SUMMARY

This summary is not intended as a stand-alone document and must be evaluated in context with the entire document.

On behalf of the Port of Ridgefield (the Port), Maul Foster & Alongi, Inc. prepared this remedial investigation (RI) and feasibility study (FS) report for the former Pacific Wood Treating Co. (PWT) site in Ridgefield, Washington (see Figure ES-1). PWT operated a wood-treating facility from 1963 to 1993 at the Port's Lake River Industrial Site (LRIS). This RI/FS report was prepared under the authority of Agreed Order No. 01TCPSR-3119 between the Port and the Washington State Department of Ecology (Ecology) to satisfy the requirements of the Model Toxics Control Act (MTCA) and sediment management standards (SMS) and addresses the substantive requirements of Washington Administrative Code (WAC) 173-340, -350, and -360 (MTCA) and WAC 173-204 (SMS). This final report addresses comments provided by Ecology on a draft version submitted on March 16, 2012, and includes additional investigation and reporting completed since the draft version was submitted.

The purpose of this report is to summarize RI activities on the LRIS and adjacent off-property areas, describe cleanup activities already implemented and under way on the LRIS, develop cleanup levels (CULs), evaluate the feasibility of remediation alternatives, and describe preferred remedies. The areas addressed by the RI/FS include the LRIS, adjacent upland off-property areas (i.e., upland areas not part of the LRIS), and nearby surface water bodies Lake River and Carty Lake (see Figure ES-2). For purposes of this RI/FS report, the "Site" is defined as these four areas.

Since 1985, multiple investigations have been conducted on and adjacent to the LRIS property to characterize the impacts associated with historical PWT operations; these investigations included collection of soil samples on the LRIS and upland off-property, groundwater samples on the LRIS and the nearby Ridgefield National Wildlife Refuge (RNWR), and sediment samples in Lake River and Carty Lake.

The Port has conducted interim actions on the LRIS since 1996, with Ecology oversight and approval. The interim actions have included initial source removal after PWT vacated the property, an emergency action that involved steam-enhanced remediation (SER) focused on removing mobile product in the subsurface, and more recent interim actions to address soil impacts. Former PWT operations impacted soil, groundwater, and sediment with wood-treating-related chemicals including metals, phenols (including pentachlorophenol [PCP]), polycyclic aromatic hydrocarbons (PAHs), petroleum hydrocarbons, volatile organic compounds, and/or chlorinated dibenzo-p-dioxins and dibenzofurans (collectively referred to in the report as dioxins). Recently completed interim actions and those under way, with completion slated for 2013, have focused on removal of highly impacted soil and capping remaining above-CUL soil for protection of human health (i.e., workers and potential future recreationists) and the environment.

Interim actions also include source control actions. Historically, stormwater discharge has been a mechanism for transporting impacts in soil on the LRIS property to Lake River. The soil cap will eliminate the mobilization of impacts in soil via stormwater; further, the interim actions for 2012 included completing replacement of the LRIS stormwater system.

The SER system operated as an emergency/interim action near the former tank farm where a 4-acre plume of nonaqueous-phase liquid was present. The SER greatly decreased concentrations of wood-treating compounds in groundwater; the nature and extent of groundwater impacts have been defined, and concentration trends are stable or declining. Groundwater modeling has shown that chemicals are not discharging to surface water at concentrations that exceed levels protective of beneficial uses of surface water. Point of compliance sampling will be conducted after remedial actions have been completed in order to confirm concentration trends in groundwater.

Characterization has been conducted for the upland off-property, which includes properties owned by the Port (Port-owned properties) and other properties (non-Port-owned properties). Characterization for the Port-owned properties is complete, while further characterization activities may be conducted for the non-Port-owned properties; a brief summary is provided below. Lake River and Carty Lake characterization has been completed. A summary of the nature and extent of impacts, exposure scenarios, and the preferred remedial alternative for these areas is presented below.

UPLAND OFF-PROPERTY

The upland off-property area includes the Port-owned properties (the undeveloped Railroad Avenue properties, the Port-owned marina, and the Port-owned proposed overpass property) and the non-Port-owned properties (a residential area, RNWR soils just north of Cell 4, and a privately owned marina property) (see Figure ES-2).

Port-owned properties: Wood-treatment chemicals associated with historical PWT operations were largely undetected or occurred below levels expected to cause unacceptable human health or ecological risk. Dioxins were detected above levels protective of human health and ecological receptors. Incidental ingestion of dioxins in soil was identified as the most significant potential exposure pathway for humans. Exposure to ecological receptors is limited, given the small size and lack of quality habitat in this area; however, ecological receptor direct contact and secondary ingestion are considered complete pathways. To address potential human health and ecological risk associated with direct or indirect exposure to impacts in soil, the following primary actions are recommended:

- A 2-foot cap for the Port Railroad Avenue properties. The extent of the cap would include a portion of the Port-owned property and the City of Ridgefield right-of-way, approximately 0.55 acre. The cap would be monitored annually.
- Most of the Port marina property has been capped with asphalt. In addition, a narrow strip of soil between the asphalt on the Port marina property and Cell 3 was capped with polypropylene geotextile fabric and soil as part of LRIS interim actions. The cap would be monitored.

- The proposed overpass area will be covered with a cap consistent with LRIS capping options, limiting potential exposure. If soil is excavated in this area during construction, a soil management plan will be required.

Non-Port-owned properties: Surface soil near the LRIS is generally impacted uniformly with dioxins at concentrations that marginally exceed the MTCA Method B CUL, but concentrations are well below the MTCA Method C CUL. RNWR soils are well below MTCA Method B CULs. The proximate source(s) of dioxins are not well established. Residential or worker exposure to dioxins in surface soil may occur through direct contact with impacted surface soil. No wood-treating chemicals were detected above MTCA default CULs in non-Port-owned properties. A terrestrial ecological evaluation conducted for the upland off-property area indicates that adverse ecological impacts are not expected for non-Port-owned properties. Soils have been characterized in rights-of-way in the residential area, and other potential exposure points (e.g., yards) have not been characterized. Human health CULs and a feasibility analysis are therefore not being developed at this time.

LAKE RIVER

Lake River is adjacent to and west of the LRIS and is a relatively shallow, slow-velocity river that is frequented by recreationists and is habitat to aquatic animals, including special-status salmonids, waterbirds such as the great blue heron, and aquatic mammals such as the river otter. Sediment is impacted with phenols (including PCP), PAHs, and dioxins. Phenol and PAH impacts are limited and colocated with elevated dioxin concentrations; thus, dioxins are selected as indicator hazardous substances. The highest concentrations were adjacent to LRIS stormwater outfalls and were generally limited in vertical extent to the top foot or two of sediment. Human exposure to impacts in sediment may occur through direct contact or consumption of organisms (e.g., fish) that have accumulated chemicals in tissue. Ecological exposure is likely to result from uptake of chemicals in sediment or ingestion of chemicals in aquatic prey. To address potential human health and ecological risk associated with direct or indirect exposure to impacts in sediment, the following primary actions are recommended:

- Dredge removal of Lake River sediment with dioxin toxicity equivalent exceeding 30 nanograms per kilogram. Dredging would also remove other contaminants exceeding screening criteria.
- Employment of enhanced natural recovery in the remediation area.
- Long-term monitoring to assess natural recovery of sediment.
- Application of bank armor to stabilize the lower portions of the bank below the ordinary high-water mark (this is not within the scope of the upland interim remedial actions); this would also protect against direct contact with and erosion of bank soil.

Implementation of this remedy, along with natural attenuation, is expected to achieve site-specific CULs, and contaminated sediment would be permanently removed and would not be available for potential future exposure or transport.

CARTY LAKE

Carty Lake is a 52-acre, ponded wetland located in the RNWR. The lake provides habitat for plants, benthic invertebrates, fish, mammals, and raptors, and is not readily accessed by visitors. Sediment in Carty Lake is impacted with arsenic, chromium, PCP, and dioxins. Highly elevated chemical concentrations are limited to the southern portion of the lake. Direct human exposure to impacts in sediment likely is limited to potential future U.S. Fish and Wildlife Service restoration workers. Tribal members might wish to reinstitute harvest of the wapato plant at Carty Lake; however, a CUL has not yet been developed for this scenario. Although fishing takes place only rarely in the lake, human consumption of fish was evaluated. Ecological exposure scenarios include uptake of chemicals in sediment and ingestion of chemicals in aquatic prey. To address potential human health and ecological risk associated with direct or indirect exposure to impacts in sediment, the following primary actions are recommended:

- Dredging and disposal of approximately 5,650 cubic yards (CY) of lake sediment above ecological CULs in the southern portion of the lake
- Placement of approximately 2,700 CY of sand for a residuals cap in a 6- to 12-inch-thick layer over dredged areas
- Long-term monitoring to assess natural recovery of sediment
- Institutional controls, including advisories on fish consumption, to protect potential fishers

Implementation of this remedy would remove sediment with concentrations of chemicals above CULs protective of ecological receptors. The highest concentrations of chemicals in sediment would be permanently removed and would not be available for potential future exposure or transport. Human health would be protected through institutional controls limiting consumption of fish from Carty Lake.

1 INTRODUCTION

On behalf of the Port of Ridgefield (the Port), Maul Foster & Alongi, Inc. (MFA) prepared this remedial investigation (RI) and feasibility study (FS) report for the former Pacific Wood Treating Co. (PWT) site in Ridgefield, Washington (see Figure 1-1). PWT operated a wood-treating facility from 1963 to 1993 at the Port's Lake River Industrial Site (LRIS). This RI/FS report was prepared under the authority of Agreed Order No. 01TCPSR-3119 (the Order) between the Port and the Washington State Department of Ecology (Ecology) to satisfy the requirements of the Model Toxics Control Act (MTCA) and sediment management standards (SMS) and addresses the substantive requirements of Washington Administrative Code (WAC) 173-340, -350, and -360 (MTCA) and WAC 173-204 (SMS).

The purpose of this report is to summarize RI activities on the LRIS and off-property areas, describe cleanup activities already implemented and under way on the LRIS, develop cleanup levels (CULs), evaluate the feasibility of remediation alternatives, and describe preferred remedies. This final report takes into account comments provided by Ecology on a draft version submitted on March 16, 2012. In addition, this report includes additional investigation and reporting completed since the draft version was submitted to Ecology.

1.1 Definition of Site

The areas addressed by this RI/FS include the LRIS, upland off-property areas, and nearby surface water bodies Lake River and Carty Lake (see Figure 1-2). The areas are described below:

- LRIS—this area consists of property formerly used by PWT, which operated a wood-treating facility, and includes four designated areas referred to in the Order as Cells 1, 2, 3, and 4. Soil and groundwater on the LRIS were impacted by PWT's historical operations.
- Upland off-property area—this consists of an upland area of investigation north, east, and south of the LRIS (i.e., upland areas not part of the LRIS). The area includes properties owned by the Port and other areas (residential area, Ridgefield National Wildlife Refuge [RNWR] soil, and a privately owned marina). The sources of chemicals in surface soil in the off-property are not well established.
- Lake River—a river on the western property boundary of the LRIS. Sediment offshore of the LRIS in Lake River has been impacted by wood-treating-related chemicals.
- Carty Lake—a lake in the RNWR north and west of the LRIS. Sediment in Carty Lake just north of the LRIS has been impacted by wood-treating-related chemicals.

For purposes of this RI/FS report, the "Site" is defined as the areas described above.

1.2 Regulatory Framework

This report completes the RI/FS for the Site, and incorporates the RI/FS work completed for the LRIS, surrounding upland off-property areas, Carty Lake, and Lake River. This RI/FS report was written to fulfill the requirements in Section IV, Item 8 of the Order. The report is designed to meet the requirements of MTCA (WAC 173-340, -350, and -360) and SMS (WAC 173-204) for conducting an RI/FS.

1.3 Report Organization

The report is organized as follows:

- Section 2 provides background information for the Site, including setting, geology, and hydrogeology. Previous investigations of each of the areas are summarized, and current and future land uses are identified.
- Section 3 summarizes the nature and extent of impacts and identifies indicator hazardous substances (IHSs).
- Section 4 summarizes interim remedial actions conducted, as well as approved actions that are under way on the LRIS.
- Section 5 presents a conceptual site model (CSM) identifying potentially complete exposure pathways by identifying sources, transport mechanisms, exposure media, and potential receptors on the Site.
- Section 6 summarizes CULs previously identified for the LRIS and describes development of CULs for the upland off-property areas (Port-owned properties and non-Port-owned properties) and Lake River and Carty Lake. Points of compliance (POCs) are identified for each area and matrix.
- Section 7 summarizes the feasibility analyses conducted and previously submitted to Ecology for remedy of soil and groundwater on the LRIS.
- Section 8 is the feasibility analysis for remedy of soil on the Port-owned properties.
- Section 9 is the feasibility analysis for remedy of Lake River sediments.
- Section 10 is the feasibility analysis for remedy of Carty Lake sediments.
- Section 11 identifies the selected remedial action alternatives for the LRIS approved by Ecology and describes the preferred remedial action alternatives for the Port-owned properties and for Lake River and Carty Lake.

2 BACKGROUND

This section presents a description of the LRIS operational history, the setting (see Figure 1-2), a summary of previous investigations and cleanup actions, environmental characteristics, and current and future land uses.

2.1 LRIS History

The approximately 40-acre LRIS is the former location of the PWT facility. PWT's operations involved pressure-treating wood products with oil-based treatment solutions containing creosote, pentachlorophenol (PCP), and water-based mixtures of copper, chromium, arsenic, and/or zinc.

The Port owns the LRIS (note: 2.57 acres in Cell 3 previously owned by Union Pacific Railroad [UPRR] was recently acquired by the Port), which PWT leased from approximately 1963 to 1993. PWT filed for bankruptcy in 1993 and abandoned the LRIS. The Port has established office spaces on the LRIS and manages the property. The LRIS is divided into four areas designated in the Order as cells (see Figure 2-1). The historical uses of each of the cells are described below.

Cells 1 and 2 were vacant or used for farmland before industrial use by PWT. Cell 1 contained the PWT tank farm, the retort area, and a boiler room (see Figure 2-1). PCP was normally stored in the tank farm in Cell 1 as a 40 percent concentrate in "P9 oil." The P9 oil consisted of diesel and about 10 percent long-chain alcohols and ketones. When used, the PCP concentrate was typically mixed with additional P9 oil, or occasionally with mineral spirits. PWT also used copper naphthenate as an alternative to PCP. Other wood-treating chemicals used by PWT include Woodgard™ and Fyrgard™. Woodgard consists of boric acid and paraffin wax in hexylene glycol. Fyrgard consists of ammonium phosphate, ammonium sulfate, boric acid, and borax in a water-based carrier.

Cell 2 was used by PWT for wood-manufacturing operations, and also contained other features such as PWT's wastewater treatment plant (WWTP) and the concrete pond stormwater feature. Before the 1980s, the concrete pond was used to trap and collect spills that had entered the stormwater system. In the 1980s, the WWTP was constructed and used to treat wastewater generated by PWT. The WWTP was operated until 1993, when PWT abandoned its operations. The WWTP was demolished by the Port, with Ecology's oversight.

Before PWT's operations, the area now designated as Cell 3 was used as part of general shingle and sawmill operations. PWT stored treated poles and dimensional lumber throughout Cell 3, which it also referred to as the south pole yard (SPY) (see Figure 2-1). Until 1988, PWT allowed preservative to drip directly onto the ground. In 1988, PWT installed a drip trough in Cell 3 as a step toward removing excess preservative from poles before their placement in Cell 3 (see Figure 2-1).

Before PWT's operations, the area now designated as Cell 4 was used for farming. PWT used Cell 4 to store untreated wood and operated a peeler, to debark poles, from approximately 1966 to 1993.

Transportation of poles for treatment between Cell 4 and the rest of the LRIS most likely caused incidental tracking of wood-treating chemicals into Cell 4.

2.2 Setting

2.2.1 LRIS

The physical address of the LRIS is 111 West Division Street, Ridgefield, Washington, which is within the Ridgefield city limits. It is located in section 24, township 4 north, range 1 west, Willamette Meridian (see Figure 1-1). The LRIS is bordered by the RNWR to the north, and by the Burlington Northern-Santa Fe (BNSF) railroad tracks and the City of Ridgefield's (City) WWTP to the east. The BNSF railroad tracks separate the LRIS from a residential area. Lake River and the RNWR border the LRIS to the west, with the Port's boat launch and associated parking and Mill Street to the south. South of Mill Street is McCuddy's Marina and the Port-owned proposed overpass property. Figure 1-2 shows the LRIS and vicinity.

The Port owns the LRIS property, with the exception of a portion of the City's WWTP that was historically part of the LRIS and that falls within the Cell 2 boundary (see Figure 1-2).

The LRIS is relatively flat. Stormwater either infiltrates the soil or discharges to Lake River through outfalls.

2.2.2 Upland Off-Property

The upland off-property area is adjacent to the LRIS (see Figure 1-2). The upland off-property area includes Port-owned properties and other properties not owned by the Port. The off-property investigation area comprises the following areas:

- Port Railroad Avenue properties (east of the LRIS): The Port owns two parcels oriented north-south and located along Railroad Avenue just east of Cell 3 of the LRIS. These properties are upgradient of the LRIS and are undeveloped at this time.
- Port marina property (south of the LRIS): The property immediately south of the LRIS includes the Port-owned boat launch and parking area.
- Port proposed overpass property (south of LRIS): The 1.4-acre overpass area was formerly part of McCuddy's Marina and includes the footprint of a proposed overpass development.
- McCuddy's Marina (south of the LRIS): The approximately 5.3-acre, privately owned McCuddy's Marina property is located at 5 West Mill Street. McCuddy's Ridgefield Marina, the current operator, also leases approximately 11.04 acres in Lake River from the Washington State Department of Natural Resources (DNR).
- RNWR property (north of the LRIS): Three soil samples were collected along an east-west transect just north of Cell 4 in the RNWR to better define contaminant extent (see Section 3.2.2.2). This area is zoned parks/open space.

- Residential areas (east of the LRIS): The remaining off-property area east of the LRIS is zoned low-density residential and is upgradient of the LRIS. For purposes of this RI/FS report, the residential off-property area is defined as the area in which samples were collected as required by Ecology and is bounded as follows: the west boundary extends along Railroad Avenue from the northern portion of Cell 4 to the southern portion of Cell 3 on Mill Street; the eastern boundary runs along Main Avenue.

The upland off-property setting is shown on Figure 2-2. As shown, except for the RNWR property, there is substantial development and minimal viable ecological habitat in the upland off-property area.

2.2.3 Lake River

The lower Columbia River extends 146 river miles from Bonneville Dam to the Pacific Ocean. Elongated islands frequently divide the Columbia River and form sloughs, side channels, and adjacent lakes. Lake River is a side channel of the Columbia River and lies within the lower Columbia River west of Ridgefield, Washington, near the confluence of the Columbia River and the Lewis River. The National Wetlands Inventory has classified Lake River as a riverine, tidal, unconsolidated bottom, permanent tidal habitat.

Lake River is a tidally influenced, 11-mile-long channel and is hydraulically connected at its mouth to the Columbia River, through Bachelor Island Slough approximately 1 mile upstream of the mouth, and through a tide gate/flushing structure along the western shoreline of Vancouver Lake. It originates at Vancouver Lake in Vancouver, WA, to the south, runs parallel to the Columbia River, and merges with the Columbia at the northern tip of Bachelor Island (see Figure 2-3).

Sections of the RNWR border the entire length of Lake River to the west. Lake River is slow moving. It varies in width from approximately 100 feet to over 300 feet, and averages 10 feet deep or less. Where it is adjacent to the LRIS, Lake River is approximately 300 feet wide. Generally, steep banks occur on both sides and there is currently no emergent vegetation. Armoring and mature vegetation dominate the shoreline along the western side of the LRIS. In-water and overwater structures, including the Port's pump house, several piles, and a public access float dock, are located along the shoreline of the LRIS (Anchor QEA, LLC [Anchor] and MFA, 2011).

Based on available information, maintenance dredging of Lake River by the U.S. Army Corps of Engineers (COE) was last conducted in 1970 (Anchor and MFA, 2011). See Figure 2-3 for the approximate COE 1970 project boundary; the COE is authorized to dredge a channel to a width of approximately 100 feet and a depth of 6 feet, and typically dredges 2 additional feet to account for refill. There are no plans for COE dredge activities in Lake River in the near future; however, future dredging, if proposed by the COE, would need to take into account any remedial action(s) completed in Lake River.

2.2.4 Carty Lake

Carty Lake is a 52-acre, ponded wetland located in the RNWR Carty Unit (see Figure 2-3). The Carty Unit "lowlands" are immediately north of LRIS Cell 2 and west of Cell 4. Carty Lake is bordered by Lake River to the west, Gee Creek to the north, and BNSF railroad tracks to the east. During the rainy season, Gee Creek and Carty Lake can be hydraulically connected at the lake's northern end. During most of the year, Carty Lake has no outlet. Water levels in Carty Lake vary seasonally, and generally are higher during winter and spring and lower during summer and fall. The National Wetlands Inventory has classified Carty Lake as palustrine, unconsolidated bottom, permanent nontidal wetland, and Carty Lake contains Washington State-designated priority palustrine habitat.

2.3 Previous Investigations

Since 1985, multiple investigations have been conducted on and off the LRIS property to characterize the impacts associated with historical PWT operations. Previous investigations conducted on the LRIS, on upland off-property, in Lake River, and in Carty Lake are described in the sections below. Drawing 1 displays sample and monitoring well locations.

2.3.1 LRIS

Historical investigations at the LRIS include several groundwater and hydrogeologic evaluations; a Resource Conservation and Recovery Act (RCRA) preliminary assessment that identified solid waste management units and areas of concern; sitewide evaluations of potential source areas at locations previously identified as areas of concern (including the tank farm area, the retort/drip pad area, the drip trough, and the concrete pond and piping system); and a focused investigation and risk assessment (RA) in the area of the City's WWTP expansion in Cell 2. A RCRA facility investigation (RFI) was initiated for Cell 3. Because PWT filed for bankruptcy, the RFI was not completed.

The historical investigations in Cells 1, 2, 3, and 4 have been conducted by multiple parties on behalf of PWT since the mid-1980s and are described in detail in the 2004 work plan (MFA, 2004, Vols. I, II, and III). The Port has also completed RI/FSs for each cell. The consultant reports are summarized below.

- In 1985 and 1987, Sweet Edwards & Associates (SEA), on behalf of PWT, conducted a groundwater evaluation on and near the LRIS (SEA, 1986, 1987).
- In 1990, Ecology & Environment (E&E), on behalf of the U.S. Environmental Protection Agency (USEPA), conducted a preliminary assessment on the PWT facility (E&E, 1991).
- In 1991, Hart Crowser conducted site characterization on behalf of the USEPA (Hart Crowser, 1991).
- In 1993, Kleinfelder, on behalf of PWT, conducted site characterization throughout the LRIS (Kleinfelder, 1993).
- In 1995, E&E conducted site characterization throughout the LRIS for the USEPA (E&E, 1996).

- From 1997 through 2002, on behalf of the Port, MFA (note that all work completed by MFA was on behalf of the Port) conducted site characterization; the data were included in the Ecology-approved 2004 work plan for Cells 1, 2, and 4 (MFA, 2004, Vol. I).
- In 2007, MFA conducted an RI/RA for Cell 3 (MFA, 2007). Ecology approved this document by e-mail (Ecology, 2008a).
- In 2010, MFA conducted an RI/FS for Cell 4 (MFA, 2010e). Ecology approved the document (Ecology, 2010b).
- In 2010, MFA finalized a terrestrial ecological evaluation (TEE) for the former PWT site and submitted it to Ecology (MFA, 2010a). Ecology approved the TEE for the LRIS (Ecology, 2010a).
- In 2011, MFA completed an FS for Cell 3 (MFA, 2011c), which incorporated Ecology comments on the previous draft version.
- In 2011, MFA prepared a draft RI/FS report for Cells 1 and 2 and submitted it to Ecology (MFA, 2011a). Partial comments were provided in a meeting with Ecology; however, the report is awaiting final comments from Ecology before completion. The previously provided comments have been incorporated into this final RI/FS report.
- In 2011, MFA submitted an evaluation of the steam-enhanced remediation (SER) system and recommended discontinuation of the system (MFA, 2011d). Ecology provided a letter approving discontinuation of the SER system (Ecology, 2011b).
- In 2012, the Port and Ecology prepared a final closure plan for the SER system (Port and Ecology, 2012). The certification of clean closure for the SER system is provided as Appendix A.
- In 2012, MFA submitted a final groundwater summary report, including a groundwater monitoring plan, based on data collected and analyzed through August 2011 (MFA, 2012c). Ecology approved the report (Ecology, 2012a).

