethane in samples collected at MW-7 in the 1<sup>st</sup> quarter of 2022. However, this result was qualified as estimated (“JT” qualified) by the contract lab, KCEL, due to being reported below the LLOQ.

Declining concentrations had been tracked from 1992 through 2008 with a 0.2 µg/L reporting limit. MW-7 sample results for a 1,1-dichloroethane was quantified at 0.104 µg/L, just above the detection limit (non-detect samples are below 0.1 µg/L). This is consistent with the long-term declining trend, which also showed no trend for short-term at MW-7. No other volatile organic compounds were detected in MW-3 or MW-7.

Arsenic was detected in all four MW-3 and MW-7 samples for the past year. Detections are implicitly exceedances of the primary WQSGWSW criteria; however, the results are also below the natural background concentrations for groundwater Puget Sound Basin in the State of Washington which is 0.008 mg/L (*Natural Background Groundwater Arsenic Concentrations in Washington State*, (Ecology 2016)).

### 2.3.5 SLURRY WALL PERFORMANCE

The Slurry Wall containment continues to isolate the Shallow Aquifer beneath the Landfill from the local groundwater flow system. Pumping wells installed beneath the solid waste and inside the Slurry Wall have historically lowered the groundwater table below the base of refuse. The water elevation outside of the Slurry Wall has remained consistently above the water elevation inside (see Figure 5). As a result, an inward hydraulic gradient has been created resulting in a system which reduces the possibility of breakthrough of contaminants and off-site transport.

Concurrent with the construction of the Slurry Wall, the northern half of the Landfill was closed with an HDPE final cover. The southern half was later closed also with an HDPE final cover in 1994. Consequently, local recharge to the aquifer was reduced.

Six indicators have been used to evaluate the Slurry Wall performance: chloride, arsenic, manganese, 1,1-Dichloroethane, 1,1,1-Trichloroethane, and *cis*-1,2-Dichloroethene. Chloride is an early indicator of leachate, and manganese is sensitive to redox conditions. Their movement through groundwater is controlled by different chemical processes. Chloride migration is not retarded by such processes as adsorption, cation exchange, biological uptake or redox processes. The distribution of manganese, however, is strongly controlled by redox processes. Reducing conditions permit manganese to dissolve and be transported in groundwater. A reducing condition prevails when oxygen is depleted by waste degradation and sustained by the presence of BOD and anaerobic metabolism. Thus, manganese may be an indicator of landfill impacts.

Increasing long-term trends at MW-1 and at MW-6 along with recent increasing trend at MW-4 for chloride have been detected, but these detections are consistent with an increasing trend at MW-11 (upgradient monitoring well). Moreover, chloride in all of the down and side gradient wells has been reduced to levels found in MW-11 (background). Manganese levels have been reduced in all wells but remain elevated relative to MW-11 in MW-1, MW-10 and MW-18.

Until the analytical laboratory change, arsenic had only been detected consistently in one Shallow Aquifer well, MW-10, and one Deep Aquifer well, MW-25. Recent detections in all wells are due to the switch to LLOQ reporting methodology. For both MW-10 and MW-25, arsenic concentrations have been consistently decreasing over time. Groundwater samples from all of the

wells showed either long-term decreasing trends or relatively stable concentrations for arsenic detections.

Organic compounds have been detected with relatively low frequency and at low level both prior to and since construction of the Slurry Wall. The concentration levels for *cis*-1,2-dichloroethene, 1,1-dichloroethane, and 1,1,1-trichloroethane have been used to evaluate the success of remediation indicated by their decrease over time. There have been no significant changes in sample detections of these compounds including these last four quarters in any shallow wells since 2008.

A summary of the performance of the Slurry Wall and drawdown wells showing water quality prior to containment and after containment is presented in Table 2-3.

This water quality evaluation, in conjunction with water level data shown in the potentiometric mapping and the trend analyses, demonstrates that the Slurry Wall is functioning as designed: maintaining groundwater elevation separation below the waste by preventing groundwater migration inside the wall perimeter. Elevated groundwater levels below waste are attributed to increased cover infiltration due to higher precipitation levels since 2009.

## CHAPTER 3: LANDFILL GAS

---

Landfill gas is monitored by a network of compliance probes installed around the perimeter of the Landfill and ambient air stations around the property boundary. Landfill gas compliance probes are monitored monthly. Landfill gas ambient stations are monitored quarterly. The landfill gas probes and ambient stations monitoring results can be found in Appendix G. There were no methane detections in the period of October 2021 through September 2022. Gas probe monitoring data are provided in Appendix G and their locations are shown in Figure 3.

