Technical Memorandum

| То: | Mr. Dale Myers, Washington State Department of Ecology |
|----------|--|
| From: | Cayla Whiteside, Ryan Hultgren |
| Site: | Circle K 1461, 2350 24 th Avenue East, Seattle, Washington |
| Subject: | Engineering Design Report Addendum, Contract C2100069 KJ 2196008.00 |

This Technical Memorandum presents Kennedy/Jenks Consultants, Inc.'s (Kennedy Jenks) addendum to the Engineering Design Report (EDR) referenced in the State of Washington, Department of Ecology (Ecology) Contract C2100069, Appendix C, Statement of Services, Task 2B Engineering Design Report, Item c. A final EDR report was submitted to Ecology on 10 December 2021 following comments provided by Ecology as part of this contract. The following addendum includes updated cost estimations for further comparison of cleanup alternatives.

The Circle K 1461 Site (site) is a former gasoline service station that operated from 1968 to 1990. The site is located at 2350 24th Avenue East in Seattle, Washington (Figure 1), on the southeastern corner of the intersection of 24th Avenue East and East McGraw Street. Four gasoline underground storage tanks (USTs), one pump island, one waste oil UST, and one heating oil UST were formerly located at the site (Figure 2). The site was redeveloped in 1990 and 1991, and two businesses currently operate at the site. The USTs were removed during redevelopment, and additional remedial and investigation actions were conducted at the site between 1989 and 2017. Residual petroleum hydrocarbons are present at the site in soil and groundwater. The primary contaminants of concern (COCs) in soil and groundwater are gasoline range organics (GRO) and benzene, toluene, ethylbenzene, and xylenes (BTEX).

The remedial alternative selected in the 2017 Remedial Investigation/Feasibility Study (RI/FS) and Cleanup Action Plan (CAP) was a combination of *in situ* bioremediation through a groundwater recirculation system with injection of bioaugmentation reagents for the treatment of groundwater and saturated soils, and a soil vapor extraction (SVE) system to address hydrocarbons in vadose zone soils, as well as the mitigation of potential vapor intrusion (VI). As part of the data gaps process and alternatives analysis completed during pre-design, an alternative process option of multiple phase extraction (MPE) coupled with *in situ* bioremediation was identified and chosen. Similar to SVE, MPE addresses residual hydrocarbon contamination of the vadose zone and can also be designed to protect against VI.

Mr. Dale Myers, Washington State Department of Ecology November 21, 2023 Circle K 1461 Page 2

Comparison of Cleanup Alternatives

Both the remedial option detailed in the RI/FS and CAP (SVE and groundwater recirculation) and an MPE system would extract petroleum hydrocarbon-impacted soil vapor and groundwater from the subsurface for treatment, but they differ in the methods and level of vacuum applied to subsurface media. The primary difference is that with an MPE system, higher vacuums are induced and both groundwater and soil vapor are extracted through the same system.

The Existing Project Data Review and Design Data Gap Analysis (DGA) included as Appendix A to the EDR, included a discussion of previous remedial actions and pilot tests conducted at the site. A free product recovery, groundwater treatment, and vapor extraction system were installed at the site prior to 6 December 1989 by Chemical Processors, Inc., Environmental Services Division. Though SVE was a component of this system, operational details from this system are not expected to be representative of SVE conditions throughout the site as the former SVE system was installed within the UST excavation backfill.

Based on previous conversations with Ecology, an SVE pilot study was not able to be performed due to contracting and schedule issues. In lieu of performing a pilot study, an SVE system could be designed with the limited existing data but would need to utilize relatively conservative estimates of design parameters including, but not limited to, extraction well radius of influence (ROI), extraction vacuum and volumetric flow rate, and vapor mass loading. Groundwater is shallow across the site which limits the vacuum that can be applied without removal of significant volumes of water. A conservative approach for SVE system design would include installing additional extraction wells and associated subsurface piping and infrastructure for treating extracted vapor, resulting in increased system installation, operation, and maintenance costs.

The multiphase fluid recovery pilot test conducted in 2005 by Eco-Vac Services, Inc. of Woodstock, Georgia, provided data including vapor extraction rates, induced vacuum ROI, vapor mass loading, and total volumes of removed liquids, which can be used to design an MPE system for the site.

SVE with Groundwater Recirculation - Remedial Alternative 1 (RA1)

The SVE with groundwater recirculation component of the remedial design would begin with the construction of several onsite remediation wells (estimate of 17 new wells) to supplement existing multipurpose remediation/monitoring wells (estimate of 7 wells). The estimated 24 remediation wells and would be connected to the treatment system equipment. Twelve (12) of the wells would function as SVE wells and be connected via subsurface piping to above ground blower/vapor treatment equipment. The other twelve (12) wells would function as groundwater

Mr. Dale Myers, Washington State Department of Ecology November 21, 2023 Circle K 1461 Page 3

recirculation injection/extraction wells and be connected via subsurface piping to the groundwater injection equipment. The number of wells is based on an estimated ROI of 30 feet.