All work performed by MFA for the Port has been conducted under Ecology's oversight and consistent with the Order. The data generated during the abovementioned investigations are evaluated in this RI/FS report. Over 2,000 soil samples were collected at over 700 locations on the LRIS. Eighty-five groundwater monitoring wells have been monitored and over 200 reconnaissance groundwater samples have been collected. Sampling methodologies and results, including review of data quality, were previously submitted to Ecology in the reports identified above. Soil and groundwater samples recently collected and analyzed (November 2011) after the SER system was shut down are presented in this report. The November 2011 sample methodologies, data quality, and results are presented in Sections 3 and 4.

2.3.2 Upland Off-Property

A total of 30 primary surface soil samples were collected in the upland off-property to characterize the off-property extent of polycyclic aromatic hydrocarbons (PAHs), PCP, arsenic, chromium, copper, zinc, and chlorinated dibenzo-p-dioxins and dibenzofurans (dioxins). One sample (SS-6) was collected in the off-property Port marina area in July 2008 as part of LRIS RI characterization. In February 2009, three surface soil samples were collected north of the LRIS Cell 4, on RNWR property. In June, August, and September 2010, off-property surface soil sampling in the Port Railroad Avenue and residential areas was conducted at the request of Ecology to evaluate any potential off-site impacts of PAHs, PCP, arsenic, chromium, copper, zinc, and dioxins; 12 samples with one duplicate were collected (MFA, 2010b,d). Ecology required additional off-property surface soil sampling for dioxins, and 14 additional samples were collected in May 2011 in residential areas, McCuddy's Marina, and the proposed overpass property (MFA, 2011e). Data were evaluated relative to potential risks to terrestrial ecological receptors, and in 2012 MFA submitted a final off-property TEE to Ecology (see Appendix B). Ecology approved the off-property TEE (Ecology, 2012b), and additional composite soil sampling was conducted at eight locations in September 2012 from residential areas, McCuddy's Marina, and the proposed overpass property to characterize potential for unacceptable risk to ecological receptors due to exposure to dioxins in soil (see Appendix B for the supplemental TEE).

2.3.3 Lake River

Historical investigations of Lake River include the following: In 1991, Foster, Drake, and Farlow (1999) sampled dioxins in carp, crayfish, and sediment collected at Lake River near the LRIS (also see Buck, 2004); an RFI conducted by Kleinfelder (1993) documented the relationship between on-property contaminants and sediment and water samples in and around surface water outfalls in Lake River; a study conducted for the USEPA in 1996 examined potential contaminant migration to Lake River (E&E, 1996); in 1999, the U.S. Fish and Wildlife Service (USFWS) collected sediment and fish tissue samples in Lake River (Buck, 2000); and in 2000, MFA collected sediment samples at three Lake River outfalls (MFA, 2002).

In April 2010, Anchor and MFA collected 30 surface sediment and 19 subsurface sediment samples from stations in Lake River in areas adjacent to Cell 2 and Cell 3 as part of the sediment RI. Sample locations were identified to confirm or update the understanding of sediment impacts, given historical sampling; define the vertical and lateral extent of sediment impacts; evaluate natural background conditions of dioxins in sediment; and characterize potential upstream contributions of impacts from a City stormwater outfall.

In the 2010 work, surface sediment samples were collected using manual and Van Veen methodologies; subsurface sediment sampling was performed using a vibratory core sampler (vibracore). Chemical testing included testing for conventionals, semivolatile organic compounds (SVOCs), and metals, as well as selective testing for polychlorinated biphenyls, diesel-range petroleum hydrocarbons, and dioxins. Grain size was also tested at each station. Results were reported in the sediment RI (Anchor and MFA, 2011), which was subsequently approved by Ecology (Ecology, 2011a).

2.3.4 Carty Lake

Historical investigations of Carty Lake include the following: an RFI conducted by Kleinfelder (1993) that documented the relationship between on-property contaminants and sediment and water samples in Carty Lake; a study conducted for the USEPA in 1996 that concluded that contaminants originating from the LRIS had migrated off site and into Carty Lake (E&E, 1996); and in 1999, collection by the USFWS of sediment and fish tissue samples from Carty Lake (Buck, 2000).

In April 2010, as part of the sediment RI, Anchor collected eight surface sediment and seven subsurface sediment samples from stations in Carty Lake in areas adjacent to Cell 2 and Cell 4 of the LRIS. Sediment samples were collected using manual (e.g., hand auger) methodologies. Chemical testing included testing for conventionals, SVOCs, metals, dioxins, and selected diesel-range petroleum hydrocarbons. Grain size was also tested in surface samples and selected subsurface samples. Results were reported in the sediment RI data memorandum (Anchor and MFA, 2011), which was subsequently approved by Ecology.

In September 2011, MFA conducted additional sampling in Carty Lake to further characterize dioxin impacts in sediment. Surface sediment samples were collected at eight locations in Carty Lake, and one subsurface (2 to 3 feet below mudline [bml]) sediment sample was collected at LRIS-CL-02 to define the vertical extent of dioxin impacts identified at this location in 2010. Chemical testing included testing for conventionals, dioxins, and grain size. Results were summarized and reported to Ecology (MFA, 2012a).

2.4 Geology

Four principal geologic units underlying the Site have been identified. These are fill, younger alluvium, older alluvium, and the Troutdale Formation. The terms "younger alluvium" and "older alluvium" are used to differentiate between unconsolidated geologic materials associated with two distinct depositional events. The designation of the Troutdale Formation is consistent with the nomenclature used by Mundorff (1960). A minor component of the LRIS consists of fill material. No significant lithologic change was observed from north to south across the LRIS. This approximately follows the strike of Lake River, which in turn approximates the strike along the Columbia River floodplain. Figure 2-4 shows the locations of geologic cross sections, and cross sections showing geologic interpretation of the LRIS are included as Figures 2-5 through 2-11. Figures 2-5 to 2-7 show lithologic change from north to south along the strike of Lake River. Figures 2-8 through 2-11 show lithologic change from east to west. The lithology is relatively consistent from north to south; however, from west to east the lithology varies from the uplands toward the Columbia River basin. The younger alluvium (clayey silts, sandy silts, and sands) thickens to the west toward Lake River and the Columbia River. The younger alluvium truncates the older alluvium and upper Troutdale Formation as it thickens east to west. Older alluvium (sandy gravel) is thicker to the east. The silty gravel is the aquitard and is believed to be the weathered surface of the Troutdale Formation. The upper Troutdale Formation gravels are truncated by the younger alluvium sand west of the LRIS. Therefore, the aquitard between the upper water-bearing zone (UWBZ) and the lower water-bearing zone (LWBZ) beneath Cell 1 and the eastern portion of Cell 2 is absent on the western portion of Cell 2.

A clay layer was identified below the sandy gravels of the upper Troutdale Formation in subsurface soils adjacent to the east and west sides of Lake River at the western portion of Cell 2 of the LRIS. The clay layer was very stiff, dry to damp, and is possibly part of the lower Troutdale Formation (Mundorff, 1960). Borings in other areas of the LRIS have not been advanced deeply enough to encounter the lower Troutdale Formation. The clay unit observed west of Lake River in the RNWR was 37 feet thick and was underlain by the Columbia River Basalt Group (CRBG). The clay unit likely prevents chemicals from migrating downward to the CRBG.

2.5 Hydrogeology

Detailed hydrogeologic descriptions are provided in the Cells 1 and 2 RI/FS and the Cell 3 RI/RA (MFA, 2007, 2011a). A recent letter reported on groundwater results through August 2011 (MFA, 2012c). Ecology's comments on the groundwater letter are incorporated in this document.

Figure 2-12 shows the monitoring wells that were present on the Site as of January 2012. Tables 2-1 through 2-6 present completion details for monitoring wells and for extraction and injection wells, summarize water levels, and show potential head differences between the water-bearing zones (WBZs) and between WBZs and surface water bodies.

Hydrogeologic data indicate that two WBZs occur beneath the Site. They have been termed upper and lower WBZs for purposes of discussion (UWBZ and LWBZ, respectively). The UWBZ occurs in the silts and sands of the younger alluvium and the sandy gravels of the older alluvium. The LWBZ occurs in the weakly cemented, sandy gravels of the Troutdale Formation. The UWBZ and LWBZ are separated by compact, iron-stained, silty sandy gravel that forms an aquitard over much of the eastern half of Cell 2 and all of Cells 1 and 3. This aquitard is not present in the western half of Cell 2.

The UWBZ is approximately 35 feet thick (approximately +5 to 15 feet National Geodetic Vertical Datum of 1927/1947 [NGVD] to -20 to -30 feet NGVD)[1] where the aquitard is present and is unconfined, with wells screened at differing depths in either the shallow or deep portion of the UWBZ in Cells 1, 2, and 3 and the RNWR. Shallow UWBZ wells are screened across the water table, and deep UWBZ wells are screened just above the aquitard or where the aquitard is not present at depths similar to those of the wells that are installed on top of the aquitard. Well construction details, including feet below ground surface (bgs), are included in Table 2-1. No monitoring wells were constructed in Cell 4 because reconnaissance groundwater sampling showed that contaminants were not present in Cell 4 above Method B groundwater CULs.

Potentiometric surfaces for the shallow and deep parts of the UWBZ have been evaluated separately because a significant vertical gradient was observed in wells screened in the different portions of the UWBZ, as described further below. Based on water levels in clustered well pairs that are screened in different parts of the UWBZ in Cells 1, 2, and 3 and the RNWR, the estimated groundwater flow direction in the shallow and deep portions of the UWBZ is generally toward Lake River and Carty Lake.

The LWBZ is approximately 50 to 60 feet thick and includes monitoring wells screened between -30 feet and -84 feet NGVD (see Table 2-1 for well construction details). The estimated groundwater flow direction in the LWBZ is toward Lake River.

---

[1] Relationship of NGVD and feet bgs is shown in Table 2-1.

While the elevation of the potentiometric surfaces in the shallow and deep UWBZ and the LWBZ varies throughout the seasons, the flow patterns throughout the Site are seasonally consistent (MFA, 2007, 2011a). Figures 2-13, 2-14, and 2-15 show the potentiometric surface for the shallow and deep UWBZ and the LWBZ, respectively, using August 2011 water levels. A comparison of the shallow UWBZ gradient and hydraulic head differences between Lake River and the shallow UWBZ indicates that the shallow portion of the UWBZ discharges to Lake River.

It is unlikely that groundwater from the deep UWBZ discharges to Lake River because (1) there is a downward vertical gradient from the shallow UWBZ to the deep UWBZ, and (2) there is fine-grained lithology between the base of Lake River (i.e., fine grained, low-permeability sediments) and the deeper portion of the UWBZ. The base of Lake River typically ranges from approximately -5 to -10 feet NGVD, while the deep UWBZ wells along the bank of Lake River range from approximately -20 to -50 feet NGVD. The hydraulic head difference between Lake River and the deeper UWBZ monitoring wells adjacent to Lake River shows an overall slight upward flow potential of groundwater (see Table 2-6); however, the lithology below Lake River is clayey silt to silty clay that is underlain by silty sand, sand, and sandy gravel, suggesting that the deep UWBZ does not discharge to Lake River. The difference in permeability between the clayey silt and the sand or sandy gravel underlying Lake River likely creates a boundary condition where groundwater will not discharge to Lake River. However, to be conservative, groundwater modeling evaluations assume that the deep UWBZ discharges to Lake River.

Groundwater from the LWBZ likely does not discharge to Lake River because (1) there is a generally downward vertical gradient from the deep UWBZ to the LWBZ (see Table 2-5), and (2) there is fine-grained lithology at the base of Lake River (i.e., fine-grained, low-permeability sediments). The average head difference between monitoring wells installed next to Lake River and in the deep UWBZ and LWBZ shows an overall potential downward gradient. The only nested wells that show slight upgradient potential (MW-55D and MW-58D) are next to Lake River, where there is no aquitard. Because of the vertical separation and tendency for a downward head potential, it is unlikely that the LWBZ discharges to Lake River.

The potentiometric surfaces for the shallow and deep UWBZ and the LWBZ show that groundwater flow is always toward Lake River or Carty Lake. Figures 2-13, 2-14, and 2-15 represent typical flow directions in these WBZs. Regular water level monitoring began in 2002, and since that time no flow reversals have been observed. Groundwater monitoring conducted in October 2004 to evaluate tidal effects on water levels indicates that water levels are only slightly influenced by tidal changes (approximately 0.05 foot [shallow UWBZ] and 0.3 foot [deep UWBZ]) in Lake River water levels (Table 2-6).

Twelve monitoring wells have been installed in and adjacent to the southern portion of Carty Lake in the UWBZ. This portion of the lake bottom is exposed when the lake level drops in the summer. During winter and spring months when the lake is recharged by rainfall and by Gee Creek at the north end of the lake, the southern area of the lake, where the monitoring well cluster pairs are located, is inundated. The water levels in the monitoring wells installed in the shallow and deep UWBZ are below the water level of Carty Lake, with an average head difference of 1.2 feet (see Table 2-6). The head difference indicates that the groundwater flow potential is downward. During installation of monitoring wells in and near Carty Lake, a potential confining layer composed of clay, which would restrict movement of water, was identified in the borings ranging from the lake bottom to 2.5 feet bgs. Based on lithology and head potential, the UWBZ will not discharge to Carty Lake (MFA, 2011a). However, to be conservative, groundwater modeling evaluations assume that the shallow and deep areas of the UWBZ discharge to Carty Lake.

As discussed in detail in the Cells 1 and 2 RI/FS (MFA, 2011a) and the Cell 3 RI/RA (MFA, 2007) conservative modeling evaluated compounds present in groundwater near the boundaries of Lake River and Carty Lake. The model assumed that groundwater in the entire UWBZ discharged to the surface water bodies. The modeling showed that concentrations in groundwater would not adversely impact surface waters. Specifically, modeling showed that compounds would naturally attenuate to concentrations below method reporting limits (MRLs) and/or to below ambient water quality levels or natural background concentrations before discharging to Lake River or Carty Lake. Additional information about the modeling, criteria, and results is provided in Section 5.2.3.

2.6 Stormwater System

The historical LRIS stormwater system and paved areas are shown in Figure 2-16, and the stormwater system is described below with respect to each cell. The interim actions on the LRIS have completely decommissioned the historical stormwater system, installed a clean cap, and installed a new stormwater system. Figure 2-17 shows the configuration of the new stormwater system.

2.6.1 Cells 1 and 2

Historically, Cells 1 and 2 drained to three outfalls: OF-2, OF-3, and OF-4. The drainage area of each outfall is described below.

OF-2 drained the west-central area of the LRIS and consisted of a series of trench drains, catch basins, and associated piping. Many of the top grates for the trench drains were constructed of wood planks or steel plates. Some of the trench drains were located inside buildings; however, they functioned as closed pipes, as the surface was solid.

OF-3 drained the north and central portions of the LRIS property and consisted of trench drains, catch basins, and piping. Industrial operations in the OF-3 drainage basin included the SER treatment system and wellfield. In addition to stormwater, OF-3 historically received boiler blowdown process water and treated groundwater from the SER system, permitted under WA0041025. The boiler blowdown entered the OF-3 collection system near CB-6, and the treated groundwater entered OF-3 near CB-11. Past improvements to the OF-3 basin in 1996 included replacement of the concrete pond with a catch basin and piping between the concrete pond area and CB-20. This improvement was removed in 2011 during the installation of the new stormwater system.

OF-4 drained the area north of the SPY and across from Division Street. The office building and Port employee parking were located in the OF-4 drainage basin. The stormwater system that drained to OF-4 consisted of trench drains, catch basins, and piping. Historically, this area was used for storage of treated dimensional wood. As an early interim action focused on addressing high zinc concentrations observed in OF-4 effluent, in June 2009 200 lineal feet of corrugated metal pipe between OF-4 and CB-33 was replaced with high-density polyethylene. The 2011 interim action in Cell 2 removed this improvement.

As part of the interim action completed in Cells 1 and 2 (see Section 4), the historical stormwater system and the changes made during early interim actions were removed and replaced with a new system, including three outfalls, OF-7, OF-8, and OF-9 (see Figure 2-17). The new system uses a series of catch basins to collect overland flow from the newly capped surface and discharges through the three new outfalls. Cell 4 stormwater is directed south to the new Cell 2 stormwater system and eventually discharges through OF-9.

2.6.2 Cell 3

Historically, Cell 3 had one outfall, known as OF-1. This outfall was used by PWT during their operations and discharged stormwater to Lake River from Cell 3.

OF-1 was decommissioned as part of the Cell 3 interim action during the summer of 2010 and was replaced with outfalls OF-5 and OF-6 (see Figure 2-17). Both outfalls receive drainage from Cell 3, which is composed of a vegetated, pervious surface that was capped as part of the interim action in Cell 3 (see Section 4).

2.6.3 Cell 4

Historically, stormwater on Cell 4 primarily infiltrated the surface. In 1996, the Port constructed a berm along the western edge of Cell 4 to direct noninfiltrating stormwater south to Cell 2 and eventually to the OF-3 basin.

During the Cell 4 interim action, two catch basins were installed, temporarily diverting stormwater to OF-3 (see Section 4). The 2012 Cells 1 and 2 interim action removed OF-3 and redirected Cell 4 stormwater to OF-9 in Cell 2 (see Section 4).

2.7 Aquatic Environment

The Lake River fluvial environment and Carty Lake aquatic environment are described in the following sections. Information is compiled from the sediment RI data memorandum (Anchor and MFA, 2011), Port investigations, and available regional information.

2.7.1 Lake River

2.7.1.1 Hydrodynamics

Lake River is hydraulically connected at its mouth to the Columbia River, through Bachelor Island Slough approximately 1 mile upstream of the mouth, and through a tide gate/flushing structure along the western shoreline of Vancouver Lake. The hydrodynamic regime in Lake River is dominated by influence from the Columbia River and, to a lesser degree, by upland drainage through several small creeks that flow into Lake River upstream of the LRIS.

Lake River receives upland drainage from a basin comprising approximately 150 square miles. The basin includes Vancouver Lake, Burnt Bridge Creek (which drains to Vancouver Lake), Salmon Creek, Whipple Creek, Flume Creek, and other, smaller, subbasins. Detailed hydrology for the Lake River system is not available; however, the estimated mean annual flow in Lake River is approximately 300 cubic feet per second (Bhagat and Orsborn, 1971). Water from the Columbia River historically has flowed or has been pumped into Vancouver Lake through a flushing channel during certain times of the year to facilitate flushing of the lake and Lake River. The flushing structure is composed of two 84-inch culverts with tide gate structures built under Lower River Road along the western shoreline of the lake (Gary Struthers Associates, Inc., 2005).

The flow direction in Lake River changes seasonally, depending on the flow (and water surface elevation) in the Columbia River and the flow into Lake River from upstream drainage (USEPA, 1979). For purposes of this discussion, "upstream" refers to the direction toward Vancouver Lake and "downstream" refers to the direction toward the Columbia River (i.e., Lake River mouth). Flow direction data have not been collected; however, the predominant flow direction is assumed to be toward the Columbia River. Observations indicate that surface water levels fluctuate during the summer and are connected with tidal influences. During the winter months, generally November through March, net flow is typically downstream toward the Columbia River because of the high volume of rain runoff from Salmon Creek and Burnt Bridge Creek. During the spring, generally April through June, snowmelt raises water levels in the Columbia River, and net flow in Lake River is toward Vancouver Lake. Flow velocity data are not available for Lake River; however, velocities are assumed to be low because of minimal upstream freshwater input (on average) and backwatering from the Columbia River during periods of high flow and/or high tide.

Data regarding tides on the Columbia River just upstream of the mouth of Lake River at St. Helens, Oregon, are available (NOAA Tide Station No. 9439201). The mean tidal excursion (difference between mean higher high water and mean lower low water, based on gauge data) at St. Helens is 3.3 feet. Water level data at St. Helens were compared to water levels taken during data collection in Lake River at the LRIS. The water levels in Lake River were, on average, 1 foot higher than at the St. Helens gauge during low tides, but were otherwise close in value to those measured at St. Helens. Water level data collected in Lake River during a water quality study of Vancouver Lake (Bhagat and Orsborn, 1971) showed similar trends.

2.7.1.2 Bathymetry

Lake River bathymetric surveys were conducted in 2004 and 2008 as part of the Port's planning activities. The bathymetric surveys included the entire length of Lake River adjacent to the upland portion of the LRIS. In addition, surface sediment elevations were obtained during the Lake River 2010 RI sediment sampling activities at specific locations and were consistent with elevations from the bathymetric surveys (Anchor and MFA, 2011). COE dredging records and existing bathymetry show relatively high deposition rates in Lake River in areas adjacent to the LRIS. Figure 2-18 shows the difference in Lake River mudline elevations from 1970 and the latest updated bathymetry surveys completed in 2010. Based on files provided by the COE, the greatest dredging depth in Lake River adjacent to the LRIS appears to be from 1970. The 1970 survey is a post-dredge survey, and no maintenance dredging has taken place since then, based on available information. The sediment thickness contours shown on Figure 2-18 are approximate because of survey measurement resolution in 1970 and the lateral extent of available data from the 1970 condition survey. Based on these evaluations, deposition rates in Lake River vary by location and can be up to 0.3 foot per year in the channel areas.

2.7.1.3 Sediment Characteristics

Grain size and total organic carbon (TOC) data were collected from 28 surface locations and nine subsurface locations during Lake River 2010 RI sediment sampling activities (Anchor and MFA, 2011). Tables 2-7 and 2-8 summarize surface and subsurface TOC and grain size data. In surface samples, TOC ranged from 0.34 to 3.2 percent. TOC concentrations in subsurface samples ranged from 0.13 to 3 percent.

Lake River surface sediment is characterized as a fine sand and silt, the relative quantities of which vary in different areas of Lake River. Subsurface sediment in Lake River varies, based on the sampling location. Generally, on the nearshore slope areas, the sediment is characterized as a fine, sandy silt to a depth of approximately 5 feet bml that then transitions to a fine to medium sand. Subsurface sediment in the channel areas of Lake River is generally a very fine, sandy silt from the length of the core up to 11 feet bml. Fine to medium sand was encountered in two cores (LRIS-LR-02 and LRIS-LR-13) in the Lake River channel area at approximately 6 to 7 feet bml. Surface grain size results are summarized in Table 2-7 and are shown on Figure 2-19. Boring logs are available in the sediment RI/FS (Anchor and MFA, 2011).

2.7.1.4 Fluvial Dynamics Summary

Low-flow velocity, bathymetric and historical analysis (see above), and grain size distribution all indicate that Lake River features a predominantly depositional fluvial environment. Typically, fine-grained sediments (silts, clays) dominate in relatively low-energy environments where current velocities are low enough to allow fine particles to settle out of the water column and remain deposited, whereas coarse sediments (sands, gravels) are indicative of higher-energy environments where fines are kept in suspension in the water column and/or winnowed out of previously deposited material and transported away during high-energy events (e.g., floods or anthropogenic disturbances, such as propeller wash and dredging). Figure 2-19 shows that percent fines in most Lake River areas are generally high (> 40 percent) and can exceed 70 percent, indicating areas of deposition. Percent fines are relatively low (< 20 percent) in several areas directly adjacent to outfalls that discharge near the water/sediment interface, likely causing some erosion. For comparison, fines in the mid-channel Willamette River in the Portland Harbor Superfund Site are generally less than 20 percent, excluding areas known to be highly depositional (Integral et al., 2009). While local scouring may occur during large flood events, outfall discharge, and because of propeller wash, the fluvial characteristics suggest that deposition occurs over most of Lake River's length. This is further supported by the complete filling of the historical turning basin that had been dredged for barges offshore of Cell 3 (see Figure 2-1).