In 2019, the landfill gas probe GP-7 was decommissioned by over-drilling using hollow-stem auger methods. A new gas probe, GP-9, was installed as a replacement for GP-7. Additional details for decommissioning and installation of GP-7 and GP-9 can be found in *Landfill Gas Probe Installation and Decommissioning Technical Memorandum*, (Aspect Consulting, 2019).

## **CHAPTER 4: SUMMARY AND CONCLUSIONS**

---

The conclusions of this groundwater quality evaluation report are presented according to aquifer and time period.

### **4.1 SHALLOW AQUIFER**

The Shallow Perched Aquifer is an unconfined water table aquifer that has historically saturated lower portions of the solid waste beneath certain areas of the Landfill. Since completion of the Slurry Wall remediation construction in 1989, the shallow water table has been contained from coming into contact with refuse, and the groundwater gradient around the Landfill has been altered to minimize off-site transport from beneath the Landfill.

Information presented in this report suggests that on-site monitoring wells installed in the Shallow Aquifer and located hydraulically downgradient of the Landfill may have historically been influenced by landfilling activities. When monitoring began in 1986, the downgradient wells had elevated levels of some leachate indicator constituents with respect to the upgradient wells. Since 1986, these constituents have become progressively less concentrated in downgradient wells, as a result of improved landfill site conditions and Shallow Aquifer containment activities, particularly installation of the low permeability bentonite Slurry Wall.

Wells in the Shallow Aquifer displaying historic impacts from landfilling activities consisted of MW-1, MW-4, MW-6, and to a lesser extent, MW-10 and MW-18. These wells are located along the west and south perimeter of the landfill. Concentrations were highest prior to completion of the Slurry Wall. Trend analyses show that statistically significant decreases in long-term trends of indicator parameters have occurred in the side and down gradient wells. Recent short-term trend analysis indicates relatively stable results with no increasing trends for pH in MW-4, and chloride in MW-6 and MW-11 (upgradient).

VOCs associated with Shallow Aquifer detections prior to and in the early Slurry Wall phase have decreased with only three estimated volatile detections reported since December of 2008, excluding suspected analytical laboratory contaminant volatile results. Recent detections are attributed to lower detection limits (below previous reporting limits), which further confirms that concentrations have declined and are detectable only infrequently.

Current water quality conditions in the Shallow Aquifer continue to approach background constituent concentrations and no future increases in contaminant levels are expected given current site wide trends.

In general, water quality in the shallow aquifer has improved and demonstrates stability in current conditions.

### **4.2 DEEP AQUIFER**

The refuse is located in excess of 100 feet above the Deep Aquifer and is separated from the deeper water bearing zone by about 80 feet of dry or moist soils. A low permeability ( $10^{-6}$  cm/sec)

perching layer of the OUD is continuous beneath the Landfill and separates the two hydrogeologic systems. The lack of moisture in the soils indicates that hydraulic connection between the fill and the groundwater is not strong and the soil capacity to retard contaminants is enhanced because of unsaturated conditions.

General geochemistry parameters at MW-7 are elevated relative to the upgradient well, but all have shown relatively stable concentrations over both the long-term and short-term periods. In addition, the concentrations of these parameters are below both Federal Drinking Water and WQSGWSW exceedance criteria. The frequency of VOC detections in the Deep Aquifer has decreased considerably over time, with only dichlorodifluoromethane detected regularly in MW-25, an upgradient well, and 1,1-dichloroethane having recent detection in MW-7. Both of these detections are below the WQSGWSW criteria.

Long-term, ionic species analytes (e.g., conductivity, sodium, chloride, etc.) have shown increasing trends at both upgradient well MW-25, and downgradient MW-3, over time. This may indicate that an off-site, upgradient source is impacting the Deep Aquifer water quality beneath the Landfill.

In general, the groundwater quality in the deep aquifer has improved over time.

#### **4.3 RECOMMENDATIONS**

Recommendations for the next year for Hobart Closed Landfill are:

- Maintain engineered controls, including the engineered cover, the leachate extraction system, landfill gas treatment system, and the stormwater management structures.
- Continue monitoring water level, field parameters and groundwater sampling on a quarterly basis at all wells in the current monitoring network, and landfill gas compliance probe monitoring on a monthly basis.
- Continue evaluating the engineering control systems: landfill cover, containment wall, leachate extraction system, landfill gas collection and treatment system, and stormwater management structures to determine whether modifications are needed to meet regulatory and operational criteria.
- Perform appropriate pumping needed to maintain hydraulic gradients and waste isolation. In 2021, Public Health – Seattle and King County (Public Health) granted a variance for a period of three years from the requirements for groundwater extraction from the Slurry Wall.
- Evaluate the groundwater monitoring program in 2023 to determine whether modifications to frequency and parameters are indicated.