The SVE component of the system would be operated for approximately 2 years, until evaluation of extracted vapor monitoring results indicates that the concentration of volatile petroleum hydrocarbons (measured as GRO and BTEX) in soil gas has declined appreciably, and the VI pathway is no longer a potentially complete exposure pathway. After initial operation of the SVE system and removal of adequate GRO and BTEX from soil that could partition into soil vapor, further operation of SVE system may be periodic (i.e., pulsed) to help optimize its performance.

Following operation of the SVE system, the groundwater recirculation phase of remediation would begin. The initial step includes injection of a low-concentration surfactant solution to increase petroleum hydrocarbon recovery rates. This step would be followed by injection and recirculation of a combination of extracted groundwater and amendments (i.e., a cultured bacteria consortium of petroleum-degrading bacteria and macronutrients) into the target cleanup area to stimulate biodegradation of GRO and BTEX in the saturated zone (including smear zone soils). Groundwater recirculation operation is estimated to take approximately 5 years.

Operation of the SVE system followed by groundwater recirculation is estimated to occur for a total of approximately 7 years.

MPE - Remedial Alternative 2 (RA2)

As part of the MPE system installation, a combination of vertical and slanted (angled) wells would be installed (estimate of 6 total wells) at locations identified as most likely to reduce the concentrations of the contaminants of concern. Several existing remediation/monitoring wells (estimate of 7) would also be connected to the treatment system equipment. Monitoring and potential mitigation of sub-slab vapor concentrations would be achieved by installing sub-slab depressurization wells and vapor monitoring points in and around the existing onsite structures. Soil vapor and extracted groundwater would be treated by carbon adsorption using granular activated carbon (GAC) with a provision for the use of a thermal oxidizer to treat vapors during the startup phase of the project. An ROI of 20 feet was estimated for vapor and an ROI of 30 feet was estimated for groundwater.

Groundwater initially extracted from the system is expected to be discharged after treatment with GAC to the sanitary sewer. Once groundwater concentrations become nearly asymptotic and carbon usage has stabilized, surfactants would be used to increase hydrocarbon recovery rates. A few months after surfactant treatment has begun, bioremediation treatment would be implemented. This includes treating recovered groundwater with GAC, and adding oxygen

Mr. Dale Myers, Washington State Department of Ecology November 21, 2023 Circle K 1461 Page 4

and/or other electron acceptors, petroleum-degrading bacteria, and nutrients before reinjecting amended groundwater. MPE operation is expected to take approximately 5.5 years.

Cost Comparison

The design differences in the two remedial approaches discussed above produce differences in overall system costs, a main factor considered in the pre-design and design processes. Overall costs are influenced most heavily by components such as materials for extraction and injection well installations, groundwater amendments, and sampling effort. These differences are primarily driven by the difference in total number of remediation wells (24 wells for RA1 compared to 13 wells for RA2) and system operation time (7 years for RA1 versus 5.5 for RA2). Itemized cost estimate tables are presented in Attachments A and B. The following table provides a summary of the system construction cost, long-term operations and maintenance (O&M) costs, and total projected cost per remedial alternative.

| | RA1 - SVE with Groundwater Recirculation | RA2 - MPE |
|--------------------------|---|-------------|
| System Construction Cost | \$1,032,000 | \$813,200 |
| Long-Term O&M Cost | \$2,438,800 | \$2,381,500 |
| Total Estimate* | \$5,576,000 | \$5,146,000 |

*Total estimate includes construction report, O&M manuals, project coordination, and Washington state sales tax. Total estimate also includes the following scaling factors: Division 1 costs, contractor markup for subcontractors, contractor overhead and profit, estimate contingency, and escalation to the midpoint of construction.

The costs presented in this addendum include the following additions from the 2021 EDR: confirmation monitoring for both soil and groundwater, groundwater circulation system components and O&M (considered separately from SVE-related costs), and detailed planned reporting requirements and frequency.

The following line items were updated from the 2021 EDR to reflect current costs: remediation system operation costs (i.e., updated estimates for groundwater amendments), estimated effort and frequency for O&M activities, and sample quantity and lab analysis cost.

Alternatives Analysis and Chosen System

The alternatives analysis (Attachment C) conducted for the two systems indicates that MPE is the recommended alternative. The current benefit to cost ratio is greater for the installation of an MPE system, which has a lower probable cost by approximately \$430,000. Factors including