2.7.2 Carty Lake

2.7.2.1 Hydrodynamics

Carty Lake is a 52-acre, ponded wetland located in the RNWR Carty Unit. During the rainy season, Gee Creek and Carty Lake can be hydraulically connected at the lake's northern end. During most of the year, Carty Lake has no outlet. Water levels range from 3 to 10 feet, varying seasonally, and are generally higher during winter and spring and lower during summer and fall. Water fluctuations are generally muted relative to Lake River, with increases and decreases occurring more gradually because there is no direct connection with the Columbia River.

During installation of monitoring wells in and near Carty Lake, a potential confining layer composed of clay, which would restrict movement of water, was identified in the borings. Clay was present upland near Carty Lake between approximately 5.6 and 9.0 feet bgs, and was most prominent in Carty Lake sediments from the surface to approximately 2.5 feet bgs. Based on lithology and head potential, the UWBZ does not discharge to Carty Lake, and it is unlikely that Carty Lake significantly discharges to the UWBZ in the lake's southern portion (MFA, 2011a).

2.7.2.2 Sediment Characteristics

Grain size and TOC data were collected from all surface and some subsurface sediment samples during 2010 (Anchor and MFA, 2011) and 2011 sediment sampling activities (MFA, 2012a). Carty Lake sediment characteristics are summarized in Table 2-9. In surface samples, TOC ranged from 1.3 to 5.4 percent. TOC generally decreased with depth (e.g., LRIS-CL-02 at 2.8 percent [1 to 2 feet bml] and 0.84 percent [2 to 3 feet bml]).

Percent total fines (silt and clay) generally dominated the particle size distribution, ranging from 56 to 93 percent in surface samples, with an average and median of 75.9 percent and 75.9 percent, respectively (see Figure 2-20).

2.7.2.3 Fluvial Dynamics Summary

Carty Lake is a low-dynamic environment. Hydrodynamics and grain size distribution indicate that Carty Lake features a low-energy, depositional environment. As indicated above, percent fines in Carty Lake are high, generally over 75 percent fines. Carty Lake's hydraulic exchange with other surface water bodies is limited to unusually high water events. Further, given that human access to Carty Lake is limited and boat access is restricted, anthropogenic high-velocity events are not expected.

2.8 Current and Future Land Use

Figure 2-21 depicts current zoning designations for the Site. Current and future land uses are summarized in this section.

2.8.1 Lake River Industrial Site

The LRIS is currently zoned for waterfront mixed use. Small portions of the LRIS were used for industrial purposes while the Port conducted RIs and interim actions. The LRIS is currently vacant and the Port is planning to redevelop it. Future land use may include a combination of commercial, light industrial, and retail developments. Ground floor residential and heavy industrial uses are not part of future land use plans and are prohibited by the zoning code. The Port plans to retain ownership of the LRIS. To support these types of land use, portions of the LRIS require placement of up to 5 feet of fill before development to bring their elevation above the 100-year floodplain.

2.8.2 Upland Off-Property

The upland off-property area is located north, east, and south of the LRIS (see Figure 2-2). The upland off-property area includes Port-owned properties and non-Port-owned properties. Current and future land uses for the following areas include:

- Port Railroad Avenue properties (east of LRIS): The Port owns two parcels along Railroad Avenue just east of the LRIS. These properties are undeveloped at this time and are zoned waterfront mixed use. The Port anticipates developing commercial parking lots on these parcels in the future; the area would require fill and commercial-grade asphalt layering for a single-level, at-grade parking lot.
- Port marina property (south of LRIS): The property immediately south of the LRIS includes the parking and landscaped areas for the Port-owned boat launch. This area is currently zoned waterfront mixed use. The Port plans to retain ownership and continue to use the area as parking for the foreseeable future.
- Port proposed overpass property (south of LRIS): The overpass area was formerly part of McCuddy's Marina and includes the footprint of a proposed overpass development. This area will be covered with a cap consistent with LRIS capping options.
- McCuddy's Marina (south of LRIS): The privately owned marina contains parking and open space for residential boathouses. This area is currently zoned waterfront mixed use. It is likely that the marina site use will remain unchanged for the foreseeable future.
- RNWR property (north of LRIS): This area is currently and likely will remain zoned parks/open space.
- Other off-property areas (east of LRIS): The remaining off-property area east of the LRIS is currently zoned low-density residential (the area is zoned primarily for 5,000-square-foot or larger lots, but an area zoned for 7,500-square-foot or larger lots is designated in the northern reach); a small area in the northwest is zoned urban public. Primary land use is expected to remain residential.

Except for the RNWR property, there is substantial development in the upland off-property area and there is minimal viable ecological habitat.

2.8.3 Lake River

Lake River is an area of high human traffic and boat use; a boathouse community, in-water and overwater structures (including the Port's pump house), and a public access float dock are all located along Lake River's eastern shoreline. The location and status of Lake River channel maintenance are described in Section 2.2.3. Future land use at the adjacent LRIS Cells 1, 2, and 3 may include a combination of commercial, light industrial, and retail developments.

Fishing activity in Lake River likely is low, as fishing is generally more popular in the cooler waters of the Columbia River. Under the RNWR 2010 Comprehensive Conservation Plan, the RNWR will evaluate fishing access enhancement opportunities in the River "S" Unit. This may result in an increase of fishing visits at Lake River, although currently only approximately 260 lake and bank fishing visits (the RNWR has no developed facilities specifically for fishing) take place annually throughout the entirety of the RNWR that is open to the public (i.e., the Carty Unit) (USFWS, 2010).

2.8.3.1 Natural Resources

Because of its proximity to the Columbia River, Lake River can be used by anadromous fish, and nearby areas may provide habitat for a diversity of species, including fish, plants, birds, and mammals. A Lake River habitat evaluation and special-status species information are provided in Appendix C. Lake River ecology is summarized below:

- Special-status fish species potentially present in Lake River include: steelhead (rainbow trout), Chinook salmon, coho salmon, chum salmon, sockeye salmon, coastal cutthroat trout, and Pacific smelt (Eulachon). Federally designated Pacific salmon and Eulachon critical habitat is identified for Lake River.
- Washington State priority-designated palustrine aquatic habitats are present along stretches of Lake River. In addition, three special-status plant species have been identified as historically or potentially present in the Carty Unit along which Lake River runs: water howellia, Bradshaw's desert parsley, and Nelson's checker-mallow. Where Lake River passes high-human-impact areas, vegetation such as reed canary grass, yellow marshcress, California false indigo, Himalaya blackberry, Pacific willow, Douglas fir, black cottonwood, and nonnative invasive shrub species is common.
- Common waterbird species that use wetlands along Lake River include coot, pied-billed grebe, double-crested cormorant, great blue heron, and the great egret. The riparian and floodplain forests adjacent to Lake River host breeding terrestrial species, including commonly seen resident and migrant species such as downy woodpecker, northern flicker, and western wood-pewee. Washington Department of Fish and Wildlife (WDFW) priority-designated purple martin foraging areas occur near Lake River. At least six pairs of bald eagles are known to nest and breed within approximately 1 mile of Lake River.
- American beaver, mink, muskrat, river otter, common opossum, and nutria inhabit wetlands along Lake River. Other mammals, including mule deer, coyote, raccoon, and

striped skunk, occur along the Lake River shoreline. Special status-listed Columbian white-tailed deer have recently been translocated to the RNWR and may occur near Lake River.

2.8.4 Carty Lake

Carty Lake has limited recreational uses (USFWS, 2010), but can include wildlife photography, wildlife observation, environmental education, and fishing. Boating is not allowed. Trails lead to the Gee Creek portion of the Carty Unit for fishing. Carty Lake itself is not currently readily accessible to visitors; the RNWR maintains a mowed seasonal footpath along the north end of the lake, but this path is flooded during high-water periods and is not heavily used. However, the potential exists for the RNWR to work with the Port to develop a loop trail adjacent to Carty Lake for the public to access from the Port property. At the RNWR, fishing is allowed in areas open to the public on the Carty Unit; the Carty Unit receives approximately 260 fishing visits per year, with use distributed among Gee Creek, Duck Lake, Middle Lake, and Carty Lake (USFWS, 2010), suggesting that public-use activities near or in Carty Lake are currently uncommon.

In the future, USFWS may consider the feasibility of reconnecting Carty Lake either to the Columbia River via Gee Creek or to Lake River through a constructed channel. Of the two options, the Gee Creek connection likely would be most feasible in terms of construction and access for salmonids such as cutthroat trout and coho salmon. The resulting hydrology of the lake could vary considerably, depending on the option selected; however, some changes to the fish, wildlife, and vegetation communities would be expected (USFWS, 2010), and implementation would need to consider the potential for contaminant impacts to fish and the potential for contaminant migration.

Potential Carty Lake restoration efforts could promote more robust emergents such as tule, wapato, and cattail, and submergents such as Eurasian milfoil and reed canary grass would probably still be prevalent in the seasonally flooded portions of the wetlands; however, mechanical treatments such as disking and mowing would allow the RNWR to improve the coverage of native vegetation. Additional efforts to establish riparian forest and shrub vegetation along Gee Creek and the east side of Carty Lake may be considered. Carty Lake historically contained a large native wapato bed, which is currently confined to small areas of Carty Lake. The Cowlitz Tribe historically incorporated wapato into their diets (USFWS, 2010), and may desire to use Carty Lake for wapato harvest again in the future (Mercuri, 2012).

2.8.4.1 Natural Resources

Diking and filling, in conjunction with agricultural development, have been a primary cause of decreases in tidal wetland area in the Columbia River estuary. These actions have eliminated most of the natural tidal exchange of water, materials, and organisms between the Columbia River and the adjacent floodplain forests and overflow lakes. Because Carty Lake lacks a consistent connection with the Columbia River system, the lake's functionality has been reduced, particularly with respect to anadromous fish rearing habitat and native mussel beds.

Carty Lake and its adjacent areas may provide habitat for a diversity of species, including fish, plants, birds, and mammals. A Carty Lake habitat evaluation and special status species information are provided in Appendix C. Carty Lake ecology is summarized below:

- As with other permanent nontidal wetlands on the RNWR, water quality and aquatic plants have been negatively impacted by introduced carp. Fish found in the RNWR where Carty Lake lies include primarily warm water fish, e.g., introduced carp and largescale sucker. Because Carty Lake does not maintain connectivity with the Columbia River, state and federally listed anadromous species such as Chinook and coho salmon are currently unlikely to utilize Carty Lake for spawning or rearing habitat. Federally designated Pacific salmon critical habitat is identified for Gee Creek to the northeast of Carty Lake.
- The lake contains WDFW priority-designated palustrine habitat, and Oregon white oak woodland priority habitat occurs directly adjacent to the east and north of Carty Lake. Three special-status plant species have been identified as historically or potentially present in the Carty Unit: water howellia, Bradshaw's desert parsley, and Nelson's checker-mallow. In addition, Oregon white oak woodlands are a WDFW priority-designated habitat. Oregon white oak woodlands occur adjacent to the east and north of Carty Lake. Wapato beds, confined to small areas of Carty Lake, are composed of emergent aquatic plants (tubers) in the family *Alismataceae* and are good indicators of suitable red-legged frog breeding habitat (USFWS, 2010).
- Common piscivorous species that use RNWR wetlands such as Carty Lake include double-crested cormorant, great blue heron, and great egret. Tundra and trumpeter swans are common in the winter, as are dabbling ducks such as American widgeon, northern pintail, and mallard. Other waterbirds such as coot and pied-billed grebe are also abundant. Special-status sandhill crane may aggregate at Carty Lake. The riparian and floodplain forests adjacent to Carty Lake host breeding terrestrial species, including commonly seen resident and migrant species such as downy woodpecker, northern flicker, and western wood-pewee. Bald eagles have been sighted using riparian trees on or near the RNWR for roosts from December through March, and three pairs are known to nest and breed approximately 1 mile northeast of Carty Lake.
- American beaver, mink, muskrat, river otter, common opossum, and nutria inhabit wetlands in the RNWR such as Carty Lake. Other mammals, including mule deer, coyote, raccoon, and striped skunk, may occur along the Carty Lake shoreline. Special status-listed white-tailed deer may occur on or near Carty Lake.

3 NATURE AND EXTENT

This section delineates areas of contamination based on available information from previous and current investigations. Chemicals detected in one or more samples are screened against relevant criteria to determine IHSs. IHSs are those compounds that are included for further consideration during the development of the cleanup approach because of their frequency, mobility, persistence in the environment, or toxicity. Compounds can be eliminated from further consideration on a site-specific basis, using the following evaluation factors outlined in WAC 173-340-703:

- The toxicological characteristics of the hazardous substance relative to the concentration of the hazardous substance at the Site
- The chemical and physical characteristics of the hazardous substance that govern its tendency to persist in the environment
- The chemical and physical characteristics of the hazardous substance that govern its tendency to move into and through environmental media
- The natural background concentrations of the hazardous substance
- The thoroughness of testing for the hazardous substance at the Site
- The frequency at which the hazardous substance has been detected at the Site
- Degradation by-products of the hazardous substance

The nature and extent of chemicals detected in soil (on the LRIS and off-property), in groundwater, and in sediment (in Carty Lake and in Lake River) are described below.

3.1 Data Usability

Analytical results collected during Port RI activities are reviewed for usability and are qualified consistent with USEPA procedures and appropriate laboratory and method-specific guidelines. Data quality review memoranda for historical data that have been previously submitted to Ecology are available in the reports referenced in Section 2. Laboratory analytical reports and data review memoranda for data not previously submitted to Ecology (i.e., SER soil and groundwater results discussed in Section 4) are provided in Appendix D. Historically collected soil data are presented in Appendix E. All validated analytical data have been uploaded to Ecology's Environmental Information System database.

Consistent with WAC 173-340-708(8), mixtures of dioxins and carcinogenic PAHs (cPAHs) are considered as single hazardous substances when evaluating compliance with CULs and remediation levels (RELs) such that the toxicity of a particular congener is expressed relative to the most toxic dioxin congener (i.e., 2,3,7,8-tetrachloro dibenzo-p-dioxin [TCDD] and benzo(a)pyrene, respectively). The toxicity of dioxins and cPAHs as groups was assessed using a toxic equivalency approach. Each congener in the group is assigned a toxic equivalency factor (TEF) describing the toxicity of that congener relative to the toxicity of the reference compound, TCDD or benzo(a)pyrene. For example, a congener that is equal in toxicity to TCDD would have a TEF of 1.0. Similarly, a congener that is half as toxic as TCDD would have a TEF of 0.5, and so on. Multiplying the concentration of a congener by its TEF produces the concentration of TCDD or cPAH that is equivalent in toxicity to the congener concentration of concern, known as the toxicity equivalent concentration (TEC). Computing the TEC for each congener (Ci in the equation below) in a sample, followed by summing all TEC values, permits expression of all congener concentrations in terms of a total TCDD or cPAH toxicity equivalent (TEQ) (i.e., dioxin TEQ and cPAH TEQ, respectively):

$$\text{Dioxin TEQ} = \sum_{i=1}^{k} \text{Ci x TEFi}$$

$$\text{cPAH TEQ} = \sum_{i=1}^{k} \text{Ci x TEFi}$$

Dioxin and cPAH TEQs were qualified and calculated as follows:

- Congeners qualified as non-detect and flagged with a "U" are used in the TEQ calculation at one-half the associated value.
- Congeners qualified as estimated and flagged with a "J" are used without modification in the TEQ calculation.
- Congeners qualified as non-detect with an estimated limit (i.e., flagged with a "UJ") are used in the TEQ calculation at one-half the associated value.
- If all congeners in a chemical group are undetected, the group sum is reported as undetected.

For further details on data validation and the TEQ calculation methodology used for dioxin screening, see Appendix F. The most recent effort to develop TCDD TEFs for dioxins was made at an expert meeting organized by the World Health Organization in 2005 (Van den Berg et al., 2006) and used multiple lines of evidence to develop a consensus-based list of TEFs for mammal, bird, and fish receptors. TEFs for cPAHs were used consistent with WAC 173-340-708(8).

3.2 Soil

Drawing 1 shows all soil sample locations for the Site, including reconnaissance borings, surface soil samples, test pits, monitoring wells, and confirmation samples from excavations. Tables showing the data from soil collected on the LRIS are included in the Cell 3 RI/RA (MFA, 2007), Cell 4 RI/FS (MFA, 2010e), and Cells 1 and 2 RI/FS (MFA, 2011a) and are included in this report as Appendix E. Detailed results for specific areas of the Site are discussed below. Interim actions have been conducted or are currently under way to address the impacts described below. Section 4 describes the interim actions.

3.2.1 LRIS

Previous LRIS investigations have provided data regarding surface and subsurface on-site soil from 1993 to the present. Results were previously reported to Ecology (see Section 2.3). To evaluate the nature, extent, and potential risks associated with exposure to soil, chemical contamination was compared to MTCA Method B CULs for unrestricted land use. Because MTCA Method B CULs do not take into account naturally occurring background levels of metals or regional ambient levels of organic chemicals, some MTCA Method B CULs are above natural or anthropogenic background levels. Therefore, chemical concentrations in soil were also compared with background levels. No value for MTCA Method B CULs is provided for petroleum hydrocarbons. Petroleum hydrocarbon values are compared to MTCA Method A CULs. Chemical concentrations in soil were also screened against the wildlife ecological indicator concentrations (EICs) provided in MTCA Table 749-3 as part of the LRIS TEE (MFA, 2010a).

Although applicable only to industrial sites, MTCA Method C CULs for industrial use were compared to soil concentrations on the LRIS. This comparison was conducted to determine areas where wood-treating chemicals were present at significant concentrations. "Hot spots" were identified by comparing soil concentrations to MTCA Method C CULs and generally were excavated later, during interim actions (see Section 4).

An on-property TEE (MFA, 2010a) was conducted for the entire LRIS to gather sufficient information to evaluate the ecological protectiveness of remedial alternatives. The TEE included problem formulation and an ecological screening evaluation, as well as an evaluation of the nature and extent of IHSs on the LRIS, as summarized below. The on-property TEE is provided in Appendix B.

Data used to evaluate the nature, extent, and potential risk associated with chemical concentrations in soil were previously submitted to Ecology and are summarized in tables provided in Appendix E. Figures depicting the nature and extent of impacts were evaluated by creating either distribution profiles per depth or three-dimensional (3-D) renderings, using Environmental Visualization System™ software (EVS), which uses kriging (i.e., a geostatistical method of estimating concentrations based on spatially limited data) to estimate concentrations beyond the locations at which the samples were collected. The soil figures used to graphically depict soil impacts throughout the LRIS are included as Appendix G. All soil data were used to create the figures in Appendix G. The figures show MTCA Method B CUL exceedances, except for the arsenic in the Cell 3 figures, which historically has been compared to MTCA Method A soil CULs based on direct contact and adjusted for natural background concentrations for Washington State. Appendix G has three sections:

- G-1 includes Figures 6-1 through 6-9 from the Cells 1 and 2 RI/FS (MFA, 2011a). Figure 6-1 depicts soil investigation locations and samples by depth used to prepare the 3-D models; this figure includes all soil data. Figures 6-2 through 6-9 in Appendix G-1 show the most widespread and/or toxic of the IHSs in Cells 1 and 2 (i.e., arsenic, cPAH TEQ, PCP, and dioxin TEQ). Two figures were produced for each of the IHSs, one showing impacts within the top 6 feet of soil and the second depicting impacts from 6 feet to 15.0 feet bgs. Figures 6-8 and 6-9 in Appendix G-1 show distribution of dioxin TEQs, but were not modeled because the number of samples and the data density were too low to create an output with requisite certainty.
- G-2 includes Figures 4-1 through 4-12 from the Cell 3 RI/RA (MFA, 2007) and Figure 1 from a letter evaluating dioxin concentrations (MFA, 2010b). Figures 4-1 through 4-9 in Appendix G-2 show the limit of the most widespread and/or toxic of the IHSs in Cell 3 tested for as of 2007 (i.e., arsenic, chrysene, and PCP) for three different soil depths (i.e., 0 to 3.0 feet, 4.0 to 9.0 feet, and 10.0 to 15.0 feet bgs). When the Cell 3 RI was completed, the rules regarding the mixtures of cPAHs (WAC 173-340-708(8)(e)) had not been published. Therefore, cPAHs were evaluated as individual substances, not as a

single hazardous substance. Chrysene was used because it was the most prevalent of the cPAHs. As part of the Cell 3 FS (MFA, 2011c), MFA used the TEFs to evaluate cPAH TEQs and found that the cPAH TEQ distribution is fairly similar to the distribution of cPAHs expressed with chrysene (i.e., it is only slightly reduced).

Dioxins were evaluated after the Cell 3 RI/RA was completed and approved by Ecology. Dioxins were evaluated as part of the Cell 3 FS. Figure 1 in Appendix G-2 shows the dioxin TEQ concentrations throughout the LRIS.

- G-3 includes Figures 5-1 through 5-5 from the Cell 4 RI/FS (MFA, 2010e). Figures 5-1 through 5-4 in Appendix G-3 show the distribution of the most widespread and/or toxic of the IHSs in Cell 4 (i.e., arsenic, cPAH TEQ, PCP, and dioxin TEQ). Figure 5-5 in Appendix G-3 shows the distribution of IHS exceedances throughout Cell 4.

3.2.1.1 IHSs

The following chemicals exceeded the MTCA Method B CULs for soil, based on dermal contact and ingestion, or other applicable CULs such as MTCA Method A CULs for arsenic and petroleum hydrocarbons, and are considered IHSs. The screenings conducted to select IHSs are detailed in the RI/RA or RI/FS reports for each Cell (MFA, 2007, 2010e, 2011a).

- **Metals:** arsenic and total chromium
- **PAHs:** 2-methylnaphthalene, acenaphthene, fluoranthene, fluorene, naphthalene, pyrene, cPAHs, benzo(a)pyrene
- **SVOCs:** dibenzofuran
- **Volatile organic compounds (VOCs):** 1,1,2,2-tetrachloroethane, 1,2,4-trimethylbenzene, styrene
- **Chlorinated phenolics:** PCP
- **Petroleum hydrocarbons:** diesel-range organics (DROs) (diesel), residual-range organics (RROs) (lube oil), gasoline-range organics (gasoline)
- **Dioxins**

Based on the leaching to groundwater pathway, IHSs were not selected in Cells 3 and 4, but were selected for Cells 1 and 2. An evaluation presented in the Cell 3 RI/RA (MFA, 2007) indicated that Ecology's three-phase partitioning model-derived soil CULs generated using the online "Cleanup Levels and Risk Calculation" worksheet did not accurately predict leaching to groundwater in Cell 3. The model predicted significantly higher groundwater concentrations than those actually measured in groundwater. Therefore, empirical groundwater data are used to evaluate compliance with groundwater CULs protective of drinking water in Cell 3. There were no groundwater exceedances in Cell 4; therefore, the leaching to groundwater pathway was not evaluated. However, because empirical data in Cells 1 and 2 showed that leaching to groundwater was occurring, the leaching to groundwater pathway was further evaluated for these cells. The following chemicals exceeded the calculated MTCA Method B CULs for soil in Cells 1 and 2, based on the leaching to groundwater pathway (MFA, 2011a):

- **Metals:** arsenic, cadmium, total chromium, and copper
- **PAHs:** acenaphthene, anthracene, fluoranthene, fluorene, naphthalene, pyrene, cPAHs
- **SVOCs:** carbazole
- **Chlorinated phenolics:** PCP
- **VOCs:** 1,1,2,2-tetrachloroethane, benzene, toluene, ethylbenzene, m,p-xylenes, isopropylbenzene, methylene chloride, styrene, tetrachloroethene (PCE)
- **Dioxins**

However, only a subset of these chemicals was actually detected above Method B CULs in groundwater in Cells 1 and 2. The historical operations that impacted soil ceased years ago, nonaqueous-phase liquid (NAPL) has been removed from the Site through the SER system and concrete pond removal, and there are no current operations generating contaminants. Therefore, it is likely that leaching of chemicals from soil to groundwater has already occurred. The lack of detections in groundwater for some of the chemicals listed above indicates that these chemicals are unlikely to cause unacceptable risk via the leaching to groundwater pathway. Therefore, the IHSs for the leaching to groundwater pathway are limited to those chemicals detected in groundwater and are summarized as follows:

- **PAHs:** acenaphthene, fluoranthene, fluorene, naphthalene, pyrene, cPAHs
- **SVOCs:** carbazole
- **Chlorinated phenolics:** PCP
- **VOCs:** 1,1,2,2-tetrachloroethane; 1,2,4-trimethylbenzene; benzene, styrene

Locations where IHSs were detected in soil above Method B CULs (or Method A CULs for petroleum hydrocarbons), background levels, and/or ecological screening levels are present throughout the LRIS. The details of the exceedances throughout the LRIS are summarized in the RI/RA or RI/FS reports for the different cells (MFA, 2007, 2010e, 2011a). A general description of the nature and extent of impacts on the LRIS is provided below. Figures in Appendix G show the spatial distribution of the most widespread and/or toxic chemicals in surface and subsurface soil, including, but not limited to, arsenic, PCP, cPAHs, and dioxins.