RE: Potentiometric Groundwater Surface Maps & Groundwater Velocity Calculations  
Water Year 2021-2022 Results  
Hobart Closed Landfill, King County, Washington  
Project No. 1033596 – Task 23.14.137.44

---

The King County Water and Land Resources Division (WLRD) submits this memorandum report on groundwater conditions during the 2021-2022 water year for the shallow and deep aquifers beneath the Hobart Closed Landfill (Landfill). King County Solid Waste Division (SWD) personnel measured depth to water levels at the Landfill quarterly during the 2021-2022 reporting year. These measurements were received by WLRD on August 28, 2022 and were used to:

1. Evaluate the potentiometric groundwater surface for the shallow and deep aquifers;
2. Determine the groundwater flow direction and horizontal gradients for the shallow and deep aquifers;
3. Calculate the groundwater flow velocities for the shallow and deep aquifers; and
4. Calculate the horizontal gradient across the slurry wall for four sets of paired wells.

There have been no significant changes in the interpreted groundwater conditions since the previous annual report (fourth quarter 2020 – third quarter 2021) was submitted.

## **Groundwater Elevation Data**

The SWD measured groundwater levels at 14 groundwater monitoring wells during the fourth quarter of 2021, and the first, second, and third quarters of 2022 (groundwater reporting year). Groundwater monitoring wells are completed in the shallow and deep aquifers located outside of the slurry wall. Ten additional wells located inside the slurry wall were also visited for groundwater level measurements, one of which, LP-7, was noted as dry.

Table B-1 lists the groundwater monitoring well identifications, locations, top of well casing, measured depth to groundwater levels, and calculated groundwater elevations for monitoring wells screened in the shallow and deep aquifers, as well as for the water-bearing zone located inside the slurry wall.

### **Shallow Aquifer and Inside Slurry Wall**

Groundwater in the shallow aquifer is monitored by wells MW-1, MW-4, MW-6, MW-10, MW-11, MW-16, MW-18, MW-21, MW-22, MW-26 and MW-27. Figures B-1, B-2, B-3, and B-4 show calculated groundwater elevations at well locations screened in the shallow aquifer during the 2021-2022 reporting year.

During the 2021-2022 reporting year, average water level measurements inside the slurry wall were 9.85 ft (fourth quarter 2021), 6.59 ft (first quarter 2022), 4.63 ft (second quarter 2022), and 3.26 ft (third quarter 2022) below average groundwater levels outside the wall. The magnitude of hydraulic separation between the water levels inside of the slurry wall, and water levels outside of the slurry wall are similar to those calculated in previous reporting years.

### **Deep Aquifer**

Groundwater in the deep aquifer is monitored by wells MW-3, MW-7, and MW-25. Figures B-5, B-6, B-7 and B-8 show calculated groundwater elevations at well locations screened in the deep aquifer during the 2021-2022 reporting year.

## **Direction of Groundwater Flow**

Interpreted groundwater flow directions in the deep and shallow aquifer are shown, where possible, in Figures B-1 through B-8. Table B-2 lists the flow direction for the shallow and deep aquifers based on recorded water level measurements and contoured groundwater elevations for the 2021-2022 reporting year.

### **Shallow Aquifer**

Figures B-1, B-2, B-3, and B-4 show interpreted groundwater flow directions, where possible, for the shallow aquifer during the 2021-2022 reporting year. Shallow aquifer flow direction interpretation only uses data from outside the slurry wall. Calculated groundwater elevations and interpreted groundwater potentiometric surface contours indicate that groundwater in the shallow aquifer generally flows towards the west around the slurry wall in the shallow aquifer. Limited interpretation is shown on Figures B-3 and B-4 for the shallow aquifer during the period with lower water levels.

### **Deep Aquifer**

Figures B-5, B-6, B-7, and B-8 show interpreted groundwater flow directions for the deep aquifer during the 2021-2022 reporting year. Calculated groundwater elevations and interpreted groundwater potentiometric surface contours indicate that groundwater in the deep aquifer generally flows west-southwest.

## **Groundwater Parameters**

Table B-2 presents a summary of the groundwater parameters for the shallow and deep aquifers. The hydraulic conductivity and effective porosity values are based on the data referred to in *Phase 1 – Groundwater Flow Model Construction and Calibration Report: Hobart Closed Landfill* (Aspect, 2020).

