APPENDIX B
APRIL 10, 2012 TECHNICAL MEMORANDUM
RESULTS OF VAN STONE MINE BACKGROUND
SAMPLING AND NATURAL BACKGROUND
METAL CONCENTRATIONS

TECHNICAL MEMORANDUM

DATE: April 10, 2012

TO: Brendan Dowling, Project Manager, Ecology Eastern Division

FROM: Steven Hughes

RE: Results of Van Stone Mine Background Sampling and Natural Background Metal

Concentrations

17800-11

CC: Project File

This technical memorandum presents the draft natural background metal concentrations in soil and sediment at the Van Stone Mine. The natural background concentrations were developed based on statistical analysis of data generated from laboratory analysis of samples collected from areas near the mine. Background surface water samples were collected, but because of the high number of non-detects in the analytical results, background metal concentrations were not calculated.

INTRODUCTION

The Van Stone Mine (Site) is located in the headwaters of the Onion Creek Watershed (Figure 1), 23 miles northeast of Colville, Washington. Historical mining activities at the mine have resulted in environmental impacts on the Site and nearby areas. In 2011, Ecology asked Hart Crowser to prepare a work plan for conducting a Remedial Investigation/Feasibility Study (RI/FS) of the Site. The work plan was developed to comply with cleanup requirements administered by Ecology under the Model Toxics Control Act (MTCA) [WAC 173-4300-360 through 173-340-390]. The final RI/FS work plan (dated September 11, 2011) was approved by Ecology and the investigation subsequently authorized.

Field work at the Site started with collection of background samples. The following sections discuss the basis for using natural background metals concentrations, sample collection, and data analysis used to develop draft natural background for the Site (Table 1). The information presented in this memorandum will be used in the RI/FS and included in the final RI report.

BASIS FOR NATURAL BACKGROUND

Based on our review of historical site information, the Onion Creek watershed is a mostly rural setting with limited residential development along the creek and its tributaries. The Onion Creek Elementary School is located about 1/3 mile west of the western extent of mine features (Lower Tailings Pile). In addition to the Van Stone Mine, logging appears to be the only large commercial/industrial activity present in the watershed.

As part of work plan preparation, we visited the Site in May 2011 to observe current conditions in the watershed. Observed conditions in the watershed were found to be consistent with historical information reviewed before the site visit. Based on the historical information and observed watershed conditions, we concluded that it was most likely that concentrations of hazardous substances on and in the vicinity of the Site are related to releases from the Site, rather than the result of human activities. Thus, the conditions in the watershed are consistent with using a natural background rather than an area background as defined in MTCA [173-340-200]. Where Method A or B cleanup levels are below background concentrations cleanup levels may be established at background concentrations.

Two concerns evaluated in establishing background were: 1) the presence of outcrops of the dolomite host rock that were not mined or changed by mining activity, which may contain naturally elevated metal concentrations; and 2) the lower tailings pile, which is located in a sub-watershed in Onion Creek in which the dominant soil rock types are glacial drift and igneous rock (Figure 1). These conditions presented a potential need for multiple natural backgrounds at the Site. To evaluate this need, the background samples were divided and pooled and a statistical comparison was made on the two data sets, which is discussed in a later section of this memorandum.

Sampling Locations and Sample Size

During development of the RI/FS work plan, analytical datasets were not identified that were suitable for establishing background, as defined in MTCA [WAC 173-340-200, and 709]. To address this data gap, the work plan identified 15 potential background sample locations in the Onion Creek watershed. Selection of sample locations was based on watershed geology, topography, habitat, aerial photography, rural development, and historical mining operations, including the potential extent of areas impacted by mining. The number of samples collected for each media (soil, sediment, surface water) was based on a minimum of 10 samples required under MTCA for establishing a natural background. The minimum number of samples was increased to 15 to provide sufficient sample coverage in the event that any sample results were unusable.

17800-11

Page 3

Soil, Sediment, and Surface Water

The background sampling locations presented in the work plan were approximate and adjusted based on field conditions encountered at the time of sampling (i.e., lack of flow in creek or tributary, or access to a sample location). During the field work, as presented in the work plan, 15 samples of each media were collected; however, one location (BG-12) was inadvertently located on the southeast tributary to Onion Creek, rather than a smaller creek tributary. Location BG-12 is potentially mining impacted and was excluded from the final background sample set. All data analysis and draft background concentrations presented in this memorandum are based on a sample size of 14.