The distribution of IHSs in soil above CULs indicates that the greatest impacts (with the possible exception of dioxins) were in the general vicinity of the SER area (i.e., Cell 1 and portions of Cell 2) and the area around the former concrete pond (see Figures 6-2 through 6-9, Appendix G-1). The focus in the SER area of the treatment system was to remove mobile contaminants and NAPL. NAPL was released at the surface through spills that migrated through the vadose zone to the water table. The soil in the SER area from the surface to the WBZ, being mostly sandy gravel, did not restrict the migration of NAPL. The operation and performance of the SER system and the extent of NAPL pre- and post-SER operation are summarized in Section 4.2. However, considering that most of the data were collected over a decade ago and in view of the recent history of active treatment, some of the chemicals (especially the more mobile compounds) identified as soil IHSs are below their respective MTCA Method C soil CULs. Less mobile IHSs such as arsenic and dioxins were still present in soil above MTCA Method C CULs after SER treatment (see Section 3.2.1.2).

NAPL has also been observed in the former concrete pond area. The soils near the former concrete pond are clays and silts, which limit the migration of NAPL. The fine-grained soil prevented the SER system from operating effectively in this area, and SER has therefore not been applied. There were many NAPL-containing soil samples in this area that were not submitted for analysis because it was assumed that they exceeded CULs. The extent of the NAPL in the concrete pond area is shown on Figure 3-1. As part of the Cells 1 and 2 interim actions in 2011, soil containing NAPL from the concrete pond area was removed to a depth of 15 feet bgs (see Section 4.4.2.1).

In Cell 2 outside the former concrete pond area, impacts above Method B soil CULs were highest in soil near the surface; however, soil below 6.0 feet also showed impacts directly downgradient of Cell 1 and was included in the SER treatment.

IHSs in the remaining areas of the LRIS generally appear to be limited to shallow soils (within the top 6 feet bgs). IHS impacts in Cell 4 generally were limited to the top 2.5 feet of soil and likely were the result of vehicles tracking chemicals from other parts of the LRIS. Impacts above Method B CULs extended below 2.5 feet bgs only in three locations and did not extend below 10.0 feet bgs in Cell 4.

The spatial distribution of Cell 3 impacts indicates that the source likely was related mainly to treated-wood storage and drippage throughout the area. Impacts were greatest at the surface and generally decreased with depth (see Figures 4-10 through 4-12, Appendix G-2). Impacts in Cell 3 tended to extend deeper than Cell 4, with much of the soil down to 6.0 feet bgs exceeding one or more IHSs.

As indicated above, a TEE of the LRIS was performed (see Appendix B). The chemicals that exceeded wildlife ecological screening levels were the same chemicals selected as IHSs, with the exception of barium and zinc. However, in general, the IHSs that exceeded wildlife ecological screening levels were colocated with other IHS CUL exceedances.

3.2.1.2 SER Soil Evaluation

The SER was an emergency interim action designed to remove mobile contaminants (e.g., VOCs and some SVOCs). The SER system was not anticipated to be effective in removing less mobile compounds, such as metals and dioxins. The SER emergency action is further described in Section 4.

In November 2011, MFA conducted a soil investigation to evaluate areas in the SER area where chemical concentrations had exceeded Method C CULs. The purpose of the soil and groundwater sampling in the SER area was to evaluate subsurface conditions after operation of the SER system (see Figure 3-2).

The sampling was conducted consistent with the Ecology-approved sampling work plan (MFA, 2011f), with a few exceptions described below.

Five borings (B-316 through B-320) were completed to assess the soil that had been placed in Cell 1 during previous interim actions and drilling activities. Composite samples were collected from soils placed in Cell 1 and analyzed for PCP, cPAHs, arsenic, DROs, and RROs. Soil that was placed in Cell 1 was generally beneath approximately 0.5 to 1.0 foot of gravel, and the contact with the original tank farm surface was easily defined by a geofabric that had been placed prior to filling. The thickness of soil placed in Cell 1 in the five borings was found to average about 3 to 4 feet. The boring logs are included as Appendix H. The work plan provided for collecting two composite samples per borehole; however, during the fieldwork the thickness of the imported soil was less than anticipated. After consultation with Ecology, it was agreed that a single composite sample would be appropriate if the identified soil sampling interval was less than 4 feet.

Six borings (B-321 through B-326) were advanced to assess past discrete soil locations exceeding MTCA Method C CULs (see Figure 3-2). Figure 3-2 also shows the historical sample locations. Samples were collected for arsenic, PCP, SVOCs, total petroleum hydrocarbons (TPH), and/or dioxins. Discrete soil samples were collected from elevations consistent with past detections. One of the historical locations was beneath some of the SER equipment, and a boring could not advance at this location. Therefore, after consultation with Ecology, one boring (B-325) was installed to assess conditions at both TP-10 and B-85.

Under standard chain-of-custody procedures, soil samples were submitted to Pace Analytical Services of Minneapolis, Minnesota, for analysis of dioxins, and to Specialty Analytical of Clackamas, Oregon, for remaining analyses. Tables 3-1 through 3-4 summarize the soil analytical results from the November 2011 investigation and the historical sample results for the discrete sample locations.

The data were compared to the MTCA Method B and C CULs, except for arsenic and petroleum hydrocarbons, which were compared to natural background concentrations and Method A CULs, respectively.

3.2.1.3 Discrete Soil Analytical Results

The 2011 arsenic concentrations ranged from 4.02 to 241 milligrams per kilogram (mg/kg), and all but one sample from B-321 were higher than the natural background concentration of 5.81 mg/kg (see Table 3-1). The PAH and PCP concentrations were all below MTCA Method B CULs for sample locations, except for B-323 (PCP at 8,380 micrograms per kilogram [μg/kg]) and B-321 and B-322 (cPAH TEQ at 225 μg/kg and 15,626 μg/kg, respectively) (see Table 3-3).

Concentrations of IHSs in soil decreased between historical sample collection (between 1991 and 2009) and the 2011 sampling event, except for the sample collected from B-322, which was evaluated relative to historical sample B-306, collected in 2009.

The arsenic and dioxin TEQ concentrations (241 mg/kg and 8,100 nanograms per kilogram [ng/kg], respectively) exceeded the MTCA Method C CULs of 88 mg/kg for arsenic and 1,500 ng/kg for dioxin TEQ in sample B-322 at 2.5 feet bgs.

3.2.1.4 Composite Soil Analytical Results

Tables 3-1 through 3-4 show the composite analytical results. Arsenic concentrations were above natural background concentrations, but only the sample from B-317 at 1.25 feet bgs exceeded the Method C CUL, with a concentration of 140 mg/kg. cPAH TEQs in B-317 (874.9 μg/kg) and B-318 (270.74 μg/kg) exceeded Method B CULs of 140 μg/kg. PCP concentrations in B-318 (13,700 μg/kg) and B-320 (52,300 μg/kg) also exceeded Method B CULs. Other IHSs analyzed were below their respective MTCA Method B CULs or Method A for TPH.

The arsenic concentration in sample B-317 at 140 mg/kg was the only IHS to exceed the MTCA Method C CULs.

3.2.2 Off-Property

Several off-property investigations have been conducted to characterize surface soil in the following areas: Port-owned properties and public rights-of-way in the neighborhood to the east of the LRIS, Port-owned properties and McCuddy's Marina to the south of the LRIS, and RNWR property north of the LRIS Cell 4 (see Figure 3-3). Off-property sampling was conducted in July 2008; in February 2009; in June, August, and September 2010; and in May 2011 at the request of Ecology (MFA, 2010b,d; 2011e). Additional composite soil (0 to 6 feet bgs) sampling for dioxins was conducted at eight historical surface soil locations in September 2012 (see Appendix B). Off-property sampling efforts focused on the contaminants known to have impacted LRIS soils (i.e., PCP and associated chlorinated phenolics, PAHs, metals [arsenic, chromium, copper, and zinc], and dioxins).

3.2.2.1 IHSs

Contaminants at the off-property area are identified as soil IHSs, based on comparison to MTCA Method B soil CULs protective of human health and environment for residential properties (WAC 173-340-705). Examination of CULs protective of ecological receptors, in a TEE using risk-based criteria, is summarized briefly below and presented in detail in Appendix B. In the off-property areas, no PCP or associated chlorinated phenolics have been detected above Method B CULs. Similarly, PAHs were rarely detected and no exceedances of Method B CULs occurred. Thus PCP and PAHs are not selected as IHSs for off-property soil. See Table 3-5 for a summary of screening results.

Chromium, copper, and zinc were all below Method B CULs in off-property soils and are therefore not considered IHSs. Arsenic concentrations exceeded the Method B CUL of 0.67 mg/kg; however, arsenic is commonly found at levels that exceed risk-based CULs as a result of natural background conditions. Arsenic ranged from 2.78 mg/kg to 9.81 mg/kg on off-property soils and was below the MTCA Method A level adjusted for natural background of 20 mg/kg. Arsenic is not selected as an IHS, given that there are no exceedances of the background-adjusted MTCA Method A level. For a summary of metals results, see Table 3-5.

Dioxins were detected above Method B CULs in portions of off-property areas. Under MTCA, the default soil CUL based on direct contact is 11 ng/kg (Method B soil CUL) for residential properties.

Dioxin concentrations ranged from 0.49 ng/kg to 110 ng/kg in off-property areas and are therefore selected as IHSs. Dioxin TEQ concentrations in all off-property areas are summarized in Table 3-5.

The final off-property TEE showed that surface soil dioxins in portions of off-property areas exceeded site-specific EICs protective of ecological receptors (see Appendix B). Supplemental soil sampling showed that dioxins in the Port Railroad Avenue properties may result in unacceptable ecological risk; however, the remaining off-property areas are not expected to pose an unacceptable risk (see Appendix B).

In summary, off-property IHSs are limited to dioxins.

3.2.2.2 Sampling Results

Fourteen of the off-property soil samples (including one duplicate sample) exceeded the dioxin TEQ Method B CUL of 11 ng/kg: at SS-6, SS-37, SS-38, SS-41 (and duplicate sample) through SS-44, SS-47 through SS-51, and SS-57. Samples SS-46, SS-52 through SS-56, SS-58, and SS-59 did not exceed the Method B CUL; they define the extent of dioxin impacts to the east. The samples collected east and north of Cell 4 were below the Method B CUL. Therefore, the extent of dioxin impacts has been delineated. The results for off-property sample locations (see Figure 3-3) are further summarized below for Port-owned properties and non-Port-owned properties:

- Port Railroad Avenue properties (east of LRIS): The Port owns two parcels located along Railroad Avenue just east of the LRIS. These properties are vacant at this time and are zoned mixed-waterfront use. A potential future use of this area is parking lots (involving commercial grade filling and asphalt capping; see Section 2.8.2). Five soil samples were collected on these parcels. Four of five samples (SS-37, SS-38, SS-41, and SS-42) were above the MTCA B CUL of 11 ng/kg. One sample (SS-42, dioxin TEQ 110 ng/kg) appears to be an outlier and may not be representative, as it was more than twice the concentration measured in an adjacent soil sample (41 ng/kg for SS-37) and any of the other samples tested from these properties or the adjacent right-of-way. The fifth soil sample (SS-39 at 5.3 ng/kg) is below the MTCA B CUL. The median dioxin TEQ in these parcels, excluding the outlier sample, is 21 ng/kg.
- Port marina property (south of LRIS): The soil sample (SS-6; 37 ng/kg dioxin TEQ) collected on this property exceeded the MTCA B CUL.
- Port proposed overpass property (south of the LRIS): The soil sample (SS-50; 34 ng/kg dioxin TEQ) collected on this property exceeded the MTCA B CUL.
- McCuddy's Marina (south of LRIS): Three soil samples were collected on the marina property. Dioxin TEQs in surface soils ranged from 2.3 ng/kg to 13 ng/kg. The median dioxin TEQ in these areas is 3.2 ng/kg.
- RNWR property (north of LRIS): Three soil samples were collected north of Cell 4; dioxin TEQs for these samples ranged from 6.5 ng/kg to 9.5 ng/kg. These concentrations are below the Method B CUL of 11 ng/kg and indicate limited, if any, impacts north of the LRIS property.

- Residential areas (east of LRIS): Sixteen samples were collected in the remaining off-property areas in the rights-of-way east of the LRIS. The measured dioxin TEQ in these samples ranged from 0.49 ng/kg to 57 ng/kg. The median dioxin TEQ in these areas is 5.2 ng/kg. Soils more representative of potential human health exposure points in this area (e.g., soil concentrations in yards) have not been characterized.

In summary, wood-treatment chemicals associated with historical Port operations are largely undetected or occur at levels below IHS criteria in upland off-property areas. Dioxins are identified as off-property IHSs, but the most elevated concentrations are largely limited to the Port Railroad Avenue properties. Additional soil characterization in areas representing probable human health exposure points may be conducted for non-Port-owned properties (e.g., yards in residential areas). To further characterize ecological risk, dioxin concentrations in soil were characterized by collecting and analyzing composite samples in September 2012. Dioxin concentrations in off-property areas, excluding the Port Railroad Avenue properties, are not expected to pose unacceptable risk to ecological receptors (see Appendix B).

3.3 Groundwater

The nature and extent of groundwater impacts in the Site were evaluated using data collected from groundwater monitoring wells, SER extraction wells, and reconnaissance groundwater samples. Figure 2-12 shows the location of active monitoring wells as of January 2012, Table 2-1 summarizes the monitoring well completion details for active and decommissioned monitoring wells and piezometers that have been used to evaluate groundwater conditions, and Table 2-2 summarizes well completion details for extraction and injection wells. Reconnaissance groundwater samples used to evaluate the extent of groundwater impacts include those from locations throughout the LRIS, the southern part of the RNWR Carty Unit, and east of the LRIS and Lake River in the RNWR River "S" Unit.

Groundwater investigations conducted in Cell 4 and in the RNWR "S" Unit (across Lake River from the LRIS) confirm that these areas are not impacted (MFA, 2007, 2010e, 2011a). Therefore, groundwater in Cell 4 and in the RNWR "S" Unit is not discussed further in the nature and extent section or in the CSM.

IHSs were detected in groundwater in the UWBZ in Cells 1, 2, and 3. The LWBZ was not investigated in Cell 3 because of the presence of the aquitard that limits downward migration of contamination. Further, IHS concentrations were low in Cell 3 relative to groundwater collected in Cells 1 and 2. The LWBZ was investigated in Cells 1 and 2 because in Cell 2 an area exists where an aquitard is not present and downward migration has the potential to occur. In Cell 1 an aquitard is present but was compromised by wells that were installed by PWT and screened through the aquitard connecting the UWBZ and LWBZ.

Groundwater sampling has also shown that there are two distinct plumes on the LRIS, as shown in Figures 3-4 through 3-13 (note that the locations of the extraction wells are discussed in Section 4.2 and the locations of the remaining wells are shown in Drawing 1). One plume is beneath Cell 3 and is limited to the UWBZ, and the other is beneath Cells 1 and 2 in the UWBZ and LWBZ and extends into the southern portion of the RNWR Carty Unit. The plumes are separated laterally, as shown in Figures 3-4 through 3-14. Further, the plumes are separated vertically, as the impacts in Cell 3 are limited to the UWBZ and the closest impacts in Cell 2 occur in the LWBZ (at MW-62). Therefore, the description below of the nature and extent of groundwater impacts is presented separately for each plume (i.e., "Cells 1 and 2" plume and "Cell 3" plume).

Regularly scheduled groundwater monitoring has been conducted on the LRIS since 2002, typically during the high- and low-water events in January and August, respectively. Historically, monitoring was conducted semiannually for most wells, with a few wells sampled approximately every 18 months (in either January or August). Table 3-6 shows the sampling schedule through August 2012. Groundwater sampling was conducted in a manner consistent with the Ecology-approved field sampling plan (MFA, 2004, Vol. III). Groundwater samples from the Site were analyzed for SVOCs, including PAHs and chlorinated phenolics, using USEPA Method 8270D; for VOCs, using USEPA Method 8260B; for dissolved metals (arsenic, chromium, copper, and zinc), using USEPA Methods 6010/6020; and/or for petroleum hydrocarbons, using NWTPH-Dx.

Since August 2012, groundwater sampling has been conducted at the POC monitoring wells shown on Figure 2-12, and the samples analyzed for the IHSs shown in Table 3-7. The POC monitoring wells are sampled semiannually, in January and August. Note that during interim action construction activities, well MW-59 was damaged and had to be decommissioned. MW-59 was planned as a POC (MFA, 2012c); however, Ecology agreed that the remaining wells would be sufficient to monitor groundwater conditions, and a replacement for MW-59 was not required (Ecology, 2012c). Monitoring results through August 2011 generally show that IHSs are stable or declining throughout the LRIS (MFA, 2012c). The greatest change has occurred in wells located in or around the SER treatment area.

3.3.1 Evaluation of Extent

The nature and extent of groundwater impacts, as shown on Figures 3-4 through 3-13, were evaluated using the data described above by creating 3-D renderings using trendplots (see Appendix I) and EVS, which uses kriging (i.e., a geostatistical method of estimating concentrations, based on spatially limited data) to estimate concentrations beyond the sampling locations. For each node, the kriging parameters were a reach of 4,467 feet and were calculated using the closest 20 sample points. The adaptive gridding concept honors all measured data directly. The confidence bound tolerance is set to 10, which produces results within one order of magnitude of the "true value" (for reference, a confidence bound tolerance set at 1 would produce absolutely certain results and a confidence bound tolerance set at 100 would result in confidence within two orders of magnitude). All groundwater monitoring wells, extraction wells, and reconnaissance groundwater sample points used to create the renderings are shown on Figure 3-14. The monitoring point locations are also shown on Drawing 1.

The modeling uses data points throughout the UWBZ and LWBZ. The model interprets concentrations through the aquitard between the UWBZ and LWBZ beneath Cell 1 and the eastern portion of Cell 2. Monitoring wells are not installed in the aquitard because it does not produce sufficient water for sampling. While the aquitard limits downward migration, it is composed of silt, sand, and gravel and does allow some groundwater to slowly migrate downward from the UWBZ to the LWBZ. On the western portion of Cell 2, the aquitard is absent and the UWBZ and LWBZ are in communication. Because of the presence of the aquitard beneath Cell 3 and the relatively low levels of contamination, modeling was limited to the UWBZ (see Section 3.3.4 for further details).

The 3-D model does not extend into the clay of the lower Troutdale Formation. The clay is competent, very stiff, and dry. The lower Troutdale Formation clay was found to be approximately 40 feet thick, which greatly limits the potential for groundwater migration. A groundwater sample collected beneath the clay, in GP-14 on the RNWR, was non-detect for IHSs.

The results used to complete the modeling include the SER groundwater monitoring results from November 2011 (see Appendix J-1); monitoring well data collected in August 2011 (see Tables 3-8 through 3-16); and reconnaissance groundwater results collected on the LRIS during May and June 2009 and from the RNWR in September 2006 (see Appendices J-2 and J-3, respectively). Note that the reconnaissance sample from GP-14 at 180 feet bgs is included in the tables in Appendix J, but that value is not used in the EVS modeling. The 180-foot-bgs sample from GP-14 shows that the CRBG was not impacted. The arsenic distribution shown (see Figures 3-9 and 3-10) is for the dissolved fraction from monitoring well data only and does not include reconnaissance well groundwater samples. Reconnaissance sample results were excluded because the samples were analyzed for total metals and had relatively high turbidity. The most widespread and/or toxic of the IHSs in groundwater were modeled: benzene, PCE, naphthalene, arsenic, and PCP. The extent of the other IHSs falls within the extent of these five IHSs. The images on Figures 3-4 through 3-13 show different concentration gradients relative to the extent of the Method B groundwater CULs, the Method A groundwater CULs (i.e., for arsenic), and the draft Method B groundwater screening levels for vapor intrusion (SL_v) for VOCs (i.e., benzene, naphthalene, and PCE) exceedances. Figure 3-14 shows the groundwater data points used to create the groundwater images.

Analytical results were compared with MTCA Method B groundwater CULs. However, Method B CULs are not available for petroleum hydrocarbons; therefore, MTCA Method A groundwater CULs were compared to petroleum-hydrocarbon concentrations. Arsenic occurs naturally at concentrations above MTCA Method B CULs in groundwater in Washington State. Taking into account naturally occurring arsenic in groundwater, Ecology calculated the MTCA Method A groundwater CUL and Washington State maximum contaminant level of 5 micrograms per liter (μg/L) for arsenic, based on background concentrations. Therefore, arsenic concentrations are also compared with the Method A CUL, which accounts for concentrations of arsenic expected in groundwater under natural conditions.

As shown through conservative fate and transport modeling (see Section 5.2.3), groundwater impacts are not expected to negatively affect Lake River or Carty Lake; therefore, data are not compared with surface water criteria in this section.

3.3.2 IHSs

The following analytes have exceeded their respective CULs in samples collected from monitoring wells and extraction wells and are generally considered IHSs (MFA, 2007, 2011a):

- **Chlorinated phenolics:** 2,3,4,6-tetrachlorophenol, 2,4,5-trichlorophenol, 2,4,6-trichlorophenol, and PCP
- **cPAHs:** cPAH TEQ
- **Noncarcinogenic PAHs:** acenaphthene, anthracene, fluoranthene, fluorene, 2-methylnaphthalene, naphthalene, and pyrene
- **SVOCs:** bis(2-ethylhexyl) phthalate (BEHP), carbazole, and dibenzofuran
- **VOCs:** acetone, benzene, chloromethane, dichlorodifluoromethane, cis-1,2-dichloroethene, ethylbenzene, hexachlorobutadiene, naphthalene, styrene, 1,1,2,2-tetrachloroethane, PCE, 1,1,2-trichloroethane, trichloroethene (TCE), 1,2,3-trichloropropane, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, vinyl chloride, m,p-xylene, toluene, and o-xylene
- **Dissolved metals:** arsenic and chromium
- **Petroleum hydrocarbons:** DROs and RROs

3.3.3 Cells 1 and 2 Plume

The concentrations of IHSs are generally consistent over time, except for those wells in or near the SER that show large reductions. Some of the groundwater IHSs were detected only in the SER area where NAPL was present, and have not been observed in areas outside the treatment area. The most widespread and/or toxic of the IHSs in groundwater in the Cells 1 and 2 plume are benzene, PCE, naphthalene, arsenic, and PCP. Appendix I-1 shows trend plots for the Cells 1 and 2 plume monitoring wells. Where concentrations significantly exceeded CULs (e.g., ten times the Method B groundwater CUL), the concentration gradients are displayed on the images.

A detailed description of the nature and extent of the Cells 1 and 2 plume is presented in the Cells 1 and 2 RI/FS (MFA, 2011a); a brief description is provided below.

3.3.3.1 VOCs

VOCs historically have been detected at higher frequencies in the SER area, but the SER system has removed many of the VOC IHSs to below Method B CULs. The highest remaining concentrations of VOCs in the Cell 2 area generally are found in the former concrete pond area. The chemicals in the Cells 1 and 2 plume area that most frequently exceeded the Method B groundwater CUL were benzene, naphthalene, PCE, TCE, and vinyl chloride. The remaining VOC IHSs generally exceeded Method B groundwater CULs in 10 percent or less of the samples (MFA, 2011a).

3.3.3.2 PAHs

PAHs were detected at much higher frequencies and concentrations in the SER area than VOCs (MFA, 2011a). The higher concentrations of PAHs in the SER area likely are related to the presence of NAPL and the heat generated by the SER system. cPAHs are seldom detected in groundwater samples outside the SER area. Naphthalene is the most widespread of the PAH IHSs; therefore, the nature and extent of naphthalene were modeled.

