Site	Pasco Bulk Fuel Terminals Site
SVE	Soil vapor extraction
TCE	Trichloroethene (trichloroethylene)
TPH	Total petroleum hydrocarbons
μg/L	micrograms per liter

## 1.0 INTRODUCTION

This report presents the results of the November 2024 groundwater monitoring fieldwork conducted by WSP USA Inc. (WSP; formerly Golder Associates USA Inc. [Golder]) at the Pasco Bulk Fuel Terminals Site (the Site) in Pasco, Washington. A Site map is presented in Figure 1. This work was conducted in accordance with the Monitored Natural Attenuation (MNA) Performance Monitoring Plan (Golder 2019) in conjunction with the Sampling and Analysis Plan (SAP) contained within the Compliance Monitoring Plan (CMP) for the Site dated December 20, 2000 (Golder 2000).

Remedial actions conducted at the Site from 1999 through 2014 consisted primarily of in-situ air sparging (IAS) in combination with soil vapor extraction (SVE). Groundwater extraction and treatment ("pump-and-treat") was also used in some areas. During active remediation, major progress was made toward achieving cleanup across the Site. Based on SVE off-gas monitoring data, approximately 58,000 pounds of total petroleum hydrocarbons (TPH) were removed by IAS-SVE. The total TPH removal was greater because this estimate does not account for removal that occurred by pump-and-treat nor for in-situ biodegradation. TPH mass removal rates using IAS-SVE reached asymptotic levels; thus, IAS-SVE was no longer effective.

Under MNA, the group evaluated the Site risk and various alternatives to achieve Site closure (Golder 2013). The results of the evaluation indicated that MNA and institutional controls (institutional controls as described in the Cleanup Action Plan [Ecology 1999]) were protective of human health and the environment and were the preferred alternative for achieving groundwater cleanup levels throughout the Site. Ecology issued a decision letter dated September 19, 2018 (Ecology 2018) that indicated MNA as a remedial action was covered under the existing Consent Decree for the Site, such that MNA can be implemented at the Site without modifying the Consent Decree.

The MNA Performance Monitoring Plan (Golder 2019) was prepared to work in conjunction with the SAP and Quality Assurance Project Plan contained within the CMP (Golder 2000) to provide the scope, methods, and procedures that will occur to ensure natural attenuation is occurring, is effective and protective of human health and the environment and demonstrates compliance with Site cleanup standards. Groundwater monitoring conducted under the MNA Performance Monitoring Plan was started in June 2019.

#### 1.1 Field Work

The November 2024 groundwater monitoring was performed on November 12 and 13, 2024 and included the following activities:

- Groundwater monitoring was conducted on 16 groundwater-monitoring wells (MW-06, MW-08, MW-11A, MW-12, MW-13, MW-17, MW-18, MW-19, MW-20, MW-33, MW-34, MW-48, MW-49, MW-62R, MW-63, and MW-66).
- Water level measurements were taken in these wells, except for MW-48 and MW-49. These wells contain roots within them that obstruct a water level tape.
- Surface water sampling of the discharge from the oil-water separator (SEP-OUT) on the United States Army Corps of Engineers' (COE) drain. In accordance with the CMP (Golder 2000), the COE drain is only sampled when there has been no measurable rain during the four days prior to sample collection. This ensures that the sample collected is predominately associated with groundwater from the COE drain.

In accordance with the MNA Performance Monitoring Plan (Golder 2019), each well was analyzed for those indicator substances that remain above cleanup levels in that well. In addition, select monitoring wells were also analyzed for geochemical parameters - dissolved oxygen, nitrate, manganese, iron, sulfate, methane, redox potential (Eh), and alkalinity. Changes in these geochemical parameters can indicate that biodegradation is occurring. These changes can be evaluated over time within a well, or by comparing levels of these parameters in wells that are still impacted with indicator substances to wells that are located upgradient or in clean areas of the Site.

Positive evidence of biodegradation includes one or more of the following indicators:

- Depressed oxygen, nitrate, or sulfate levels in source area wells as compared to background wells
- Low Oxidation-Reduction Potential (i.e., reducing conditions) in source area wells as compared to background wells
- Higher iron (Fe2+), manganese (Mn2+), and methane in source area wells as compared to background wells

During performance monitoring, natural attenuation parameters are measured in two wells (MW-18 and MW-62R) that have been below cleanup levels for more than five years, and in a selection of wells that have relatively higher petroleum hydrocarbon concentrations (MW-08, MW-11A, MW-12, MW-33, MW-34, and MW-63). The testing of these wells allows for comparison of geochemical parameters in areas where contaminants are being biodegraded compared to clean areas of the Site.