Groundwater

Groundwater at the Site may be environmentally impacted; however, development of background for metals in groundwater was only partially addressed. This approach was based on discussions during work plan development with Ecology. Natural background metals concentrations for groundwater are difficult to establish because data on historical groundwater quality and groundwater flow in the glacial material and igneous rock fractures/faults is lacking. Collecting samples is complicated by the size and topography of the area that needs to be sampled.

As a starting point for discussions with Ecology on evaluating potential mining impacts on groundwater, six candidate domestic wells were identified and groundwater samples were collected and submitted for laboratory analysis. As with other sampling locations, the wells actually sampled were adjusted based on discussions with well owners or their lack of availability at the time of the field work.

SAMPLE COLLECTION AND TESTING

Background samples were collected during field investigation activity at the Site in October 2011. Weather conditions were less than ideal during sampling with persistent periods of precipitation, resulting in increased stream flows during field work. Conditions observed at sampling locations are summarized in Table 2.

The background samples were submitted to Test America in Tacoma, Washington, an Ecology-accredited laboratory, for chemical analysis. A quality control/quality assurance (QA/QC) review of background data received from the laboratory was performed. The data was found to be usable as reported from the laboratory. The full data set has been uploaded to Ecology's Environmental Information Management (EIM) website.

Washington State Department of Ecology April 10, 2012 17800-11 Page 4

The following sections summarize the background sampling protocols from the Sampling and Analysis Plan (SAP), protocol deviations, and sample location descriptions.

Soil Sample Collection Protocols

Protocols for soil, sediment, and groundwater are presented in the SAP. The following three soil protocols are outlined for clarity.

- Each background soil sample collected was a five-point composite sample. At each sampling location a center sampling point was first located and marked with a pin flag. Then a measuring tape was used to delineate an approximately 20-foot by 20-foot square area with pin flags marking the corners of the square. At the majority of locations, the creek channel was narrow allowing sub-samples to be collected from both sides of the creek. This placed the corner sampling points at 10 or more feet from the creek channel. At some sample locations, rock outcroppings or thick undergrowth was present. When this occurred the sampling grid was established completely on the opposite side of the creek channel.
- To avoid natural variations in the shallow soil column, background samples were collected from a depth of 3 to 6 inches. For consistency, the surface layer (i.e., grass, leaves, or forest duff) was removed before collecting each soil sample.
- In cases where a sample location was near dirt roads, telephone and power line right-of-ways, and home sites, care was taken to locate the sample in an area not affected by land disturbance.

Sampling and Analysis Plan (SAP) Deviations

- During the field work, as presented in the work plan, 15 samples of each media were collected; however, one location (BG-12) was inadvertently located on the southeast tributary to Onion Creek rather than in an upgradient small tributary to the creek. The location sampled is potentially mining impacted and was not included in the final background sample set.
- All sediment samples were collected with a pre-cleaned stainless steel spoon in shallow and low energy pools. Care was taken to slowly sample through the water column in order to capture the <2mm fraction of sediment at each location. This procedure was used instead of the McNeil sampler because of the presence of large gravel and cobbles in the creek bed, and the narrow creek channels at many locations.</p>

Background Sample Location Descriptions

Soil, sediment, and water samples were collected from background locations in the upper portion of the Onion Creek watershed (Figure 1). The 14 sampling locations are summarized as follows:

- BG-1,2,3,4: Collected east of the Lower Tailings Pile on the northeast tributary;
- BG-7: Collected south of the Open Pits and topographically uphill from the open pits;
- BG-6,8,11: Collected east of the open pits and waste rock along a tributary which drains into the southeast tributary;
- BG-10: Collected southwest of the Upper Tailings Pile along a tributary which drains into the southeast tributary;
- BG-9,13,14: Collected on Onion Creek above the confluence with the southeast tributary; and
- BG-5: Collected east of the Onion Creek watershed divide.

BG-12 was collected on the southeast tributary upstream of the confluence with Onion Creek. As mentioned earlier, this sample was not included in the background data set. A brief description of the background locations and observations are summarized in Table 2.