Figures 3-7 and 3-8 show the extent of the naphthalene plumes on the LRIS and a cross section from east to west.[2] Note that naphthalene does not exceed CULs in Cell 3.

3.3.3.3 Dissolved Metals

Copper and zinc either are not detected or are detected below CULs in groundwater samples (MFA, 2011a). Arsenic is often detected in groundwater samples from monitoring wells, especially in the shallow UWBZ. Figures 3-9 and 3-10 show the extent of the dissolved arsenic plume on the LRIS and a cross section from east to west. Note that arsenic exceeds CULs beneath Cell 3 but is not connected with the impacts on Cells 1 and 2. Arsenic impacts in Cell 3 are discussed below in Section 3.3.4.

3.3.3.4 Chlorinated Phenolics

Chlorinated phenolics were detected historically at much higher frequencies and concentrations in the SER area than elsewhere (MFA, 2011a). The higher concentrations of phenolics in the SER area likely were related to the presence of NAPL and the mobilization of chemicals resulting from the heat generated by the SER system. Only two chlorinated phenolics have been detected outside the SER area above Method B groundwater CULs: 2,4,6-trichlorophenol and PCP, of which PCP is the more widespread. Figures 3-11 through 3-13 show the extent of the dissolved PCP plume and present three cross sections. Note that PCP exceeds CULs beneath Cell 3, but the impacts are not connected with the impacts in Cells 1 and 2. PCP impacts in Cell 3 are discussed below in Section 3.3.4.

The highest concentrations of PCP are observed in and just downgradient of the known source, the former tank farm area. Higher concentrations historically occurred in the tank farm area, but the SER system has reduced contaminant levels. PCP is detected almost exclusively in the shallow UWBZ in the former tank farm area. Shallow UWBZ groundwater samples collected near the former concrete pond showed minimal PCP impacts (e.g., PCP was detected in well MW-26 six out of 18 times since January 2004, averaging 8.25 μg/L in those six samples). Therefore, it appears that the former concrete pond is not a significant source of PCP. The PCP detected in the deep UWBZ (e.g., MW-52D at an average concentration of 311 μg/L) and the LWBZ (e.g., MW-35 at an average concentration of 2,321 μg/L) in the area of the former concrete pond likely is the result of migration from the former tank farm and retort area. The PCP plume extends just beyond the western and northern property boundaries under Lake River and Carty Lake, but as shown in the cross sections, the plume does not intersect the water bodies. Rather, it flows beneath them and attenuates before reaching the eastern bank of Lake River. In addition, groundwater modeling indicates that if the

---

[2] Naphthalene is a PAH, but, because it is volatile, is also analyzed as a VOC. Results from the VOC analyses are generally slightly higher than results from PAH analyses for naphthalene. The VOC analytical results for naphthalene were used in the modeling.

deep UWBZ discharged to Lake River or Carty Lake, PCP would not adversely impact groundwater (see Section 5.2.3).

3.3.3.5 SVOCs

Three SVOCs other than PAHs and chlorinated phenolics exceed CULs: BEHP, carbazole, and dibenzofuran. BEHP is not detected frequently, but it is most frequently detected in three monitoring wells in the RNWR, USDFW-1 through USDFW-3 (see Table 3-9). BEHP is not generally detected in monitoring wells in Cells 1 and 2 and is not believed to be related to LRIS sources. Monitoring wells USDFW-1 through USDFW-3 have dedicated pumps with dedicated plastic tubing. BEHP is a component of plastic; therefore, the BEHP detections could be the result of the dedicated plastic tubing. The fate and transport of BEHP were evaluated because of its presence above surface water criteria (see Section 5.2.3). The results of the modeling indicate that BEHP will not adversely affect surface water bodies.

Carbazole and dibenzofuran are detected throughout the LRIS, but are not as widespread as other IHSs, such as PCP or naphthalene. Fate and transport modeling of dibenzofuran were completed because it exceeded surface water criteria adjacent to Lake River and Carty Lake. The modeling indicated that dibenzofuran will not negatively impact the surface water bodies (see Section 5.2.3).

3.3.3.6 Petroleum Hydrocarbons

Petroleum hydrocarbons such as DROs and RROs are detected frequently at the LRIS and often exceed the Method A groundwater CULs. DROs are detected more frequently than RROs. The DRO extent is similar to those of PCP and naphthalene.

3.3.3.7 Dioxins

Dioxins have a high affinity to adsorb to soil particles and are relatively insoluble. However, because NAPL was in contact with groundwater, dioxins may have impacted groundwater. Therefore, on August 21, 2008, during a semiannual sampling event, samples from monitoring wells MW-38, MW-39, MW-56, and USDFW-1 were analyzed for dioxins, as requested by Ecology (Ecology, 2008b). The results of the monitoring were provided to Ecology (MFA, 2009).

The groundwater dioxin TEQs ranged from 13 picograms per liter (pg/L) (MW-56) to 29 pg/L (MW-39) (see Table 3-12). TCDD was not detected and the reporting limits were below the maximum contaminant level of 30 pg/L for TCDD. MTCA does not have a CUL for dioxins or TCDD in groundwater.

While dioxins are present in groundwater, the concentrations near the property boundaries do not exceed the maximum contaminant level. Further, the dioxin congeners that are detected (i.e., 1,2,3,4,6,7,8,9-octachlorodibenzo-p-dioxin and 1,2,3,4,6,7,8,9-octachlorodibenzofuran) are typically the least toxic congeners.

3.3.4 Cell 3 Plume

Conditional POC sampling in Cell 3 is currently conducted as described in the groundwater results letter (MFA, 2012c). POC monitoring wells (i.e., MW-29D, MW-45D, MW-46S, MW-46D, and MW-47D) are sampled and analyzed for specific IHSs historically identified in groundwater samples at the riverbank: PCP, arsenic, and/or PCE (see Table 3-7). Tables 3-13 through 3-16 summarize groundwater analytical results for monitoring wells in Cell 3 since 2004. Appendix I-2 includes trend plots for PCP (MW-45D), PCE (MW-45D, MW-46D, and MW-47D), and dissolved arsenic (MW-46S). Figures 3-5 and 3-6 (PCE), 3-9 and 3-10 (arsenic), and 3-11 through 3-13 (PCP) show the nature and extent of and cross section from east to west. Note that as discussed above, the Cell 3 UWBZ plume is separated from the Cell 2 plume vertically and laterally. The LWBZ in Cell 3 was not investigated because of the relatively low concentration of IHSs in the UWBZ and because the aquitard is continuous and significant downward migration is not expected.

PCP in Cell 3 is in the deep UWBZ downgradient of the former drip trough and extends just beyond the property boundary under Lake River, but as shown in the cross section, the plume does not intersect the water body (see Figures 3-11 through 3-13). Rather, the plume flows beneath it and attenuates before reaching the eastern bank of Lake River. In addition, groundwater modeling indicates that if the deep UWBZ discharged to Lake River, PCP would not be present (see Section 5.2.3).

PCE typically is detected in the deep UWBZ monitoring wells, except for MW-20D. Concentrations vary but show an overall stable or slightly declining trend; however, there was a slight increase in concentration from January 2010 to August 2011 (see Table 3-15). Concentrations of PCE in the deep portion of the UWBZ generally decrease to the west and north across Cell 3 (see Figures 3-5 and 3-6). The plume extends just beyond the western property boundary under Lake River, but as shown in the cross section and through groundwater transport modeling (Section 5.2.3), the plume does not intersect Lake River. Rather, it flows beneath Lake River and attenuates before reaching the eastern bank of the lake.

PCE concentrations exceed the groundwater SL_v of 1 μg/L on portions of the LRIS. However, the impacts are deep and do not extend to the shallow UWBZ. For PCE to impact soil vapor concentrations, the impacts would have to migrate to the surface of the water table.

It appears that the source of the PCE in Cell 3 is a former dry cleaner located in downtown Ridgefield. This presumed source area is approximately 690 feet east (upgradient) of Cell 3. A dry cleaner (Park Laundry) reportedly operated at 122 North Main Avenue from 1964 to 1980. An ongoing investigation being conducted by MFA (MFA, 2012b) shows groundwater impacts extending in the UWBZ from the source to Cell 3. Figures 3-5 and 3-6 do not show the plume extending southeast, toward Park Laundry, because off-site Park Laundry data were not used in the model.

The highest concentrations of arsenic are observed just downgradient of known sources (i.e., the former drip trough) in the shallow UWBZ. Arsenic in some areas may be the result of site impacts, while in other areas it may be the result of natural geologic conditions. The arsenic plume appears to intersect Lake River; however, the conservative fate and transport modeling presented in Section 5.2.3 indicates that arsenic above the Method A groundwater CUL will not reach Lake River.

3.3.5 IHS Trends

3.3.5.1 Cells 1 and 2

Concentrations of IHSs in most wells in Cell 1, Cell 2, and the RNWR (i.e., the southern portion of Carty Lake) show stable or declining trends. The monitoring wells expressing significant fluctuations of IHS concentrations are in or near the SER system in the UWBZ and LWBZ. Appendix I-1 contains trend plots for the Cells 1 and 2 plume monitoring wells.

Groundwater monitoring data indicate that source control and reduction efforts in the SER area are effective and that concentrations of IHSs in groundwater are generally stable or decreasing. Concentrations of chemicals in groundwater in and near the SER area have greatly decreased because of the operation of the SER system (see Section 4). Concentrations of IHSs outside the active SER area are also generally stable or declining.

3.3.5.2 Cell 3

Concentrations of IHSs in groundwater in Cell 3 show overall stable trends. Attachment E contains IHS trend plots in POC wells for PCP (MW-45D), PCE (MW-45D, MW-46D, and MW-47D), and dissolved arsenic (MW-46S). The IHS trend plots and trends in non-POC wells are discussed below:

PCP concentrations in MW-45D have varied from 120 µg/L (July and October 2004) to 24.2 µg/L (January 2005). PCP concentrations in groundwater from MW-45D show an overall decreasing trend. PCP was also detected in other wells infrequently (i.e., MW-9S and MW-29D) or during a single event (i.e., MW-20S, MW-28S, MW-20D, and MW-46D). The only other SVOCs detected above CULs were cPAHs, 1-methylnaphthalene, and carbazole. Those SVOCs were infrequently detected and typically were found in MW-9S, in the interior of Cell 3.

PCE typically is detected in the deep UWBZ monitoring wells. Concentrations vary but show an overall stable or slightly declining trend; however, there was a slight increase in concentration from January 2010 to August 2011. Concentrations of PCE in the deep portion of the UWBZ generally decrease to the west and north across Cell 3. As described above, it appears that PCE is migrating onto Cell 3 from an upgradient source. No other VOCs were detected above CULs, except for benzene only, in MW-9S during one event.

Concentrations of dissolved arsenic in groundwater from MW-46S vary and show no overall trend. Concentrations have varied from 56 µg/L (January 2007) to 11.0 µg/L (October 2005). Arsenic was also typically detected above Method A CULs in MW-9S and MW-45S. Concentrations in MW-45S showed an overall decreasing trend, and only one of the last six sampling events detected arsenic over the Method A CUL. Arsenic in MW-9S samples showed an overall stable trend, with concentrations generally around 50 to 60 µg/L.

The trends described above show that concentrations of IHSs are generally stable or declining.

3.4 Stormwater Monitoring

In 2002, Ecology issued an industrial stormwater general permit for the LRIS (National Pollutant Discharge Elimination System [NPDES] permit number SO3-00-1835). This permit required the Port to monitor each of the four stormwater outfalls (OF-1, OF-2, OF-3, and OF-4) quarterly for turbidity, pH, zinc, oil and grease, copper, lead, hardness, and biological oxygen demand. Note that other parameters not included in the NPDES permit (e.g., PCP, benzo(a)pyrene) were analyzed in stormwater, based on Ecology's verbal request. Ecology reissued the industrial stormwater general permit on October 21, 2009, effective January 1, 2010 (NPDES Permit No. WAR001835E), eliminating oil and grease, hardness, and biological oxygen demand as required parameters.

Stormwater monitoring was incorporated into the site-specific NPDES permit WA 0041025, issued August 1, 2010, which also permitted the discharge from the SER system. The permit required monthly monitoring at OF-1 through OF-4 for PCP, benzo(a)pyrene, total zinc, total suspended solids, and pH.

Outfalls OF-5 and OF-6 were constructed in 2010 as part of the Cells 3 and 4 interim action. OF-1 through OF-4 were decommissioned (see Section 4.4) and OF-7, OF-8, and OF-9 were installed during 2012 as part of the Cells 1 and 2 interim action. Outfalls OF-7, OF-8, and OF-9 have not yet been sampled, as the drainage area is still under construction.

Stormwater data collected through January 2012 from outfalls OF-1, OF-2, OF-3, OF-4, OF-5, and OF-6 are included in Table 3-17. Figure 2-16 shows the historical stormwater configuration, and Figure 2-17 shows the current stormwater configuration as of January 2012.

Parameters include IHSs (e.g., arsenic, PCP, benzo(a)pyrene) and additional parameters that were required under NPDES permit monitoring (e.g., pH, total suspended solids, hardness). Data were screened against four criteria: USEPA water quality criteria (WQC) freshwater criterion continuous concentration (CCC), MTCA Method B surface water CULs, USEPA WQC human health (HH) consumption of organisms and water, and USEPA WQC HH consumption of organisms only.

The relevant IHS stormwater monitoring (i.e., metals, benzo(a)pyrene, PCP) are discussed below.

3.4.1 Metals

Dissolved zinc typically exceeded the WQC freshwater CCC at OF-4. Historically, OF-2 regularly exceeded the zinc screening criteria; however, since 2009 concentrations have generally been below the screening criteria. OF-3 samples periodically exceeded the dissolved zinc WQC freshwater CCC. Zinc concentrations at OF-2 and OF-4 exceeded surface water criteria as recently as 2010. OF-5 and OF-6 have not detected zinc above screening criteria.

Dissolved arsenic at OF-2 typically was not detected above MRLs. Detections typically exceeded WQC HH consumption of organisms and water and WQC HH consumption of organisms only. Dissolved arsenic at OF-3 and OF-4 typically was detected above WQC HH consumption of organisms and water and WQC HH consumption of organisms only. However, most of the recent dissolved arsenic concentrations in stormwater (i.e., collected from 2007 through 2010) were below concentrations generally associated with background levels in groundwater in Washington State.

Dissolved chromium exceeded the hexavalent chromium WQC freshwater CCC once: in OF-2 in 1997. Several exceedances of this criterion were observed in samples collected at OF-3 in 1998, 2003, and 2004. This criterion is a conservative comparison, as the data are based on nonspeciated chromium analysis, not hexavalent chromium analysis. Stormwater samples collected since 2004 have not exceeded this conservative criterion.

Exceedances of the dissolved copper WQC freshwater CCC were observed at OF-2 from 1997 to 2000 and once in 2008. No exceedances of the WQC freshwater CCC have been observed at OF-3 since 2006. Dissolved copper typically exceeded the WQC freshwater CCC in OF-4 from 1997 to 2000. Four exceedances were observed at OF-4 between 2003 and 2008. Stormwater samples collected since 2008 have not exceeded copper surface water criteria.

Dissolved lead exceeded the WQC freshwater CCC in 1997 (once at OF-2 and twice at OF-3) and in 2003 (twice at OF-3). No exceedances were observed at OF-4. Dissolved lead concentrations have not exceeded surface water criteria since 2003.

3.4.2 Benzo(a)pyrene

Benzo(a)pyrene typically is not detected above MRLs; however, the MRLs are higher than several screening criteria. When benzo(a)pyrene was detected at OF-2, OF-3, and OF-4, the concentrations exceeded the following criteria: WQC HH consumption of organisms and water, WQC HH consumption of organisms only, and the MTCA Method B surface water CUL.

3.4.3 Pentachlorophenol

PCP has exceeded one or more screening criteria in samples from OF-1, OF-2, OF-3, and OF-6. While concentrations have steadily decreased over time, recently collected samples (i.e., 2011 and 2012) continue to exceed the lowest of the surface water criteria for PCP and the USEPA WQC HH consumption of organisms and water of 0.3 μg/L.

One sample from OF-6 in December 2010 detected PCP. PCP has not been detected in stormwater samples since then.

3.5 Sediment

This section summarizes the results of sediment chemical and physical testing performed at Lake River and Carty Lake. Data were collected during the RI in April 2010, and results were reported in the sediment memorandum (Anchor and MFA, 2011). Sediment samples collected in 2010 were submitted for analysis of LRIS IHSs (PCP and associated chlorinated phenolics, PAHs, metals [arsenic, chromium, copper, and zinc], and dioxins). In addition, at the request of Ecology, selected sediment samples were submitted for parameters, including polychlorinated biphenyls, TPH, ammonia, grain size, and TOC. Additional Carty Lake sampling was performed in September 2011 and reported in the Supplemental Carty Lake Sediment Sampling Results report (MFA, 2012a);

samples were analyzed for dioxins, grain size, and TOC at the direction of Ecology. Sediment preliminary screening criteria are identified below and are compared with sediment concentrations in Lake River and Carty Lake to identify hazardous substances in sediment.

3.5.1 Sediment Screening Criteria

The goal of SMS (WAC 173-204) is to reduce and ultimately eliminate adverse effects on biological resources and threats to human health from surface sediment contamination. Ecology does not currently have freshwater sediment screening criteria, and freshwater sediment standards are currently set on a case-by-case basis. Because the SMS rule regulates sediments based on benthic toxicity, recently developed freshwater sediment quality values based on benthic toxicity described by Avocet Consulting (2011) are used to screen sediments. These values were developed for Washington, Oregon, and Idaho, and represent the current state of the science for sediment values that are representative of possible toxicity, with the use of the floating percentile method to provide a reasonable/conservative evaluation of chemical concentrations that could predict toxicity. Two levels of benthic criteria were developed, corresponding to the SMS narrative sediment quality standard and the cleanup screening level/minimum CUL. The more protective benthic criteria, when available, were compared with sediment concentrations to identify hazardous substances. In addition, data were screened against consensus-based probable effect concentrations (PECs) developed to predict sediment toxicity (MacDonald, Ingersoll, and Berger, 2000). Tables 3-18 and 3-19 show the Lake River screening results and Table 3-20 shows the Carty Lake screening results (see Figures 3-15 and 3-16 for screening criteria exceedances in Lake River and Carty Lake, respectively).

To assess potential adverse effects on aquatic receptors and on the wildlife that consume them, the Oregon Department of Environmental Quality (DEQ) developed screening level values (SLVs) protective of ecological receptors exposed to bioaccumulative chemicals (DEQ, 2007). Constituents for which default SLVs are available (i.e., PCP and dioxins) were compared with sediment concentrations. Tables 3-18 and 3-19 (Lake River) and Table 3-20 (Carty Lake) show the results of the bioaccumulative screening for ecological receptors.

In addition to protecting benthic and ecological receptors, MTCA/SMS regulations require protection of human health. Impacts to human health may result from exposure to bioaccumulative chemicals; these compounds have the potential for trophic transfer to higher-level organisms that humans may consume. Specific approaches for human health are not currently available, as the rule is being revised but is not yet promulgated. The approach provided in the DEQ bioaccumulative guidance (DEQ, 2007) is used to evaluate bioaccumulative chemicals (PCP and dioxins) in sediment with respect to human health risk.

For PCP, the default DEQ bioaccumulation SLV of 250 μg/kg protective of human consumption of fish was used to screen sediment concentrations (DEQ, 2007). For dioxins, levels in sediments considered protective of human health are typically very low because of both bioaccumulative potential and low effects levels. Modeling sediment concentrations of a group of chemicals (e.g., multiple dioxin congeners) that is protective of higher trophic levels is complex because each congener varies in its bioaccumulative potential. As a result of the low toxicity values and complexities associated with bioaccumulation modeling for groups of chemicals, CULs are frequently based on background conditions.

Ecology is currently developing methods for defining natural background and regional background concentrations for sediments, and its strategy for management of low-level bioaccumulatives is expected to be implemented over the coming decades. Currently, CULs typically defer to background concentrations. Therefore, the Lower Columbia River dioxin TEQ natural background concentration (2 ng/kg; see Appendix K for derivation) was used to screen dioxins in sediment. Dioxins (measured as TEQs) were compared to the Columbia River background concentration, as shown in Tables 3-18 and 3-19 for Lake River and in Table 3-20 for Carty Lake (see Figures 3-15 and 3-16 for screening criteria exceedances in Lake River and Carty Lake, respectively).

In screening evaluations, half of the estimated detection limit was compared to screening criteria when data were qualified as U or UJ. For further details on data validation and the TEQ calculation methodology used for dioxin screening, see Appendix F.

The screening criteria approach described above supports initial identification of hazardous substances in sediment. WAC 173-340-703 states that when cleanup requirements are being defined for a site that is contaminated with a large number of hazardous substances, those hazardous substances that contribute a small percentage of the overall threat to human health and the environment may be eliminated from consideration, and the remaining hazardous substances shall serve as IHSs for purposes of defining site cleanup requirements. Other risk-based criteria and CULs relevant to Lake River and Carty Lake are developed in Section 6 of this RI/FS report.

3.5.2 Lake River

Surface sediment was collected from the presumed biologically active zone of 0 to 10 centimeters (cm) bml at 28 Lake River locations. Thirty surface samples (including two duplicate samples) were tested to delineate the lateral extent of sediment impacts. One surface sample was collected offshore of the City stormwater outfall approximately 900 feet upstream (south) of the LRIS to characterize potential nearby sources of chemicals. Subsurface sediment was collected in nine locations at depths of 1 to 2, 3 to 4, 4 to 5, 5 to 6, or 9 to 10 feet bgs to delineate the vertical extent of sediment impacts. Surface and subsurface sample locations were selected to characterize areas suspected to be highly impacted (e.g., just offshore of former outfalls) and to delineate the boundaries of sediment impacts relative to preliminary sediment screening criteria (see Figure 3-15). In addition, three samples were collected (two in Lake River and one in Bachelor Slough) to characterize local background conditions in surface sediment (Anchor and MFA, 2011; note that Appendix K presents the findings of an evaluation of natural background conditions in regard to dioxins in sediment in the Lower Columbia River).

3.5.2.1 IHSs

The results of sediment testing and screening are summarized in Tables 3-18 and 3-19. Figure 3-15 shows screening criteria exceedances in Lake River.

Sediment results and identification of IHSs in Lake River are described below:

- There were no exceedances of Avocet benthic screening criteria and PECs for chemicals detected in surface sediment samples.

- Dioxins: concentrations of dioxins in surface samples, reported as dioxin TEQs, ranged from 0.51 to 580 ng/kg, with exceedances of background (2 ng/kg) occurring primarily in LRIS offshore areas. Dioxins are identified as an IHS.

  The lateral extent of dioxin impacts is well-defined. Dioxin TEQs were highest along the LRIS nearshore areas and significantly decreased farther from shore. Concentrations also decreased to the north, approaching the LRIS northern property boundary. Surface sediment concentrations to the south of the LRIS (i.e., south of LRIS-LR-19) decreased significantly at LRIS-LR-18 (1.7 ng/kg) and LRIS-LR-17 (4.3 ng/kg), but then increased at LRIS-LR-16 (14 ng/kg), which is just offshore of the City stormwater outfall (see Figure 3-15).

  The highest surface sediment dioxin TEQ (580 ng/kg) was detected in LRIS-LR-09, just offshore the LRIS and OF-4 and near LRIS-LR-08, where concentrations of dioxins were also high. Other chemicals were also above screening levels in these two samples. Concentrations at LRIS-LR-09 are bounded vertically (<5 ng/kg at 1 to 2 and 4 to 5 feet bml) and laterally to the west at LRIS-LR-23 and to the southwest at LRIS-LR-07.

  Subsurface sediment dioxin TEQ concentrations were highest at LRIS-LR-08, which is offshore of OF-4, and at LRIS-LR-10, which is offshore of OF-2. LRIS-LR-08 (1 to 2 feet bml) had a dioxin TEQ of 910 ng/kg; the concentration decreased substantially to 6.9 ng/kg in the deeper 3- to 4-foot-bml interval. To the north of LRIS-LR-08, LRIS-LR-10 had a dioxin TEQ of 79 ng/kg in the 1- to 2-foot-bml interval. The other nearshore subsurface sediment dioxin TEQ results were much lower and ranged from 6.4 ng/kg (LRIS-LR-01, adjacent to OF-1) to 17 ng/kg (LRIS-LR-05, adjacent to the former barge-loading area).