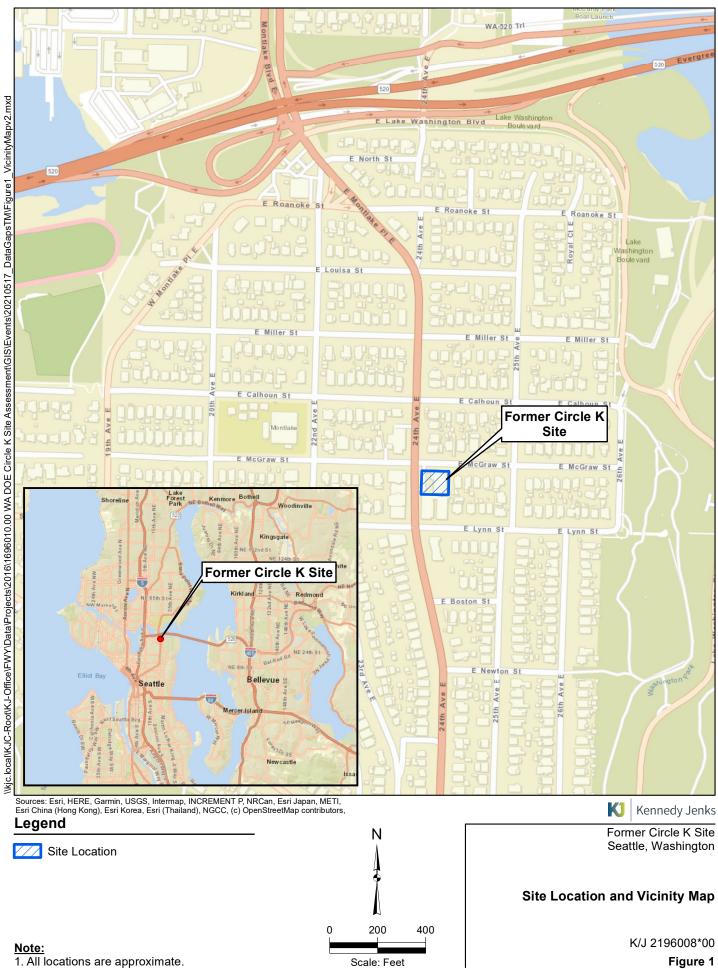

Mr. Dale Myers, Washington State Department of Ecology November 21, 2023 Circle K 1461 Page 5

additional infrastructure and a longer operation timeline increase the probable cost of the SVE with groundwater recirculation alternative, causing it to be less practical than an MPE system.

Washington State Department of Ecology

| | | ALTERNATIVE 1 SVE (plus Groundwater Recirculation) | ALTERNATIVE 2 MPE |
|---------------------------------------|--------------|---|---|
| Restoration Timeframe | 15% | 6 Ability to change flow paths may decrease amount of concentration rebound. Recirculation system expected to run for approximately 5 years, SVE system for approximately 2 years. | 6 Higher vacuums may lead to faster/easier cleanup of so expected to run for 5 years. |
| O&M | 15% | 7 SVE plus groundwater recirculation would have slightly more infrastructure than MPE due to the potential for additional pumps or wells needed. However, operationally, the recirculation system could allow for more flexibility in how the system would operate (e.g. which wells to inject into, changing flow paths). O&M on just the recirculation system would last longer than on the SVE system, simplifying O&M after SVE shutdown. | 6 MPE has less infrastructure. However, dealing with both could lead to additional mechanical issues compared to and one for SVE. Less concerned about how much wate the system since that is a feature of the system. O&M is blower) so is made simpler. Recirculation would still be allow flexibility in how the system would operate (e.g. wh flow paths), but slightly fewer wells would mean less flex |
| Protectiveness | 15% | 6 Both systems equally protective of VI and would reduce contaminant concentrations at the site. | 6 Both systems equally protective of VI and would reduce the site. |
| Permanence | 15% | 8 Ability to change flow paths may decrease amount of concentration rebound. | 7 Higher vacuums may lead to faster/easier cleanup of so |
| Long-Term Effectiveness | 10% | 7 Once contaminant mass is removed, effect is permanent. | 8 MPE may be more effective in unsaturated soils. Once of effect is permanent. |
| Short-Term Risks | 10% | 7 Remediation worker risk due to potential contact with impacted media during installation, operation, and maintenance. Moderate degree of risk to workers (contact with impacted media) and minimal risk to the community and environment (discharge of treated air and water). | 7 Remediation worker risk due to potential contact with im installation, operation, and maintenance. Moderate degr with impacted media) and minimal risk to the community treated air and water). |
| Implementability/ Constructability | 15% | 7 Installation between the systems would be similar, but may be slightly more complicated with SVE because of the access needed during implementation (due to number of wells). | 8 Installation between the systems would be similar, but n due to fewer wells being needed and less infrastructure |
| Public Concerns | 5% | 5 | 5 |
| Total Weight | | 6.8 | 6.7 |
| Estimated Co | | \$5.58 | \$5.15 |
| Benefi | t/Cost Ratio | 1.2 | 1.3 |
| | | | MPE is the recommended alter |

Notes:

Alternatives are ranked on a scale of 1 to 10 based on how each alternative satisfies the listed criteria (1 = does not meet criteria, 10 = meets criteria completely).

| soils in the vadose zone. System |
|--|
| oth water and vapor in one system to one system for groundwater ater would be collected through is only on one system (and e included in this alternative to which wells to inject into, changing lexibility in operation. |
| ce contaminant concentrations at |
| soils in the vadose zone. |
| e contaminant mass is removed, |
| impacted media during gree of risk to workers (contact hity and environment (discharge of |
| t may be slightly easier with MPE re (fewer pumps). |