DEVELOPMENT OF NATURAL BACKGROUND FOR SOIL AND SEDIMENT

At the Site, rock outcrops containing economic or sub-economic grade ore deposits located outside of the area mined and not altered by mining activity can be considered part of the natural metal background. The host rock for the lead-zinc deposit at the Van Stone Mine is the dolomite unit of the Metaline limestone. As shown on Figure 1, outcrops of the Metaline Formation are limited to higher topographic areas in the southern portion of the watershed. In his master's thesis, which describes the geology of the Van Stone Mine, Neitzel (1972) concluded that the lead-zinc ore was present in the dolomite unit of the Metaline Formation prior to emplacement of the Spirit pluton. This conclusion implies that high metal concentrations associated with ore deposition would likely be limited to rocks of the Metaline Formation. The higher metal concentrations could potentially create a justification for using multiple backgrounds in different areas of the watershed.

To address this concern, the first part of determining natural background was to assess whether background concentrations should be evaluated separately by the dominant geologic formations which weather and form the soils and sediments in the watershed (Figure 1). This was done by dividing the background sample set into two populations of seven samples each. The two populations were based on whether the background samples were collected from or downgradient of the Metaline limestone and older formations (dolomitic) or background samples were collected from continental drift or downgradient of the igneous rocks of the Spirit pluton (non-dolomitic).

Washington State Department of Ecology April 10, 2012 17800-11 Page 6

While the small sample sizes make the comparisons less robust then desired, they are still considered informative in evaluation of potential multiple backgrounds in soil and sediment.

The software and statistical methods recommended in EPA's ProUCL statistical software package were used both for hypothesis testing to determine if there were statistically significant differences between the two geological units and to calculate the background concentrations¹.

Comparisons between Geologic Units

Nonparametric hypothesis testing methods were used for making the background comparisons. Nonparametric methods were selected because they:

- Can be used on data sets with normal and non-normal distributions;
- Have a good performance for a wide variety of data distributions; and
- Can handle data sets with non-detected values.

Following EPA's ProUCL recommendations, the nonparametric Wilcoxon-Mann-Whitney (WMW) test was used when the dolomitic or non-dolomitic data sets contained non-detect (ND) values.² However, the WMW test was not used on data sets with multiple detection limits. The Gehan test was used when multiple detection limits were present in either of the data sets. The Gehan test was used only for comparing sediment mercury and thallium concentrations and soil thallium concentrations since these were the only cases with multiple detection limits for non-detected results.

With the exception of zinc sediment background samples, there were no statistically significant differences between samples collected from dolomitic and non-dolomitic areas in the watershed (Table 3). The apparent zinc difference was influenced by a single sample (BG-10) which had an anomalously high sediment concentration (3,800 mg/kg) and was located along the northeast-southwest trend of the Van Stone ore deposit.

ProUCL background comparison results are summarized in Table 1 and output files are provided in Attachment A.

¹ ProUCL version 4.00.005 software and supporting documentation are available online at http://www.epa.gov/esd/tsc/software.htm.

² Although ProUCL recommends the Quantile test be run in parallel with the Wilcoxon-Mann-Whitney test, the Quantile test is only used to detect a shift to the right in the right tails of the site and background data sets. Since the Quantile test has several statistical limitations that may apply to Van Stone Site data sets, it was not used in the background comparisons.

17800-11

Page 7

Natural Background Calculation

Because the data do not support calculating separate background concentrations for the different geological formations, background concentrations were calculated using the pooled data set of 14 background samples collected across the geologic units present in the watershed. The ProUCL test used was the "Background" using the "With NDs" setting and a confidence level of 0.90. For calculating background, MTCA [WAC 173-340-709(3) states that:

"For lognormally distributed data sets, background shall be defined as the true upper 90th percentile or four times the true 50th percentile, whichever is lower" and "For normally distributed data sets, background shall be defined as the true upper 80th percentile or four times the true 50th percentile, whichever is lower."

MTCA also allows "Other statistical methods to be used if approved by the department" [of Ecology].³

In cases where data fit more than a single distribution, the following hierarchical order was used to calculate the background concentration: lognormal, normal, gamma, and non-parametric.

A summary of calculated surface soil and sediment background metal concentrations for the pooled datasets are shown in Table 1. It is important to note that the calculated natural background concentrations are representative of the immediate, non-impacted surroundings of the Van Stone Mine and may not be representative of natural background concentrations of the larger surrounding region. ProUCL raw statistics and background concentration output files are provided in Appendix A.