  Exceedances of dioxin congener SLVs protective of ecological receptors were generally colocated with elevated dioxin TEQs (see Tables 3-18 and 3-19). LRIS-LR-08 and LRIS-LR-09 had the most dioxin congener ecological SLV exceedances (12 and seven exceedances, respectively) and also had the highest dioxin TEQs.

- PCP: PCP exceeded Avocet benthic criteria at one subsurface location (LRIS-LR-08). No PEC is available for PCP. The 3,100-μg/kg PCP exceedance of the Avocet benthic criteria was limited to the shallow subsurface (1 to 2 feet bml) and is vertically bound at 3 to 4 feet bml (22 μg/kg). Elevated subsurface PCP at LRIS-LR-08 is consistent with historical stormwater discharge of wood-treating chemicals from OF-4.

  Slightly elevated PCP surface concentrations above the ecological bioaccumulation SLV criterion of 310 μg/kg and the human consumption bioaccumulation SLV of 250 μg/kg (but below benthic criteria) are found at LRIS-LR-24 (510 μg/kg), adjacent to LRIS-LR-08; at LRIS-LR-25 (740 μg/kg) near OF-3; and at LRIS-LR-19 (380 μg/kg) and LRIS-LR-20 (490 μg/kg) near OF-5 and OF-6, again suggesting stormwater inputs as a primary PCP transport pathway to Lake River.

  Where elevated PCP occurs, it is colocated with elevated dioxins (see Figure 3-15), and any remedial action developed for dioxins is therefore expected to address elevated PCP.

For example, the maximum PCP detection occurs in the subsurface at LRIS-LR-08, where the dioxin TEQ is also most elevated. PCP exceedances in other samples were marginally above screening criteria, were below screening criteria, or were non-detect. PCP therefore was not selected as an IHS.

- M&p-cresol: m&p-cresol (3- and 4-methylphenol) exceeded the Avocet benthic criterion for 4-methylphenol (260 μg/kg) at one subsurface location (LRIS-LR-09) in two sample intervals: 1 to 2 feet bml (360 μg/kg) and 4 to 5 feet bml (280 μg/kg). Elevated m&p-cresol at LRIS-LR-09 is colocated with elevated dioxins (see Figure 3-15) and is consistent with historical stormwater discharge of wood-treating chemicals from OF-4; any remedial action developed for dioxins is therefore expected to address elevated m&p-cresol. M&p-cresol infrequently and marginally exceeded screening criteria and is colocated with elevated dioxins; therefore, m&p-cresol was not selected as an IHS.
- PAHs: total PAHs (TPAH) exceeded Avocet benthic criteria at one subsurface location: LRIS-LR-08 (1 to 2 feet bml); fluorene, phenanthrene, anthracene, fluoranthene, pyrene, chrysene, and benzo(a)anthracene also exceeded PECs at this location. As with PCP, no exceedances occurred in the surface layer or the deeper subsurface (3 to 4 feet bml) at LRIS-LR-08, indicating that the vertical extent of these chemicals is bounded. Other slightly elevated levels (but below screening criteria) are observed at LRIS-LR-25 (TPAH at 4,160 μg/kg) between OF-2 and OF-3. In addition, elevated values at LRIS-LR-19 (TPAH at 2,863 μg/kg) and LRIS-LR-20 (TPAH at 2,237 μg/kg) are adjacent to OF-1; similarly elevated concentrations (but below screening criteria) occur at LRIS-LR-05 and -06. Thus, subsurface PAH exceedances at LRIS-LR-08 and other elevated PAH levels are generally consistent with historical stormwater discharge from the LRIS outfalls.

  Where elevated PAHs occur, they are colocated with elevated dioxins (see Figure 3-15), and thus any remedial action developed for dioxins is expected to address PAHs. For example, the most elevated TPAH and PAH congener detections occur in the subsurface at LRIS-LR-08, where the dioxin TEQ is also most elevated. PAH concentrations in other samples were below screening criteria or were non-detect. PAHs were therefore not selected as an IHS.
- Di-n-octyl phthalate was not detected in any surface or subsurface samples, but a reported non-detect of 110 μg/kg exceeded the Avocet benthic criteria in the surface at LRIS-LR-05; based on no reported detections, di-n-octyl phthalate was not selected as an IHS.

In summary, dioxins were identified as IHSs. Other contaminants exceeding Avocet benthic criteria or PECs were identified only in the subsurface layers at LRIS-LR-08 and LRIS-LR-09, adjacent to OF-4, where the most elevated dioxin concentrations also occur. Slightly elevated concentrations of site-related chemicals in other locations also occurred adjacent to LRIS outfalls, suggesting historical stormwater as the most significant transport pathway for site-related contaminants. Elevated surface dioxin TEQs also occurred primarily near outfalls and tended to decrease with depth.

Ecological SLVs were exceeded in surface and subsurface, but exceedances were limited to the same areas where contaminants exceeded benthic screening criteria or PECs and where there were elevated dioxin TEQs.

Site-related impacts are bounded to the north at LRIS-LR-28 (dioxin TEQ at 0.84 ng/kg) and to the south at LRIS-LR-18, where the dioxin TEQ was 1.7 ng/kg. A slightly elevated dioxin TEQ occurs farther south at LRIS-LR-16 (14 ng/kg), but contamination observed here was discontinuous from the areas of elevated dioxins in sediments adjacent to the LRIS property and likely is related to City stormwater outfall inputs and/or in-water and overwater structures near the sample location (see Section 5.2 and Appendix L for a discussion of potential sources to the City stormwater outfall).

3.5.3 Carty Lake

Eight surface and seven subsurface sediment samples were collected in Carty Lake as part of the RI sampling; results were reported in the sediment memorandum (Anchor and MFA, 2011). In 2011, supplemental sampling was conducted at Ecology's request to more fully delineate the lateral and vertical extent of dioxins in Carty Lake (MFA, 2012a); surface sediment samples were collected at eight locations in Carty Lake. In addition, a subsurface (2 to 3 feet bml) sediment sample was collected at LRIS-CL-02 to define the vertical extent of impacts identified at this location in 2010. Figure 3-16 shows all Carty Lake sediment sampling locations.

3.5.3.1 IHSs

The results of Carty Lake sediment testing and screening are presented in Table 3-20 and Figure 3-16. Results for Carty Lake are summarized below:

- Dioxins are identified as an IHS, based on exceedances of background (2 ng/kg dioxin TEQ). Dioxin TEQs are most elevated in surface sediment in the southern portion of the lake (LRIS-CL-01, -02, and -04 at concentrations of 140 ng/kg, 1,400 ng/kg, and 300 ng/kg, respectively) and decrease substantially within approximately 100 feet (LRIS-CL-03 at 24 ng/kg) and 300 feet (LRIS-CL-05 at 1.8 ng/kg). TEQs in the surface sediment in the rest of the lake are generally consistent and range between 15 ng/kg and 32 ng/kg, with the following two exceptions: one low-level concentration of 1.8 ng/kg (LRIS-CL-13) and one somewhat higher concentration of 54 ng/kg (LRIS-CL-09). The average and median surface sediment dioxin TEQs were 20 ng/kg and 22 ng/kg, respectively, excluding the highly elevated LRIS-CL-01, -02, and -04 samples in the southern portion of Carty Lake. The vertical extent of dioxin impacts is limited; dioxin TEQs in samples collected at 1 to 2 feet bml are generally between 1 and 5 ng/kg, except at the most highly impacted location, LRIS-CL-02, where the 1- to 2-foot-bml sample was 130 ng/kg and the extent is defined at 2 to 3 feet bml at 2.5 ng/kg.

  Multiple dioxin congeners exceeded ecological bioaccumulation SLVs (see Table 3-20); impacts were concentrated in the surface in samples collected at the southern end of the lake at LRIS-CL-01 (three of 17 congeners exceeded), LRIS-CL-02 (ten of 17 congeners exceeded), and LRIS-CL-04 (six of 17 congeners exceeded). Fifteen of 17 dioxin congeners did not exceed ecological SLVs in any other areas of the lake (see Table 3-20). Exceedances in areas north of the impacted southern portion were limited to detected concentrations of 2,3,4,7,8-pentachlorodibenzofuran at LRIS-CL-06 and-07 (in other cases this congener was not detected, but the detection limit exceeded the SLV) and two

TCDD concentrations with minimal exceedances (i.e., 0.1 ng/kg above the SLV) at LRIS-CL-09 and LRIS-CL-15.

- Metals (arsenic and chromium): Arsenic concentrations at LRIS-CL-02 were 48 mg/kg and 15 mg/kg in surface sediment (0 to 10 cm bml) and the subsurface (1 to 2 feet bml), respectively. Arsenic exceeded the PEC (33 mg/kg) in the surface, and exceeded the Avocet benthic criteria of 14 mg/kg in surface and subsurface. The arsenic concentration decreased with depth, suggesting that contamination is vertically bounded. Chromium (86 mg/kg) marginally exceeded the benthic criterion (72 mg/kg) at LRIS-CL-02 surface and also decreased with depth (34 mg/kg at 1 to 2 feet bml) and is vertically bounded.

  Elevated metals are colocated with elevated dioxins (see Figure 3-16), and any remedial action developed for dioxins is expected to address metals. Metal exceedances occur only at LRIS-CL-02, where dioxins are also most elevated. Metals in other samples were below screening criteria and are generally consistent with natural soil background concentrations for arsenic (5.81 mg/kg) and chromium (26.57 mg/kg) for Clark County (Ecology, 1994). Since the limited number of metals exceedances were colocated with dioxins, they were not selected as an IHS.

- Di-n-octyl phthalate was not detected, but an elevated reporting limit of 87 μg/kg exceeded Avocet benthic criteria in the subsurface at LRIS-CL-02; di-n-octyl phthalate was not carried forward as an IHS, as detected concentrations did not exceed benthic criteria.

- PAHs did not exceed screening criteria at any location and were therefore not selected as an IHS.

- PCP exceeded bioaccumulation SLVs protective of ecological receptors and human fish consumption in surface sediment at LRIS-CL-02 but was well below both Avocet benthic and bioaccumulation SLVs at nearby sample locations, bounding the lateral extent of impacts. PCP decreased substantially with depth at LRIS-CL-02, suggesting that vertical extent is bounded; however, the human fish consumption SLV of 250 μg/kg was marginally exceeded in the 1- to 2-foot-bml sample (270 μg/kg). PCP concentrations did not exceed Avocet benthic criteria; a PEC is not available for PCP.

  PCP bioaccumulation SLV and benthic criteria exceedances are limited to one location and are colocated with the highest dioxin concentrations (see Figure 3-16). Remedial actions developed for dioxins are expected to address any potential unacceptable risk resulting from exposure to PCP; therefore, PCP was not selected as an IHS.

In summary, dioxins were identified as IHSs for Carty Lake sediment. Significantly elevated dioxin TEQs are largely limited to the southern portion of the lake and consist of samples LRIS-CL-01, -02, and -04, although elevated (i.e., higher than background of 2 ng/kg) dioxin TEQ concentrations occur at multiple locations; dioxin congener exceedances of ecological bioaccumulation SLVs, where they occur, are colocated with dioxin TEQ exceedances. The spatial distribution of impacts is consistent with the CSM that shows that the source of impacts is historical discharge and/or surface soil erosion from the upland LRIS.

4 INTERIM ACTIONS

The Port has conducted interim actions on the LRIS since 1996, with Ecology oversight and approval. The interim actions include the following:

- Initial source removal: included the initial actions to clean up the LRIS after PWT vacated the property.
- Emergency action: includes the SER system, which focused on removing mobile product related to the former tank farm and retort area.
- Current interim actions: include actions completed in Cells 1, 2, 3, and 4, based on Ecology-approved LRIS FSs and work plans.

Figure 4-1 shows interim actions completed on the LRIS, and Figure 4-2 shows the preferred alternatives for Cells 1 and 2 identified in the draft Cells 1 and 2 RI/FS (MFA, 2011a), which were implemented as an interim action in the spring, summer, and fall of 2012 and which will be finalized during the summer of 2013.

4.1 Initial Source Removal

Remedial actions were conducted from 1996 until 2002 as emergency and interim actions to meet requirements of the Order. The actions were focused on removing PWT equipment, tanks, and product; general site maintenance; and hot spot removal. The interim actions are detailed in the 2004 RI work plans (MFA, 2004, Vols. I, II, and III) and are summarized below for Cells 1, 2, 3, and 4.

4.1.1 Cells 1 and 2

- Replacement of the stormwater line and removal of drain tile and impacted soil west of the concrete pond to OF-3.
- Cleanout of the remaining stormwater system and installation and maintenance of catch basin and trench drain filters. The first cleanout was conducted in phases, starting in 1995 and ending in 1998. A second stormwater cleanout was conducted in 1999.
- Removal of the tank farm, retorts, PWT's WWTP, treated lumber, ancillary equipment, treating buildings, hazardous chemicals and sludge, the concrete pond, and the historical French drain system.
- Excavation of contaminated soil at the dry PCP spill area; soil where the City expanded its WWTP around sample locations T-4 and T-5; and soil near Building 6, around sample locations B-228, DS-N, and DS-S.

4.1.2 Cell 3

- Removal of treated wood left by PWT.
- Removal of an oil/water separator that historically discharged to OF-1.
- Removal of the drip trough and treatment of 300 cubic yards (CY) of impacted soils with peroxide. The soil was placed back in the excavation after treatment.
- Soil exceeding Method C CULs, centered on B-208 and B-220 in the western portion of Cell 3, was removed and placed in Cell 1.

4.1.3 Cell 4

A soil berm was constructed to direct surface water flow to Cell 2 and OF-3.

4.2 Emergency SER System

The SER system was constructed as an interim/emergency action to remove NAPL from the subsurface and prevent a free-phase product plume from migrating onto the RNWR from a portion of the LRIS (i.e., the SER area). The SER area and wellfield are shown on Figure 4-3 (note that the locations of the extraction wells [with an E- prefix] are also shown in Figure 4-3). The details of the SER system operation are provided in the draft Cells 1 and 2 RI/FS (MFA, 2011a) and the memorandum regarding discontinuation of steam injection (MFA, 2011d). The operations and performance of the SER system are briefly summarized below.

The SER system was constructed as an interim/emergency action, starting in 2002. The SER project was conducted in two phases, with a final polish stage.

Section 4 of the draft Cells 1 and 2 RI/FS (MFA, 2011a) discusses the 2004 to 2005 Phase 1 operations and the 2006 through 2010 Phase 2 operations in detail. A polish phase was conducted in 2011, and the SER system was shut down on June 30, 2011 (MFA, 2011d).

Phase 1 was a pilot study conducted through the center of the NAPL plume to evaluate the effectiveness of the system and obtain information to design the full-scale operation. Phase 2, the full-scale operation, was designed to thoroughly remediate the entire SER area. The polish stage treated the entire SER area at once from outside in and confirmed diminishing returns.

The SER process is based on steam flooding processes that have been used successfully in oil fields around the world. Steam is injected into the subsurface through a series of injection wells. As the heat is injected, semivolatile contaminants become volatile and are captured by vapor extraction wells; simultaneously, the viscosity of NAPL is lowered to allow recovery through groundwater extraction wells. Under an NPDES permit, treated water was discharged to Lake River through OF-3.

The SER system removed approximately 24,800 gallons of NAPL, disposed of over 500 tons of contaminated sludge, and treated over one million gallons of groundwater.

Based on performance of the system in Phases 1 and 2 and the lack of NAPL removal in the polishing phase, it was determined that the SER system had reached a point of diminishing returns. By the time the steam injection was discontinued on June 30, 2011, the approximately 4-acre NAPL footprint had decreased by 92 percent (MFA, 2011d).

Figure 4-4 shows the reduction of extent of NAPL through Phase 2. Note that before SER operation, NAPL thickness was up to approximately 3 feet; however, measurements at the end of Phase 2 found NAPL thickness approximately 0.1 foot or less.

After June 30, 2011, when steam injection was stopped, groundwater and vapor extraction continued during a cooldown period instituted to allow subsurface heat to decrease. Shutdown of vapor and groundwater extraction during the cooldown period was completed with Ecology approval on October 24, 2011 (Ecology, 2011d), followed by soil and groundwater sampling (see Sections 3.2.1.2 and 4.2.1). Decommissioning of the SER system, consistent with the closure plan (Port and Ecology, 2012), began during the summer of 2011.

4.2.1 SER Groundwater Evaluation

The SER was an emergency interim action designed to remove mobile contaminants (e.g., VOCs and some SVOCs). To evaluate performance, groundwater was regularly sampled from a number of the extraction wells during the operation of the SER system. In November 2011, MFA conducted the last of the groundwater sampling events to evaluate the SER area after SER treatment was complete. The sampling was conducted consistent with the Ecology-approved sampling work plan (MFA, 2011f). The analytical results for all of the SER groundwater monitoring events are summarized in Tables J-1-1 through J-1-4 in Appendix J.

The SER groundwater influent was also sampled regularly at a sample port identified as L0. Data from L0 represent an average concentration of chemicals as they are extracted from the subsurface. Figures 4-5 through 4-8 show the trend of analytical results from sampling port L0. The most prevalent and toxic wood-treating chemicals (i.e., PCP, naphthalene, benzene, and PCE) are shown on the figures. Note that during the startup of the SER system, concentrations of most chemicals were relatively high and some of the VOC analytes (e.g., benzene and PCE) had elevated MRLs because of interference by those analytes that were present at relatively high concentrations (e.g., naphthalene). Figures 4-5 through 4-8 show relatively high initial concentrations that decreased as SER operations continued. Spikes in concentrations typically occurred when operations began in a new treatment area.

Figures 4-9 through 4-18 compare the nature and extent of wood-treating chemicals in 2002, before the SER was initiated, with the nature and extent in November 2011. The November 2011 SER groundwater results show that concentrations of IHSs in groundwater are generally consistent with or lower than in previous sampling events. The most prevalent and toxic wood-treating chemicals (i.e., arsenic, benzene, naphthalene, PCE, and PCP) were modeled using EVS as described in Section 3.

Figures 4-9 and 4-10 show the extent of benzene in groundwater. In 2002, benzene was present throughout the SER area and extended beneath the RNWR in the UWBZ and LWBZ. Benzene historically was detected at up to 59 μg/L, but since August 2010, benzene generally has not been detected above the MTCA Method B CUL of 0.8 μg/L in the UWBZ or LWBZ in the SER area (see Table J-1-1 in Appendix J). Concentrations downgradient of the SER area have also been reduced, for example in the concrete pond area in the deep UWBZ and LWBZ (see Table 3-8). Also, benzene is no longer detected in monitoring wells in the RNWR north of Cell 2.

Figures 4-11 and 4-12 show the extent of PCE in groundwater. The concentration of PCE has been reduced, especially in the SER area. PCE historically was detected at up to approximately 58 μg/L; however, concentrations are still present above the Method B CUL of 0.081 μg/L[3] in some areas of the SER (see Table J-1-1 in Appendix J). Outside the SER area, PCE generally is detected only in LWBZ wells. PCE concentrations in the LWBZ beneath the SER area have decreased, while concentrations downgradient of the SER have been more stable (see Table 3-8). The source of the PCE in the former tank farm area appears to have been largely removed and concentrations are typically lower than those downgradient.

Figures 4-13 and 4-14 show the extent of naphthalene in groundwater. In 2002, naphthalene extended into the RNWR; the highest concentrations were in the former tank farm area and the former concrete pond area. Historically, naphthalene has been detected at up to 26,000 μg/L, but currently most of the naphthalene in the SER area is below the Method B CUL of 160 μg/L in the SER area (see Table J-1-1 in Appendix J). Also in 2002, naphthalene was present throughout the UWBZ, but is currently limited generally to the shallow UWBZ near other potential sources (i.e., the former concrete pond and the OF-2 stormwater catchment).

Figures 4-15 and 4-16 show the extent of PCP in groundwater. The concentration of PCP has been reduced, especially in the SER area. In past sampling events, PCP has been detected at up to 32,200 μg/L (see Table J-1-3 in Appendix J). Concentrations of PCP have been greatly reduced but PCP is still present above the Method B CUL of 0.73 μg/L in the SER area. Outside the SER area and the former concrete pond area, PCP generally is detected only in deep UWBZ and LWBZ wells (see Table 3-9). The source of the PCP in the former tank farm area appears to have been largely removed.

Figures 4-17 and 4-18 show the extent of arsenic in groundwater. Arsenic concentrations did not change much during the operation of the SER system, as shown by the figures. Concentrations decreased slightly in the western portion of the SER, while concentrations increased slightly in the eastern portion (although current concentrations are lower than detections from past sampling events in which arsenic was detected at concentrations as high as 530 μg/L) (see Table J-1-2 in Appendix J).

Figures 4-4 through 4-18 show that the SER has reduced concentrations of IHSs in groundwater and reduced the risk to downgradient receptors. The reduction in concentrations in the SER area has also created reduction of IHSs outside the SER area—most notably, concentrations in wells completed adjacent to or beneath the southern portion of Carty Lake in the RNWR. For example, USDFW-1, completed approximately 50 feet north of Cell 2 in the RNWR, historically detected

---

[3] Note that the Method B CUL for PCE was updated in 2012 to 5 μg /L.

benzene, carbazole, DROs, naphthalene, PCE, PCP, RROs, TCE, and vinyl chloride above MTCA CULs; however, in recent sampling events these compounds were not detected above CULs.

The November 2011 analytical results show that overall concentrations of IHSs have declined or remained stable since the last sampling event in December 2010. The overall results are similar to those reported in the SER discontinuation letter (MFA, 2011d) and shown in Figures 4-9 through 4-18. Some locations did have slight increases of a few compounds, with the most increases occurring at extraction well DEW-4, where six compounds have increased in concentration since December 2010.

4.3 Cells 3 and 4 Interim Action

Interim actions for Cells 3 and 4 were conducted during 2010 and 2011 and followed the May 27, 2010, Ecology-approved interim action work plan (MFA, 2010c). The work was conducted consistent with the requirements of the Order and the interim action requirements provided in WAC 1733-340-430. After the interim actions have been concluded, the details of the work will be provided to Ecology in a forthcoming interim action completion report. The actions conducted for each cell are described below.

4.3.1 Cell 3

Soil characterization samples collected throughout Cell 3 generally contained IHS results exceeding MTCA Method B soil CULs and/or ecological screening criteria.

In order to address the risk posed by exposure to the soil, capping and the excavation of hot spot soils (i.e., soils with concentrations above Method C soil CULs) was determined to be the preferred remedial alternative.

In Cell 3, the following locations had confirmed detections of IHSs that exceeded Method C CULs and required excavation (see Figure 4-1):

- MW-9S: arsenic and cPAH TEQ at 0.5 foot bgs
- SPY-01A: cPAH TEQ at 1 foot bgs
- SPY-01B: arsenic at 5 feet bgs
- SS-7: arsenic and dioxin TEQ at 0.3 foot bgs

Table 4-1 shows the approximate volumes of soil removed from the hot spot locations. Soil was disposed of at the Clean Harbors Aragonite Incineration Facility in Utah as hazardous waste.

After completion of hot spot excavation, Cell 3 was graded in preparation for the clean soil cap. This included regrading the Lake River bank and removing a bulkhead and barge-loading ramp.

Soil for the soil cap was from the Interstate 5 interchange construction project. Before placement on site, the soil was analyzed consistent with the Ecology-approved soil acceptance plan (MFA, 2007), and the results were presented to Ecology in a letter report (MFA, 2007). The soil did not contain site IHSs above Method B CULs or natural background concentrations.

Obstructions on Cell 3 (e.g., building, loading ramps, and pilings) were removed before installation of the soil cap. Activities included the removal of the UPRR spur railroad line and a groundwater monitoring well (i.e., MW-28S). Concrete was crushed and surface applied before cap placement. In addition, stormwater improvements on Cell 3 included decommissioning of stormwater outfall OF-1 and replacement with two new outfalls, OF-5 and OF-6. Stormwater improvements were implemented before cap installation.