## 1.2 Field Equipment

Wells were sampled using peristaltic pumps with dedicated high-density polyethylene (HDPE) and silicone tubing. During previous sampling events, HDPE tubing was placed in each well at a depth approximately halfway between the bottom of the well screen and the water level in the well. A summary of monitoring well completion data, including tubing depths for each well, is presented in Table 1.

The HDPE tubing was inserted into a short (< 0.5 foot) length of silicone tubing that was inserted into the peristaltic pump. An extra length of HDPE tubing was used to connect the silicon tubing to a flow-through cell. Each length of silicon tubing and HDPE sample tubing was used only once to avoid cross-contamination between wells, except for well-specific dedicated tubing. The flow-through cell consisted of a 2-inch-diameter acrylic cylinder with a capped bottom that was attached to a 5-gallon bucket. The flow-through cell had an inlet port near the bottom and another outlet port near the top. The sample tubing was connected to the bottom port, so the cell filled from the bottom and flowed out the top port into a purge water container. A multimeter (pH, temperature, specific conductance, dissolved oxygen, and Eh) was inserted into the flow cell from the top and was monitored every 3-5 minutes to determine when field parameters had stabilized in the purge water.

Once the well was purged and field parameters had stabilized, the tubing was disconnected from the flow cell and the groundwater samples were collected directly from the sample tubing. The flow cells were rinsed with deionized water between wells. The HDPE tubing dedicated to each well was capped and left hanging in the well by attaching it to the well cap using line. The thermos-type well caps were used to secure the well after sampling. Well monument covers were securely bolted.

## 1.3 Micropurging

Well purging was conducted following the "micropurging" procedure accepted by EPA and described in Groundwater Sampling Procedure Low Stress Purging and Sampling (EPA 1997). This procedure recommends an initial purging rate of 200 to 500 milliliters per minute (ml/min) and a sampling rate of 100 to 250 ml/min, while ensuring water level drawdown does not exceed 0.3 feet. This low-flow method minimizes well disturbances and therefore reduces turbidity, minimizes aeration of the groundwater during sample collection, and reduces the volume of purge water generated. In some cases, the well yield was insufficient to maintain a drawdown of less than 0.3 feet while continuously pumping at the minimal purge rate. Wells were considered sufficiently purged when field parameters remained stable for three consecutive measurements taken approximately 3 to 5 minutes apart. The field parameters were considered stable based on the following criteria:

- +/- 0.1 for pH
- +/- 3% for specific conductance
- +/- 10% for dissolved oxygen
- +/- 10% mV for Eh
- +/- 0.5 degree C for temperature

The stabilized field measurements for pH, temperature, specific conductance, dissolved oxygen, and Eh for each well at the time sampling was initiated are presented in Table 2.

## 1.4 Purge Water

Purge water was collected in 5-gallon containers at each sampling location. The purge water was then transferred into the 55-gallon drums for subsequent treatment and disposal.

#### 2.0 DATA SUMMARY

#### 2.1 Water Level Data

Water level data collected during November 2024 are presented in Figure 2 and Table 3.

## 2.2 Analytical Results

Groundwater samples were stored in coolers with ice until retrieved by Eurofins, an Ecology-certified laboratory located in Tacoma, Washington. Chain-of-custody procedures were followed. A complete tabulation of analytical results is provided in Appendix A.

All analytical data were subject to a data validation review. Data validation was conducted in accordance with the EPA Contract Laboratory Program, National Functional Guidelines for Organic and Inorganic Data Review (EPA 2017a, b). Data reporting qualifiers are included with the analytical results in Appendix A.

## 2.3 Monitored Natural Attenuation Performance Assessment and Cleanup Determination

## 2.3.1 MNA Performance Assessment

Table 4 provides a summary of the geochemical analytical results obtained from the two background wells and from the six higher concentration wells or "impacted wells". Evaluation of the results confirms that biodegradation is occurring in the remaining higher concentration areas. Evidence of biodegradation includes the following:

- Alkalinity is generally higher in the impacted wells, which is caused by carbon dioxide produced during biodegradation.
- Oxygen, nitrate, and sulfate concentrations are lower in the impacted wells as these electron acceptors are used up in the biodegradation process.
- Reduced forms of iron and manganese concentrations are higher in the impacted wells, due to the reduction of forms Fe3+ and Mn4+.
- Methane concentrations are significantly higher in the impacted wells as methane is produced during biodegradation under anaerobic conditions. Methane was not detected above the reporting limit in the clean wells.