The geometric mean of horizontal hydraulic conductivity was reported to be 1427 feet per day (ft/d) in the shallow aquifer, and 2.35 ft/d in the deep aquifer (Aspect, 2020). The porosity was reported as 30 percent in both aquifers based on values estimated from values reported for similar hydrogeologic units (Aspect, 2020).

Average horizontal hydraulic gradients for the shallow aquifer were:

- 0.0024 ft/ft (fourth quarter 2021),
- 0.0027 ft/ft (first quarter 2022),
- 0.0017 ft/ft (second quarter 2022), and
- 0.0015 ft/ft (third quarter 2022).

The average horizontal hydraulic gradients for the deep aquifer were:

- 0.0288 ft/ft (fourth quarter 2021),
- 0.0283 ft/ft (first quarter 2022),
- 0.0286 ft/ft (second quarter 2022), and
- 0.0291 ft/ft (third quarter 2022).

Gradients across the slurry wall in the shallow aquifer for four sets of paired wells are included in this report (Table B-3) and the locations of these paired wells are shown in Figures B-1, B-2, B-3, and B-4 with symbols similar to geologic cross-section lines. For example, the northern paired well set (MW-27 and LP-3) is symbolized as N-N' and also

identified in Table B-3 with this notation for consistency. For each paired well, the nomenclature is the same, where the first letter of the symbol is located at the well outside the slurry wall in the shallow aquifer, and for the second, at the well inside the slurry wall.

The largest calculated gradients for all the paired wells occurred during the fourth quarter of 2021. The gradients across the upgradient side of the slurry wall are the highest gradients for all quarters and paired wells, with a maximum gradient of 0.077 ft/ft (paired wells MW-16 and LP-8 (E-E')). The gradients across the downgradient side of the slurry wall are the lowest gradients for all quarters and all paired wells, with a minimum gradient of 0.008 ft/ft during the third quarter of 2022 (paired wells MW-4 and LP-1(W-W')). Overall, average gradients range from 0.021 to 0.057 ft/ft for all paired wells during the 2021-2022 reporting year.

Average horizontal groundwater velocities calculated for the shallow and deep aquifers are based on spatial differences in aquifer parameters, hydraulic gradients, and calculations using the following formula:

$$\text{where: } v = \frac{I}{n_{eff}} K \frac{\Delta H}{\Delta L}$$

$v$  = Groundwater velocity [L/t]

$n_{eff}$  = Effective porosity [dimensionless]

$K$  = Hydraulic conductivity [L/t]

$\frac{\Delta H}{\Delta L}$  = Hydraulic gradient [L/L]

The horizontal groundwater velocities calculated for the shallow aquifer ranged from 7.2 ft/day to 12.8 ft/day, westward around the slurry wall. Horizontal groundwater velocities calculated for the deep aquifer ranged from 0.22 ft/day to 0.23 ft/day in a west-southwest direction. The magnitude and direction of groundwater flow for the shallow and deep aquifers are consistent with the range of groundwater velocities and flow directions reported during 2020-2021, the last annual reporting year.

**Notes:**

1. Easting and northing coordinates are based on Washington State Plane Coordinate System. North Zone (NAD 83/11).
  2. Elevations reported in feet (ft) above mean sea level (MSL) based on the North American Vertical Datum of 1988 (NAVD 88).
  3. Water level measurements made by SWD personnel.
- DRY Well indicated as dry  
NA Not applicable  
\* LP-7 confirmed dry using video camera inspection (May 6, 2021).

**Table B-2: Groundwater Parameters – Reporting Year 2021-2022**  
Hobart Closed Landfill  
King County, Washington

| Groundwater Zone Adjacent to or Beneath Landfill | Monitoring Event | Horizontal Hydraulic Conductivity <sup>1</sup> (K) | Horizontal Hydraulic Gradient <sup>2</sup> (DH/DL) | Effective Porosity <sup>1</sup> (n <sub>eff</sub> ) | Horizontal Groundwater Velocity (v) | General Groundwater Flow Direction |

**Notes**

1. Shallow aquifer parameters (horizontal hydraulic conductivity geometric means and porosity values) are from **Phase 1 – Groundwater Flow Model Construction and Calibration Report: Hobart Closed Landfill** (Aspect, 2020).
2. Horizontal hydraulic gradients based on average of gradients measured at several points, where possible, from maps shown Figures B-1 through B-4.

**Table B-3: Gradients across the Slurry Wall – Reporting Year 2021-2022**

Hobart Closed Landfill  
King County, Washington

D = Decreasing concentrations  
I = Increasing concentrations  
-- = There is no trend.  
Probability = probability that the null hypothesis (Ho) is true.  
Significant = The trend is significant at a p = 0.05 level.