A geotextile (SKAPS GT-160 Nonwoven Geotextile™ or equivalent) was placed on a smooth, prepared surface, free of puncture obstructions, between the contaminated surface and the clean fill. The geotextile was used as a demarcation layer between the impacted site soils and the soil cap.

A minimum of 2 feet of soil was placed over the geotextile and compacted. The cap was deeper in certain areas to allow for additional, stabilizing vegetation (e.g., the bank along Lake River in Cell 3) and to contour the cap to control stormwater. In addition, capping was elevated in the upland area in order to protect the cap from potential flooding (as the cap is partially located within the 100-year floodplain) and in preparation for development. The capping will be inspected and maintained consistent with a soil management plan (SMP) and a cap maintenance plan.

4.3.2 Cell 4

Soil characterization samples collected throughout Cell 4 contained IHS results exceeding MTCA Method B soil CULs and/or ecological screening criteria. As the risk posed by exposure to the soil is best addressed by capping and excavation of soils exceeding Method C soil CULs, these were determined to be the preferred remedial alternative action.

In Cell 4, the following locations had confirmed detections of IHSs that exceeded Method C CULs, and therefore the soil was removed as part of the interim action (see Figure 4-1):

- SS-4B detected dioxin TEQ at 0.3 foot bgs.
- SS-30 detected dioxin TEQ at 0.5 foot bgs.

Table 4-1 shows the approximate volumes of soil removed from the hot spot locations. Soil was disposed of at the Clean Harbors Aragonite Incineration Facility in Utah as hazardous waste.

Stormwater improvements were implemented before cap installation. A pipe and catch basins were installed to direct stormwater to Cell 2 and eventually to outfall OF-3. A geotextile (SKAPS GT-160 Nonwoven Geotextile™ or equivalent) was placed on a smooth, prepared surface, free of puncture obstructions, between the contaminated surface and the clean fill. The geotextile was used as a demarcation layer between the impacted site soils and the soil cap.

A minimum of 2 feet of soil was placed over the geotextile and compacted. The cap was deeper in certain areas in order to contour the cap to control stormwater. The capping will be inspected and maintained consistent with an SMP and a cap maintenance plan.

4.4 Cells 1 and 2 Interim Action

The Cells 1 and 2 interim action is currently under way and is to be completed by summer 2013. The interim action includes removal of historical PWT structures and impacted soils, grading and capping, institutional controls, and completion of the SER, including the polishing phase. The work is being completed consistent with the April 13, 2011, Ecology-approved interim action work plan (MFA, 2011b). The work will be conducted consistent with the requirements of the Order and the interim action requirements provided in MTCA WAC 173-340-430. The interim action is based on the preferred alternative in the draft Cells 1 and 2 RI/FS (MFA, 2011a). Figure 4-2 shows the interim action locations for Cells 1 and 2. After the interim actions have been concluded, the details of the work will be provided to Ecology in a forthcoming interim action completion report. The Cells 1 and 2 interim action began during the summer of 2012 and will be completed by summer 2013. Below is a summary of actions associated with the Cells 1 and 2 interim action.

4.4.1 Historical Feature Removal, Grading, and Capping

As described in Section 3, IHSs generally extended over the entire LRIS. As the risk posed by exposure to the soil is best addressed by capping, this was determined to be the primary preferred alternative action (MFA, 2011a). Soil capping is also protective of potential ecological receptors.

Obstructions (e.g., buildings, surface completions, pilings) were removed before grading and placement of the soil cap. Grading will include regrading the Lake River bank along Cell 2. Actions required to address existing site features included the following:

- Demolition of site buildings
- Crushing of concrete pads, rubble, and foundation, and removing or grading them into the LRIS
- Removal of site rail lines and existing stormwater piping and trenching
- Installing a new stormwater system

4.4.2 Soil Removal

4.4.2.1 Concrete Pond

As stated in Section 3.2.1.1, Cell 2 contained an area of NAPL around the former location of the concrete pond that had been removed as part of the interim action, also identified as the "concrete pond excavation." Until the early 1970s, the concrete pond was used to treat wastewater generated by site operations. NAPL identified around the former location of the concrete pond originated from this feature. The observed NAPL and associated soils were removed during the 2012 interim action work.

The concrete pond excavation began in mid-June and continued through mid-July 2012. Impacted soil excavated from the concrete pond contained listed hazardous waste at levels above Method C CULs and was considered and handled as a listed hazardous waste being transported directly to

Waste Management's Subtitle C Hazardous Waste Landfill in Arlington, Oregon. The final extent of the concrete pond excavation was determined by visual inspection for the presence of NAPL. Soil was excavated using conventional excavation equipment (e.g., backhoe). Approximately 5,700 CY of impacted soil was removed from the concrete pond excavation and disposed of at the Arlington Landfill.

The depth of the excavation associated with the concrete pond averaged 15 feet bgs. Because the concrete pond releases occurred below the ground surface, approximately 4,700 CY of clean overburden that did not have NAPL impacts was removed and stockpiled for use as backfill after completion of the excavation.

Groundwater was encountered in the concrete pond excavation between 6 and 13 feet bgs. The excavation was dewatered and the liquid collected into baker tanks and treated before disposal.

Details of the concrete pond excavation will be provided to Ecology in a forthcoming interim action completion report.

4.4.2.2 Hot Spot Soil

The preferred alternative for Cells 1 and 2 includes removal of soil above MTCA Method C CULs in areas outside the SER treatment area (MFA, 2011a). The following locations (hot spot areas) are located outside the SER treatment area and have confirmed detections of IHSs in soil that exceed Method C CULs; these were excavated and removed from the Site in 2012:

- B-308: dioxin TEQ at 15 feet bgs (included in former concrete pond excavation, discussed above)
- MFP-01: PCP at 3.0 feet bgs (included in former concrete pond excavation, discussed above)
- SS-14: dioxin TEQ at 0.5 foot bgs
- TP-03: PCP at 0.3 foot bgs
- TP-13: arsenic at 0.2 foot bgs (included in former concrete pond excavation, discussed above)

Locations SS-14 and TP-03 were separate excavations, unrelated to the concrete pond. These were excavated to approximately 1 foot bgs, with a combined volume of approximately 19 CY.

In addition, 25 CY of soil was removed near the stormwater catchment to address what may have been the source of elevated groundwater concentrations in the area (MW-57S). Final excavation extents were determined through confirmation sampling of the sidewalls and bottoms of the excavations. Excavated soil from the hot spot areas was direct-loaded for disposal at the Arlington Subtitle C landfill. Details of the hot spot excavations will be provided to Ecology in a forthcoming interim action completion report.

4.4.3 Institutional controls

Institutional controls for Cells 1 and 2 include restrictions for soil and groundwater and construction requirements related to the cap. The institutional controls will be detailed in a forthcoming cleanup action plan.

As described in Section 4.2, the more mobile contaminants have been reduced in the SER soils; however, limited impacts of less mobile compounds such as metals and dioxins remain at elevated concentrations. Since the more mobile contaminants were removed, capping and institutional controls in Cell 1 have been determined to be effective in protecting human health and the environment. The following locations in Cell 1, in the SER area, have confirmed detections in soil of IHSs that exceed Method C CULs:

- B-317 for arsenic (140 mg/kg) at 1.25 feet bgs
- B-322 for arsenic (241 mg/kg) and dioxin TEQ (8,100 ng/kg) at 2.5 feet bgs

4.4.4 SER System

Actions associated with the SER system, including the polish phase, are summarized in Section 4.2.

Polishing was completed on June 30, 2011.

5 CONCEPTUAL SITE MODEL

The CSM describes the physical and chemical conditions on the LRIS, the upland off-property (Port-owned properties and non-Port-owned properties), Lake River offshore of the LRIS, and Carty Lake. The CSM identifies potential chemical sources, release mechanisms, environmental transport processes, and potential exposure pathways and receptors (WAC 173-34-200). The primary purpose of the CSM is to identify contaminant sources and migration, to describe pathways by which human and ecological receptors may be exposed to site-related chemicals in the environment, and for planning effective cleanup and eliminating sources of potential recontamination. According to the USEPA (1989), a complete exposure pathway consists of four necessary elements: (1) a source and mechanism of chemical release to the environment; (2) an environmental transport medium for a released chemical; (3) a point of potential contact with the impacted medium (referred to as the exposure point); and (4) an exposure route (e.g., incidental sediment ingestion) at the exposure point.

Potential source areas and chemical release and transport mechanisms that can allow chemicals to migrate to potential receptors are summarized for the Site. In addition, a discussion of significant exposure points, pathways, and potential receptors for each area (i.e., LRIS, upland off-property, Lake River, and Carty Lake) is presented separately in individual sections. The human health and ecological CSM depicting exposure pathways and potential receptors is shown in Figure 5-1.

5.1 Sources

Suspected historical sources of soil, groundwater, and/or sediment impacts at the LRIS include wood-treating chemicals and other substances that were used as part of wood-treating operations. Historical LRIS features are shown on Figure 2-1; potential historical sources include:

- Spills in the process areas in Cells 1 and 2 (i.e., tank farm, retorts, drip pad) that impacted LRIS surface and subsurface soil and groundwater.
- Releases to surface soil in Cells 1, 2, and 3 such as incidental drips of chemicals from treated wood.
- Releases to surface and subsurface soil during operation of the former drip trough in Cell 3. These releases also appear to have impacted groundwater.
- Releases in Cell 3 (where treated wood was stored) from drippage and "washing" by precipitation-impacted surface soil.
- Washing of treated wood via precipitation and subsequent soil impacts or stormwater discharge to Lake River and/or Carty Lake.
- Discharge of the concrete pond contents to stormwater outfall OF-3 on Lake River. The concrete pond was used until the early 1970s to treat wastewater generated by site operations. NAPL and other soil and groundwater impacts identified around the former concrete pond originated from this feature.
- Stormwater catchment (similar to the concrete pond) near the western edge of former Building No. 8 and MW-57S discharged stormwater to OF-2. Soil and groundwater impacts were identified around this feature.
- Historical LRIS activities leading to dioxin formation; proximate source(s) are not well established.
- Overwater activities, such as barge loading adjacent to Cell 3.

In addition to former PWT-related sources, background sources of chemicals represent a ubiquitous input to the Site. WWTPs are a common source of low-level chemical impacts. The City's WWTP is located north of Cell 1 (see Figure 4-1). The effluent from the WWTP is piped underground along the northern portion of Cell 2 and discharges into Lake River at the northern boundary of Cell 2. Historically, the line discharged from a pipe located at the bank. During the summer of 2006, the City upgraded its outfall and added a diffuser in Lake River. The WWTP outfall upgrade was performed under the direction of Ecology and includes ongoing discharge monitoring as outlined in the associated NPDES permit.

Dioxins are widespread in the environment and can result from both natural and anthropogenic sources (USEPA, 2006). The area around the LRIS is an urban environment where industrial activity has been conducted and a city has been established for over 100 years. In urban areas, dioxins can result from vehicle emissions, back-yard trash burning, structure fires, stormwater runoff, and other common events and activities. Therefore, low levels of dioxins are present in soil or sediment because of natural and/or non-point anthropogenic activities.

It is likely that low levels of dioxins resulting from background sources are also present in Lower Columbia River sediment (see Appendix K) and that they similarly impact Lake River and Carty Lake sediment, since atmospheric deposition is a primary dioxin transport mechanism.

5.2 Transport

Potential contaminant transport mechanisms operating at the Site include direct discharge to soils, tracking of soil impacts by vehicles, leaching of chemicals in soil to groundwater, groundwater flow to surface water, outfall discharge to sediments, stormwater runoff to soils and/or sediments, soil erosion, atmospheric deposition to soils and/or sediments, chemicals in soil/groundwater volatilizing to air, sediment erosion caused by waves, erosion of soils and/or sediment caused by propeller wash, water current sediment erosion, groundwater infiltration, and food chain transfer originating from impacted media.

In sediments, physical transport of contaminants can be upward (advection/diffusion, ebullition), downward (advection/diffusion, burial), or lateral (resuspension/deposition); bioturbation caused by benthic organisms can further displace or mix contaminants. In water, contaminants can move by the same advective and diffusive forces operating in the sediment, by sorption to/from sediments resuspended by currents or scour events, or via bioturbation (e.g., releases from sediment to the water column).

The relative importance of the above processes will vary, depending on the chemical and physical properties of a released contaminant. The properties of soil and the dynamics of groundwater flow also shape contaminant fate and transport. The most significant site-specific transport mechanisms are discussed further below.

5.2.1 Stormwater Transport

As discussed in Section 3.5.2.1, magnitude and extent of dioxins in Lake River are consistent with localized historical stormwater impacts to sediment adjacent to outfalls and along the nearshore areas of Lake River. These results support a conceptual model for historical stormwater impacts, with the Lake River area farther offshore of stormwater outfalls showing low-level dioxin concentrations. Thus historical stormwater inputs from LRIS outfalls and/or surface soil erosion from upland areas likely are contributing sources of contamination observed in nearshore Lake River sediment adjacent to the LRIS.

As part of LRIS interim actions, the stormwater system was removed and a new system was installed (see Section 4). The new system was intentionally routed around areas of previously known contamination (such as the concrete pond), and no visible impacts were observed in the pipe trenches during excavation. Further, because the new stormwater system was installed above the groundwater level, the system is not going to act as a preferential pathway for contaminated groundwater.

Slightly elevated contamination found at LRIS-LR-16, south of the LRIS, likely is related to the City stormwater outfall located approximately 900 feet south of the LRIS (see Figure 3-15). The drainage basin for this outfall had not been determined by the City, but MFA was able to model it using City stormwater maps and direct observation (see Appendix L). Catchment areas in the City-determined stormwater outfall drainage area were calculated by using a combination of Civil3D and ArcGIS Spatial Analysis tools, as well as surface topography. These computer-generated catchment areas were based on the information available and on a site visit, and are further described in Appendix L. MFA concluded that the contamination at LRIS-LR-16 is unrelated to the Site. This conclusion and the supporting information were presented to Ecology on February 10, 2012, and are included as Appendix L. The Port received an e-mail on February 24, 2012, in which Ecology concurred with this conclusion.

5.2.2 Sediment and Shoreline Processes

A number of processes, including water flow, wave erosion, and propeller wash, have the potential to impact sediment transport in Lake River and/or Carty Lake.

High-percent fines coupled with low water velocities (see Section 2.7.1) indicate that Lake River is a low-energy depositional environment. Therefore, contaminant resuspension and redistribution due to bed-shear caused by river currents is not expected to be a significant mechanism for transport, as evidenced by significantly reduced or non-detect chemical concentrations both upstream and downstream of the Site. Evidence for significant sediment accumulation in Lake River near the Site (see Section 2.7.1) also indicates potential for long-term improvement of chemical concentrations in surface sediment via natural recovery (i.e., deposition) processes.

Wind waves are not anticipated to be a mechanism for erosion in Lake River. The limited straight line fetch distance (an area in which waves are generated by wind) in Lake River, combined with the shallow depths of the river (approximately 7 to 8 feet), limits wind wave production in Lake River. Wakes from passing vessels will be much larger and are a potential factor for sediment movement. Wakes likely range from 1 foot (for a 25-foot recreational vessel traveling at 8 miles per hour) to 2.5 feet (for a 35-foot sport yacht). Erosion potential along the shoreline due to wakes is expected from approximately 4 feet below low water in Lake River (1.5 times the wave height) up to mean higher high water (Anchor and MFA, 2011).

Portions of Lake River are potentially vulnerable to erosion from propeller wash. Wakes from passing recreational vessels have the potential to resuspend fine materials in water depths of less than 8 feet; except for the centerline of the navigation channel, Lake River is generally less than 8 feet deep. The center of the channel may also be within 8 feet of water depth during low-flow periods in the Columbia River. Areas near the public boat launch just upstream of the LRIS will be exposed to higher-velocity propeller wash because of launching and berthing activities in that area. Areas (regardless of depth) in the vicinity of the boat launch and attached dock likely will be subject to bed erosion (Anchor and MFA, 2011).

Sediment resuspension and transport potential is low in Carty Lake. High-percent fines and organic carbon, absence of a water inlet/outlet except during flood events, and lack of propeller wash (boats are not allowed on Carty Lake) all evidence Carty Lake as a low-energy depositional environment (see Section 2.7.2). Its small size, shallow depths (approximately 3 to 10 feet), and lack of boat use also likely limit wave production. The absence of steep side slopes minimizes potential for shoreline erosion.

The following summarizes the general sediment transport potential:

- Lake River currents are not anticipated to resuspend materials from the river bottom.
- Wind waves are not anticipated to resuspend materials from the river bottom or erode side slopes in Lake River.
- Propeller wash from passing vessels has the potential to resuspend material from portions of the bed in Lake River (areas with less than 8 feet of water depth).
- If material is resuspended from the bed of Lake River, fine sediments with low fall velocity (silts and clays) could be transported.
- Wakes will range from about 1 foot to 2.5 feet in Lake River. These waves can induce erosion of side slopes on either side of Lake River for most of its navigable length down to approximately 4 feet below low water.
- Sediment transport potential is low in Carty Lake.

5.2.3 Groundwater Fate and Transport Modeling

The potential for groundwater to discharge to Lake River or Carty Lake and adversely impact surface water is evaluated. Groundwater in the shallow portion of the UWBZ likely discharges to Lake River; however, the deep UWBZ and the LWBZ do not discharge to Lake River (see Section 2.5). Further, based on lithology, hydrogeology, and head potential, it is also unlikely that the UWBZ or LWBZ discharges to Carty Lake (see Section 2.5). The head difference between Carty Lake and the UWBZ indicates that the groundwater flow potential is downward, although a confining layer between them likely restricts water movement. However, as a conservative measure, IHSs in groundwater near the water bodies in the shallow and deep UWBZ were modeled to evaluate the potential for adverse impacts to occur if groundwater were to discharge to surface water. The most downgradient wells with the highest concentrations of IHSs for each of the two plumes were modeled (i.e., MW-4, MW-10, MW-55S, MW-55D, MW-58D, RMW-2S, RMW-2D, USDFW-1, USDFW-2, and USDFW-3 [Cells 1 and 2 plume], and MW-45D, MW-46S, and MW-47D [Cell 3 plume]).

In order to determine the appropriate IHSs to model, groundwater results from monitoring wells installed nearest the water bodies were compared to MTCA Method B surface water CULs (Ecology, 2011e) and the USEPA national recommended WQC for freshwater CCC for aquatic organisms, for HH consumption of organisms only, and for HH consumption of organisms and water (MFA, 2007, 2011; USEPA, 2009). The chemicals that exceed the surface water criteria in one or more samples were modeled. These included:

- Lake River—Cells 1 and 2 Plume
  - Metals: arsenic and chromium
  - SVOCs: BEHP, dibenzofuran, PCP
  - VOCs: benzene and PCE
- Lake River—Cell 3 Plume
  - Metal: arsenic
  - SVOCs: PCP
  - VOC: PCE
- Carty Lake—Cells 1 and 2 Plume
  - Metals: arsenic and chromium
  - SVOCs: BEHP and PCP

The modeling was performed using the USEPA's BIOCHLOR model. Detailed descriptions of the model, the model inputs, and assumptions are included in the RIs (MFA, 2007, 2011a). General assumptions are outlined below:

- Site-specific hydraulic conductivities (Ks) were calculated using slug test results from Cells 2 and 3, and organic carbon data were collected from the sediment investigations in Lake River and Carty Lake. The default conservative fraction organic carbon (FOC) of 0.0018 was used for soil in the aquifer.
- To account for differences in FOC and Ks between the WBZs, groundwater modeling was conducted in two phases for contaminants present in the deep UWBZ. First, groundwater was modeled from the monitoring well to the riverbank, using the default FOC and the deep UWBZ Ks, and the modeled concentrations at the riverbank were then input into the second model as starting concentrations. The second model used the site-specific FOCs and the shallow UWBZ Ks to model groundwater to the assumed discharge point.
- It was assumed that the shallow and deep areas of the UWBZ discharge by the river's midpoint and that hydrologic conditions in Cells 2 and 3 are mirrored on the RNWR River "S" unit side of Lake River. Discharge concentrations were, therefore, estimated at the midpoint between the riverbank and the middle of Lake River.
- For purposes of modeling groundwater, it was assumed that the entire portion of the UWBZ discharges to Carty Lake by 50 feet from the typical dry season lake boundary (see Figure 2-1).
- An average concentration of chemicals, except for chromium, from the well with the highest detections was used in the modeling. The maximum chromium detections were

used in the modeling because only a few detections have exceeded the hexavalent chromium screening values.[4]

- A constant, nondegrading source was assumed.
- The models assumed a 30-year time frame. Given that the primary source of the contamination (i.e., the SER area) is no longer present, it is unlikely that impacts will continue for this length of time.

The model predicts for each plume that BEHP, benzene, dibenzofuran, PCP, and/or PCE are naturally attenuated to concentrations below analytical MRLs; that chromium is reduced below regulatory screening levels for hexavalent chromium in groundwater and surface water; and that arsenic is reduced to concentrations below the natural background concentration for Washington State (0.005 milligram per liter) before reaching Lake River or Carty Lake. Modeling results and parameters are included in Table 5-1.

Groundwater sampling and analysis conducted across Lake River from the LRIS in the RNWR indicate that IHSs found in Cells 1, 2, and 3 are not present in the RNWR at detectable concentrations (MFA, 2007). Based on the modeling results and the groundwater sampling data from west of Lake River, IHSs in groundwater at the estimated groundwater-discharge boundary with Lake River and Carty Lake are below MRLs and/or reduce to below regulatory surface water screening levels or natural background concentrations. Therefore, groundwater discharge to surface water is not considered a complete transport pathway.

Note that naphthalene was not modeled because, when modeling was completed, naphthalene was not present in reconnaissance groundwater samples that had been collected directly downgradient of MW-57S. After modeling was completed, naphthalene was detected at concentrations above the Method B CUL in newly installed monitoring well MW-55S, located approximately 180 feet downgradient of MW-57S. MW-55S is approximately 70 feet from the bank of Lake River. Naphthalene concentrations decrease from MW-57S to MW-55S by approximately 90 percent. For example, the naphthalene concentrations from August 2011 were 18,700 μg/L (MW-57S) and 938 μg/L (MW-55S). The decrease in concentrations indicates that naphthalene decreases significantly (e.g., up to approximately 100 μg/L per foot) near the riverbank and will not reach Lake River at detectable concentrations.

5.3 LRIS Exposure Scenarios

Potentially complete exposure pathways for LRIS soil, groundwater, and surface water adjacent to the LRIS are described below.

---

[4] Non-speciated chromium screening levels are not available.

5.3.1 Potentially Complete Soil Exposure Pathways

The LRIS was formerly an industrial site that was first used for industrial purposes in the early 1900s. Public use and access to the Cells are restricted until the interim actions are completed. The Port staff occupy the one building that remains on site.

The LRIS is zoned by the City for waterfront mixed use. Under this classification, allowed uses include ground floor commercial with upper story living units; retail, restaurants and lodging; and service industries, among other types of commercial use. Therefore, it is possible that commercial workers will occupy the LRIS at some time in the foreseeable future.

Scenarios by which human receptors may contact wood-treating chemicals in soil include the following:

On-site commercial workers—Commercial workers currently occupy the LRIS and are likely to do so in the future. It is assumed that future workers could contact chemicals in the top 15 feet of the current ground surface.

The pathways by which future workers could potentially be exposed to wood-treating chemicals in soil include direct skin contact with soil, incidental ingestion of soil, and inhalation of soil particulates. There is potential for inhalation of volatile compounds in soil that have migrated to indoor air in Cells 1 and 2; however, in Cells 3 and 4, VOCs generally were not detected in soil samples, and therefore exposure to VOCs from soil is not considered a significant exposure pathway.

On-site construction workers—There are currently no construction workers (e.g., excavation workers, trench workers) working on the LRIS. However, construction activities likely will be performed as part of site redevelopment and remediation. Construction workers could contact IHSs in soil at 0 to 15 feet bgs through incidental ingestion, dermal contact, and inhalation of impacted soil particulates.

The 100-year floodplain elevation is approximately 26.5 feet NGVD and groundwater is typically below 11 feet bgs. Therefore, once the fill has been placed on site to bring the ground surface above the 100-year floodplain elevation for development purposes, groundwater will typically be below 15 feet bgs, which is the maximum excavation depth of most excavating equipment without engineering controls. In addition, utilities are typically installed above the water table. It is unlikely that trench workers will come into contact with contaminated groundwater because excavations are unlikely to extend to the water table.