The above noted geochemical markers of biodegradation were more pronounced in some of the higher concentration wells, but all the impacted wells tested for geochemical parameters had indications that contaminant biodegradation is occurring in those wells.

Trend graphs of the analytical results since the start of monitored natural attenuation in 2014 are presented in Appendix B. Evaluation of trend graphs indicates the following:

- Area 2 Arsenic is above cleanup levels in MW-06, MW-12, MW-13, and MW-63, with a long-term stable to slightly decreasing trend. Benzene is above cleanup level in MW-63, with a slight long-term decreasing trend. A more pronounced decreasing trend in benzene concentration has been occurring in well MW-12, and the November 2024 concentration was below the cleanup level. TPH is above cleanup level in MW-12 with a slight long-term decreasing trend since 2014. TPH has been below or near the cleanup level in MW-63 since 2019.
- Area 3 Arsenic has been near the cleanup level in MW-17 since 2020, with no apparent recent trend.
- Area 4 Arsenic and TPH are above the cleanup level in MW-11A, with no apparent recent trend.
- Area 6 TPH is above the cleanup level in MW-08. The TPH concentration reported in MW-19 was below the cleanup level in 2023 but was slightly above the cleanup level during this sampling round. Arsenic is above the cleanup level in MW-19. Concentrations of arsenic and TPH are steady to slightly decreasing in MW-19, and TPH concentrations have no apparent long-term trend in MW-08.
- Area 7 Tetrachloroethene (PCE) is above the cleanup level in MW-20 and MW-49. Trichloroethene (TCE) has been below the cleanup level in MW-49 for the last four sampling rounds. TPH is above the cleanup level in MW-33 and MW-34 and has a slight long-term decreasing trend. Arsenic is above the cleanup level in MW-34 with no apparent long-term trend.

Area 8 – Arsenic concentrations have been decreasing in MW-48 in the long-term and have been fluctuating around the cleanup level since 2018. Arsenic concentrations in MW-48 were below the cleanup level in three of the last four sampling rounds.

COE Drain Oil-Water Separator - Starting with the October 2019 sampling round, the COE Drain sample is collected from the oil-water separator discharge pipe. During previous rounds, samples were collected from inside the concrete vault of the oil-water separator. Samples collected directly from the end of the discharge pipe of the oil-water separator are safer for sampling personnel and are more representative of the actual concentration contained in the water discharged from the COE Drain oil-water separator. PCE has historically been detected slightly above the 1.75 micrograms per liter (μg/L) cleanup level, however, PCE has been below the drinking water Maximum Contaminant Limit (MCL) of 5 μg/L since October 2008. PCE concentrations have been decreasing since 2015. The concentration of PCE detected during two of the last four sampling rounds was below the cleanup level.

## 2.3.2 Cleanup Determination

Under the MNA Performance Monitoring Plan, groundwater cleanup for each Remediation Area will be determined as follows:

- a) Within a Remediation Area, if any single well has not exceeded cleanup levels for a particular indicator substance for two consecutive annual monitoring events, then the performance monitoring for that contaminant in that well can be suspended.
- b) A well that has met Condition "a" can move into confirmational monitoring. Once in confirmational monitoring, if the indicator substance remains below its cleanup level for two consecutive confirmational sampling rounds, then that well will be considered clean for that substance. Monitoring events will not occur more frequently than semi-annually.

When all wells within a Remediation Area have met Condition "b" for all indicator substances, then the Remediation Area will have met groundwater cleanup levels.

To assist in evaluating compliance with the above criteria, Table 5 presents the analytical results for each indicator substance detected during the last four sampling events and is sorted by cleanup area.

TCE in Remediation Area 7 well MW-49 has been below cleanup level for four consecutive rounds. TCE will no longer be analyzed in samples collected from well MW-49. No other changes to the Performance Monitoring Plan are indicated. During 2025, annual sampling will continue in accordance with the Performance Monitoring Plan (Golder 2019).