Table 2 - Descriptions of Background Sample Locations

	Collection	Channel Description (feet and cubic feet per			
Sample ID	Date	second)	General Location	Sampling Area Observations	Observations of Current or Historical Activity
BG-1	10/6/2011	~3' wide, ~20 cfs.	Along NE tributary, above lower tailings pile.	Below confluence with small tributary, above road. Grassy, organic, lots of worms in soil sample.	Mowed area. Apparently previously used as pasture.
BG-2	10/4/2011	~2-3' wide, ~10 cfs.	NE tributary, upstream from Lower Tailings Pile.	Creek bottom has been logged previously. Heavy tree cover and undergrowth, in an ~50' wide creek basin. Some marshy areas with skunk cabbage.	Previously logged. Burned wood observed in soil sample.
BG-3	10/6/2011	~1.5' wide, ~ 2-5 cfs.	Upstream of Lower Tailings Pile, NE tributary.	Small stream between logged areas. Stumps, downed trees, newer tree growth. Creek disappears under tree roots and forest duff.	Previously logged. Appears to be within streamside management zone.
BG-4	10/6/2011	~1' wide, ~ 2-3cfs.	NE tributary, upstream from lower tailings pile.	Small stream between logged areas. Small trees, heavy undergrowth, downed logs. Creek disappears under logs, debris and forest duff. Two grouse in area.	Clearcuts nearby. Upstream from logging road.
BG-5	10/5/2011	~3' wide, ~20 cfs.	Above main mine area, on tributary that flows into different watershed.	Small creek flowing within wider flat valley (50' wide). Heavily forested with downed logs, minor undergrowth. Creek disappears below forest litter in some areas.	Between clearcuts, upstream from logging road. Old flagging tape observed near one soil subsample.
BG-6	10/4/2011	~1.5' wide, ~ 2-5 cfs.	Above main mine area, on tributary that flows into SE tributary.	Small creek flowing within wider flat valley (~ 20-30' wide). High tree cover, downed trees, little undergrowth. Aerial photos show heavily logged away from stream area.	Between clearcuts, uphill from logging road.
BG-7	10/4/2011	~1.5' wide, ~20-30 cfs.	Above main mine area, on tributary that flows into SE tributary.	Small creek with steep drainage banks above logging road. Heavy tree cover and undergrowth; Downed logs and mossy banks.	Near logging road.
BG-8	10/3/2011	~1.5' wide, 2-6" deep, ~5 cfs.	Above main mine area, on tributary that flows into SE tributary.	Small creek flowing within wider flat valley (~ 50' wide). Downed trees crossing creek, low shrubs and plants in valley, forested on upper banks. Aerial photos show heavily logged away from stream area.	~2 to 5 pieces of clear plastic from old milk carton found in creekbed
BG-9	10/7/2011	~10' wide, ~ 200 cfs.	Onion Creek, above confluence with SE tributary.	Heavily forested, appears unlogged. Downed trees, undergrowth.	Near forest road, ATV trails
BG-10	10/5/2011	~3' wide, ~1-2 cfs.	Small tributary upstream from upper tailings pile, feeds into SE tributary.	Small creek, appears to be intermittent. Small trees, tree stumps, downed trees, minor undergrowth.	~50 feet from road. Previously logged
BG-11	10/8/2011	~2' wide.	Above main mine area, on tributary which flows into SE tributary.	Small creek in open area, many small trees, medium undergrowth. Game animal trail.	Upstream from old road bed. Clearcuts to both sides of creek area.
BG-12	10/7/2011	~8-10 wide, ~150 to 200 cfs.	SE tributary, downstream from mine, above confluence with Onion Creek. Not true background sample.	Grassy area with small trees and shrubs. Near road.	~150' from Onion Creek Road.
BG-13	10/5/2011	6-8' wide, ~200 cfs.	Onion Creek, above confluence with SE tributary.	Flat creekbed, area cleared for DNR management, large trees, some downed logs. Fish in creek.	Area cleared of undergrowth for DNR management.
BG-14	10/6/2011	~8' wide, ~100 cfs	Onion Creek, above confluence with SE tributary.	Flat creekbed, undercut banks, medium dense forest undergrowh, trees and stumps.	~50 feet from road.
BG-15	10/7/2011	~3' wide, ~50 cfs	Tributary that drains into SE tributary.	Heavy undergrowth, logs, trees and stumps.	Upstream from very old logging road. Two old log (early 1900s?) cabin structures downstream on old road.