On-site recreational users—There are currently no recreational users in the LRIS. However, future development may include recreational uses. The pathways by which a future recreational user could potentially be exposed to IHSs in soil include incidental ingestion, dermal contact, and inhalation of soil particulates.

Terrestrial ecological receptors—As a result of past operations, the LRIS is disturbed and does not support natural habitats important for native plants and wildlife. Based on current land use plans, it is unlikely that the LRIS will be redeveloped as a natural area. Therefore, terrestrial ecological receptors are unlikely to have significant exposure to IHSs in soil.

However, the LRIS is adjacent to the RNWR, which is an important regional resource for a variety of wildlife. Because of the close proximity of the RNWR, a TEE has been conducted for the LRIS (MFA, 2010a). This TEE describes interim remedial actions, protective of potential future ecological receptors, that will be implemented on the LRIS (see Appendix B).

5.3.2 Potentially Complete Groundwater Exposure Pathways

As discussed in Section 3.3, groundwater in Cell 4 has not been impacted by contaminants. In addition, it is unlikely that contaminants will migrate to groundwater in the future (see the Cell 4 RI/FS [MFA, 2010e]). Human or ecological receptors that may contact either groundwater or surface water that has received groundwater discharge will not be exposed to contamination in Cell 4.

Groundwater impacts have been identified in Cells 1, 2, and 3. Potentially complete groundwater exposure pathways are discussed below for these Cells.

Drinking Water Pathway

Groundwater in the vicinity of the LRIS is not used for drinking. Drinking water is provided by the City (i.e., municipal water supply). There are no drinking-water wells at the LRIS or immediately downgradient of the LRIS.

The city draws drinking water from wells located approximately 3,000 feet (0.6 mile) upgradient of the LRIS, in Abrams Park. The City is currently conducting a hydraulic study to investigate expanding the current waterworks system (Wall, 2006). It appears that the City can construct one additional well at Abrams Park. The City plans to develop drinking water supplies near the I-5 junction once the Abrams Park well installation is complete. A test well has already been completed near the junction. If additional water needs arise, beyond the additional wells planned at Abrams Park and the I-5 junction, the City will install wells east of I-5. Mr. Steven Wall, PE, the City's public works director, stated that water wells will not be installed west of Abrams Park, in the direction of the LRIS.

Human receptors are unlikely to have direct exposure to IHSs in groundwater at the LRIS. Groundwater is not used for drinking, and it is unlikely that IHSs in groundwater will be transported to an aquifer that could be used for drinking. Given the availability, reliability, and relatively low cost of municipal water, it is unlikely that water-supply wells will be developed at or near the LRIS in the foreseeable future. The Port will ensure that groundwater will not be used in the future by placing a restrictive covenant on groundwater use for the entire LRIS.

Vapor Intrusion

In Cells 1 and 2, it is possible for human receptors to have indirect exposure to groundwater IHSs in excavation trenches or outdoor air. VOCs in groundwater may volatilize and migrate in soil gas into existing or future buildings.

Based on the available information, VOCs historically were not used in the Cell 3 area, although it appears that an off-site source has contaminated groundwater beneath Cell 3 with PCE. However, migration of PCE vapors from groundwater to either indoor or outdoor air is not considered to be a complete exposure pathway in Cell 3. PCE is detected almost exclusively in monitoring wells completed in the deep portion of the UWBZ. In order for PCE to enter the vapor phase and migrate to indoor or outdoor air, it would first have to migrate to the top of the water table through diffusion or advection (where it would be detected in groundwater samples). In samples collected from monitoring wells completed in the shallow portion of the UWBZ, PCE was detected in only one sample (from MW-45S). The detection occurred in the first sampling event conducted in the newly constructed monitoring well, and PCE was not detected at this location in subsequent groundwater-sampling events. It therefore appears that attenuation processes prevent PCE from migrating to the interface between groundwater and vadose-zone soils at detectable concentrations.

5.3.3 Potentially Complete Surface Water Exposure Pathways

Two surface water bodies are adjacent to the LRIS: Lake River and Carty Lake. Lake River and Carty Lake exposure scenarios are discussed in greater detail in Sections 5.5 and 5.6. As discussed above, there are no current complete pathways, via groundwater or stormwater overland flow, to the southern portion of Carty Lake. It is assumed that shallow groundwater discharges to Lake River. However, as discussed in the groundwater modeling in Section 5.2.3, concentrations of IHSs in surface water and sediment pore water near the groundwater-discharge boundary are estimated to be below MTCA B CULs, surface water criteria, and/or background concentrations (for modeling details see the Cells 1 and 2 RI/FS, Appendix H; and Section 5.1.3 in the Cell 3 RI [MFA, 2007, 2011a]).

Site stormwater currently drains to catch basins by overland flow and discharges directly into Lake River. The Port samples stormwater on a routine basis in a manner consistent with its NPDES permit. It is assumed that aquatic biota in both surface water and sediment could contact waterborne IHSs if impacted stormwater discharges to Lake River, and that recreational users of Lake River could contact IHSs in surface water. Potential exposure routes include incidental ingestion of surface water, dermal contact with surface water, and ingestion of fish that bioaccumulate IHSs from surface water or sediment. However, upland remedial actions (i.e., soil capping and stormwater conveyance system replacement) are completed or are under way to eliminate the potential transport of impacted stormwater to Lake River (see Sections 4 and 5.2).

5.4 Upland Off-Property Exposure Scenarios

The upland off-property area includes Port-owned properties and non-Port-owned properties. Currently, the Port-owned Railroad Avenue properties to the east of the LRIS consist of undeveloped land zoned waterfront mixed-use. The Port-owned parking and landscaped areas and the Port-owned proposed overpass property to the south of the LRIS are zoned waterfront mixed-use. The off-property area east of the LRIS is predominantly residential, while McCuddy's Marina is privately owned. The property north of the LRIS is RNWR-owned land. Figure 2-21 displays the zoning designations for all areas.

Wood-treatment chemicals associated with historical Port operations are not detected above CULs or levels consistent with background in upland off-property areas. Dioxins are identified as an IHS for the off-property areas (see Section 3.2.2.1).

The most elevated dioxin concentrations occur on the Port-owned properties (i.e., Railroad Avenue properties) zoned waterfront mixed-use (see Section 3.2.2.2). Dioxin characterization in non-Port-owned properties, including the residential area, has been conducted primarily in rights-of-way; other exposure points (e.g., yards) have not been characterized. Exposure scenarios are developed separately for Port-owned properties and non-Port-owned properties.

5.4.1 Port-owned Properties

The primary exposure pathways are identified for surface soils east and south of the LRIS. Potential exposure pathways and receptors include:

- Human direct contact, including incidental soil ingestion, dermal contact, or inhalation
- Human secondary ingestion (consumption of chemicals in produce)
- Ecological receptor direct contact, including soil ingestion/uptake, dermal contact, and inhalation
- Ecological receptor secondary ingestion (consumption of chemicals in plant material and/or prey by upper trophic level receptors)

Human Health CSM

Exposure scenarios are shown in Figure 5-1. Potential human receptors include workers (e.g., construction) and residents (adults and children). Note that exposures to residents on Port-owned properties may be significantly less than in residential areas because of less frequent use; however, this pathway is retained. Human incidental soil ingestion may occur. Paustenbach et al. (2006) found dermal contact with dioxins and the inhalation pathway for dioxins to be relatively insignificant exposure pathways relative to incidental soil ingestion. Based on these findings, human incidental ingestion of soil is the most significant potential exposure pathway.

Ecological Receptor CSM

Exposure scenarios are shown in Figure 5-1. Potential ecological receptors include wildlife (e.g., mammals and birds) and plants. However, the Port-owned properties provide minimal important ecological habitat because of substantial human disturbance and the lack of important resources for wildlife (see Figure 2-2). Wildlife may visit the area, but potential exposures of wildlife receptors to impacted soil are expected to be minimal, as their foraging range is unlikely to be restricted to these areas. Based on the upland off-property TEE, impacts in Port-owned area soils are not expected to result in unacceptable risk to ecological receptors, with the exception of dioxins in the Port Railroad Avenue properties (see Appendix B).

Summary

Human incidental ingestion of soil is identified as a potential exposure pathway, while unacceptable risk to ecological receptors is limited to exposure to the Port Avenue Railroad properties.

5.4.2 Non-Port-owned Properties

The primary exposure pathways are identified for surface soils east and south of the LRIS. Potential exposure pathways and receptors include:

- Human direct contact, including incidental soil ingestion, dermal contact, or inhalation
- Human secondary ingestion (consumption of chemicals in produce)
- Ecological receptor direct contact, including soil ingestion/uptake, dermal contact, or inhalation
- Ecological receptor secondary ingestion (consumption of chemicals in plant material and/or prey by upper trophic level receptors)

Human Health CSM

Exposure scenarios are shown in Figure 5-1. Potential human receptors include residents (adults and children) and workers (e.g., construction). Recent findings support limited potential exposure from dermal contact, inhalation, and produce-consumption pathways. Paustenbach et al. (2006) conducted a probabilistic risk analysis of cancer risks and noncancer hazards for exposures to adults and children (up to 6 years old) from dioxins in urban residential soils. The probabilistic risk analysis determined that the most sensitive determinants of dose and risk are childhood soil ingestion, exposure duration, and the selected TCDD cancer potency factor. Paustenbach et al. (2006) found dermal contact with dioxins in soil to be a relatively insignificant exposure pathway relative to incidental soil ingestion and stated that the inhalation pathway for dioxins in soil is insignificant relative to the direct-contact pathways. Paustenbach et al. (2006) also provided a discussion of the transfer of dioxins in soil to home-grown vegetables/plants and concluded that this exposure pathway was insignificant, given that:

- The extremely low vapor pressure of dioxins prevents any substantial vapor flux from contaminated (and often long-weathered) soils.
- The suspension of local soils with subsequent deposition on plants is expected to be nominal for dioxins because of normal washing, processing, and/or cooking of vegetables.

Based on these findings, human incidental ingestion of soil is the most significant potential exposure pathway.

Ecological Receptor CSM

Exposure scenarios are shown in Figure 5-1. Potential ecological receptors include wildlife (e.g., mammals and birds) and plants. However, the non-Port-owned properties do not provide important ecological habitat (except for the RNWR property) because of residential development, i.e., there is substantial human disturbance and there are no important resources for wildlife (see Figure 2-2). Wildlife may visit the area, but potential exposures of wildlife receptors to impacted soil are expected to be minimal, as their foraging range is unlikely to be restricted to this urban area. Based on the upland off-property TEE, impacts to soil are not expected to result in unacceptable risk to ecological receptors (see Appendix B).

Summary

Human incidental ingestion of soil is identified as a potential exposure pathway, although potential exposure points in residential areas (i.e., yards) have not been characterized. Unacceptable risk to ecological receptors is not expected.

5.5 Lake River Exposure Scenarios

Lake River offshore of the LRIS is a relatively shallow, slow-velocity river that is frequented by recreationists and is habitat to aquatic animals, including special-status salmonids, waterbirds such as the great blue heron, and aquatic mammals such as the river otter. Lake River's setting, fluvial dynamics, and uses are further described in Section 2.

Dioxins are identified as IHSs for Lake River sediment. See Section 3.5.2.1 for a discussion of IHS screening. Other contaminants at elevated concentrations are colocated with elevated dioxin concentrations, and any cleanup action directed at dioxins is expected to remedy those contaminants.

Potentially complete exposure pathways for human health and ecological receptors are described below and are presented in Figure 5-1.

Human Health CSM

The principal human receptors that have the potential to contact sediment offshore of the LRIS in Lake River are described below.

- **Recreationists.** The water recreation scenario includes personal watercraft, water skiing, kayaking, swimming, and other beach activities. The primary exposure medium for these activities is water, but individuals may also come into contact with sediment while entering or exiting the water. Adults and children may be recreationists.

  Recreationist exposure to dioxins in sediment likely is limited, as use of nearshore LRIS areas and/or sustained contact with sediment near the LRIS is unlikely. Although the recreationist pathway is not likely to be significant, CULs protective against direct contact with dioxins in sediment are developed as a precaution (see the discussion of CUL development in Section 6).

- **Fishers.** Fishers generally angle near the LRIS by boat or from nearby piers, using hook and line. Fish may be caught for personal consumption. Because of the strongly hydrophobic nature of dioxins, exposure to fishers via surface water is not expected to be a significant pathway. The primary exposure media for potential fishers are aquatic biota; direct contact with surface water and sediment is considered an insignificant pathway. Fishers may include adults and children.

  Fishing is allowed in RNWR areas open to the public (on the Carty Unit), including sections of Lake River. Under the RNWR 2010 Comprehensive Conservation Plan, the RNWR will evaluate fishing access enhancement opportunities in the River "S" Unit located west and southwest of the Site. This may result in an increase in fishing visits at Lake River, although presently there are only approximately 260 fishing visits annually throughout the entire area of the RNWR that is open to the public (i.e., the Carty Unit) (USFWS, 2010).

  The frequency of fishing activity in Lake River sections outside the RNWR is not known; however, fishing in the region is more popular in the cold waters of the Columbia River. Harvestable resident fish and shellfish species known to exist in Lake River include common carp, channel catfish, largescale sucker, and crayfish (USFWS, 2010). Of these, the largescale sucker and the crayfish have relatively small home ranges and would be most relevant to evaluation of site-related seafood health risks. The channel catfish and the common carp, by contrast, tend to have large home ranges that would limit the influence of the LRIS site sediments on tissue quality or human health exposures.

  With the potential exception of crayfish, shellfish are not expected to be relevant to human health exposures. The USFWS (Buck, 2000) attempted to sample Asian clams (*Corbicula fluminea*) in Lake River adjacent to the PWT site, but none were found at any of the sampling locations. The WDFW (as cited in Ecology, 2011c) reports no recreational take of shellfish from the Columbia River in 2006. While freshwater mussels were an important dietary component of Columbia River and Snake River tribes, neither mussels nor the invasive Asian clam have been noted in Lake River. Therefore it is unlikely that these species will contribute to potential human health risks.

  Lake River is not a documented usual and accustomed fishing ground for tribes. However, tribes may have an interest in the area and will be included in the cleanup decision-making process. Anadromous and freshwater finfish constitute most of the fish consumed by Columbia River region tribal members (Ecology, 2011c). Columbia River tribal consumption surveys did not report the consumption of shellfish (i.e., crayfish). Salmon was reported to be consumed by the largest number of tribal adult respondents (92 percent), followed by trout (70 percent), lamprey (54 percent), and smelt (52 percent). Because the potential return for fishing in Lake River is low, it is most likely that recreational and subsistence fishers will maximize their limited resources (i.e., time and fuel) by fishing in the substantially more productive Columbia River. In addition, while species such as crayfish and largescale sucker are present in Lake River, it is important to consider that relatively low species production rates and the long lifespan of these species will tend to limit potential fishing success (and resulting diet fraction) of fishers who elect for whatever reason to target their fishing activity near the LRIS.

Development of CULs protective of recreational fisher consumption of fish that have accumulated dioxins in tissue are discussed in Section 6.

Ecological Receptor CSM

Water-dependent ecological receptors, including plants, benthic invertebrates, fish (piscivorous, omnivorous, and benthivorous), piscivorous mammals, and piscivorous raptors are ecological receptors most likely to become exposed to dioxin-impacted sediment offshore of the LRIS.

Relevant exposure media for ecological receptors include sediment and also fish tissue for receptors at higher trophic levels. As indicated above, plants, benthic invertebrates, fish, birds, and mammals may all be exposed to dioxins present in sediment. Specifically, plants and benthic invertebrates may be exposed to dioxins through direct contact with and uptake from sediment; fish may be exposed to dioxins through direct contact with sediment and ingestion of food that has accumulated contaminants. Birds and mammals may be exposed to dioxins through incidental ingestion of sediment and consumption of food that has accumulated the contaminant. Although birds and mammals may have some dermal exposure to dioxins in sediment, this exposure route is considered insignificant because of external protection such as fur and feathers.

Considerable toxic effect has been demonstrated for fish, birds, and mammals exposed to dioxins (USEPA, 2008). However, plants and benthic invertebrates are relatively insensitive to dioxin-induced toxicity (USEPA, 2008), and no relationship to benthic toxicity has been established (Avocet, 2011). CULs developed (see Section 6) for protection of the more susceptible ecological receptors (i.e., fish, birds, and mammals) are also expected to be protective of the less susceptible plants and benthic invertebrates.

As discussed above, the largescale sucker and crayfish have relatively small home ranges and would be most relevant to evaluation of site-related impacts to aquatic biota. Common waterbird species and raptors that use wetlands along Lake River and that likely would be fish/shellfish consumers include coot, pied-billed grebe, double-crested cormorant, great blue heron, great egret, bald eagle, osprey, and northern harrier. Mammals that inhabit wetlands along Lake River and that have the potential to ingest fish/shellfish include mink, muskrat, river otter, common opossum, raccoon, and striped skunk (see Appendix C).

Lake River Summary

The following exposure pathways and receptors are selected for further evaluation and CUL development:

- Human direct contact with sediment and incidental sediment ingestion
- Human secondary ingestion (consumption of chemicals in tissue of aquatic biota)

- Fish uptake of chemicals in sediment
- Bird or mammal secondary ingestion (consumption of chemicals in aquatic prey)

5.6 Carty Lake Exposure Scenarios

Carty Lake is located on the RNWR north of Cell 2 and west of Cell 4 (see Figure 2-3). Carty Lake is a 52-acre, ponded wetland. During most of the year Carty Lake has no outlet, but during the rainy season it can be hydraulically connected to Gee Creek at the lake's northern end. Carty Lake has limited recreational uses (USFWS, 2010) (i.e., it is accessible by trails and fishing is allowed, but boating is not allowed). Carty Lake's setting, fluvial dynamics, and uses are further described in Section 2.

Dioxins are identified as IHSs for Carty Lake sediment (see Section 3.5.3.1). Dioxins were detected in all samples and were significantly elevated in the southern portion of the lake, but decreased substantially in concentration farther north. Other contaminants at elevated concentrations are colocated with the highest dioxin concentration (1,400 ng/kg dioxin TEQ at LRIS-CL-02), and any cleanup action directed at dioxins is expected to remedy these contaminants.

The relevant exposure point for Carty Lake is surface sediment with elevated concentrations of dioxins and other chemicals. Potential exposure pathways for human health and ecological receptors are described below. Exposure scenarios are shown in Figure 5-1.

Human Health CSM

The principal potential receptors at Carty Lake are discussed below.

- **Fishers.** While there is potential for fishers (recreational) to angle in Carty Lake, fishing for consumption is likely to be very limited. Uses in the Carty Unit of the RNWR include hiking and fishing; however, there are only about 260 fishing visits annually throughout the entire RNWR, with use distributed between Gee Creek, Duck Lake, Middle Lake, and Carty Lake (USFWS, 2010), suggesting that public use activities near or in Carty Lake are currently uncommon. Trails lead to the Gee Creek portion of the Carty Unit for fishing, but Carty Lake itself is not currently readily accessible to visitors. The RNWR maintains a mowed seasonal footpath along the north end of the lake, but this path is flooded during high-water periods and is not heavily used; however, the RNWR could work with the Port to develop a loop trail adjacent to Carty Lake for public access from the Port property. A few individuals have been observed fishing on an irregular and seasonal basis (Chmielewski, 2011), and possible catch includes common carp, largescale sucker, and crayfish. However, it is not known if fish are caught for consumption (USFWS, 2010).

  In the future, the USFWS may consider the feasibility of reconnecting Carty Lake either to the Columbia River via Gee Creek or to Lake River through a constructed channel (see Section 2.8.4). A Gee Creek connection likely would restore access for salmonids such as cutthroat trout and coho salmon, in which case future potential fish catch and consumption of these desirable species would require examination, although limited access and preference for Columbia River fishing (see Section 5.5 above) may continue to limit fishing activity.

Because of the strongly hydrophobic nature of dioxins, exposure to fishers via surface water is not expected to be a significant pathway. The primary exposure media for potential fishers are aquatic biota; direct contact with surface water and sediment is considered an insignificant pathway. Fishers may include adults and children.

- **Restoration workers.** Recreationist activity at Carty Lake likely is extremely limited and exposure to dioxins in sediment likely is not significant. However, the USFWS may attempt to remove nonnative vegetation (i.e., tilling reed canary grass) and restore native wapato in the future, potentially resulting in direct contact with and incidental ingestion of sediment. Restoration efforts likely would involve tilling vegetation for a 40-hour work week about once every three years (USFWS, 2012).
- **Tribal use.** The Cowlitz Tribe historically used Carty Lake for wapato harvest and may want to use the area for this purpose in the future (Mercuri, 2012). In the event that Tribal members choose to harvest and consume wapato, they may be exposed to impacted sediment via direct contact and incidental ingestion of sediment during harvest activities. However, ingestion of wapato grown in impacted sediment is not expected to be a significant exposure pathway because studies have shown that dioxins are not incorporated into any substantial fraction of the edible plant material (Paustenbach et al., 2006). The frequency and duration of potential future harvesting activities are not known.

Ecological Receptor CSM

Carty Lake ecological functionality has been reduced because of diking and filling, and water quality and aquatic plants have been negatively impacted by introduced carp (USFWS, 2010). However, Carty Lake provides habitat for plants, benthic invertebrates, fish (piscivorous, omnivorous, and benthivorous), piscivorous mammals, and piscivorous raptors.

Relevant exposure media for receptors include sediment and also fish tissue, in the case of receptors at higher trophic levels. Plants, benthic invertebrates, fish, birds, and mammals may all be exposed to dioxins in sediment. Specifically, plants and benthic invertebrates may be exposed to dioxins through direct contact with and uptake from sediment; fish may be exposed to dioxins through direct contact with sediment and ingestion of food that has accumulated contaminants; and birds and mammals may be exposed to dioxins through incidental ingestion of sediment and consumption of food that has accumulated dioxins. Although birds and mammals may have some dermal exposure to dioxins in sediment, this exposure route is considered insignificant because of external protection such as fur and feathers.

Considerable toxic effect from dioxins has been demonstrated for fish, birds, and mammals (USEPA, 2008). However, plants and benthic invertebrates are relatively insensitive to dioxin-induced toxicity (USEPA, 2008), and no relationship to benthic toxicity has been established (Avocet, 2011). Actions to remedy contamination, developed for the more susceptible ecological receptors (i.e., fish, birds, and mammals), will account for protection of the less susceptible plants and benthic invertebrates.

As discussed above, the largescale sucker, common carp, and crayfish in Carty Lake likely have relatively small home ranges and would be most relevant to evaluation of site-related impacts to aquatic biota. In the event that a connection between Carty Lake and the Columbia River is restored (see Section 2.8.4), access for salmonids such as cutthroat trout and coho salmon could be achieved. Common waterbird species and raptors that utilize habitat along Carty Lake and that may ingest fish/shellfish include coot, pied-billed grebe, double-crested cormorant, great blue heron, great egret, bald eagle, osprey, and northern harrier. Mammals that inhabit wetlands along Carty Lake and that have the potential to consume fish/shellfish include mink, muskrat, river otter, common opossum, raccoon, and striped skunk (see Appendix C).

Carty Lake Summary

The following exposure pathways and receptors are selected for further evaluation and CUL development:

- Human secondary ingestion (consumption of chemicals in tissue of aquatic biota)
- Restoration worker direct contact with sediment and incidental ingestion of sediment
- Fish uptake of chemicals in sediment
- Bird or mammal secondary ingestion (consumption of chemicals in aquatic prey)

6 PRELIMINARY CLEANUP LEVELS AND POINTS OF COMPLIANCE

A CUL is the concentration of a hazardous substance in soil, water, air, or sediment that is determined to be protective of human health and the environment under specified exposure conditions. CULs, in combination with POCs, typically define the area or volume of soil, water, air, or sediment at a site that must be addressed by the cleanup action (WAC 173-340-700 through 173-340-760). Cleanup standards must also incorporate other state and federal regulatory requirements applicable to the cleanup action and/or its location. POCs are identified in accordance with standard MTCA protocols for soil and groundwater, and consistent with the SMS for affected sediments.

This section first describes preliminary soil and groundwater CULs protective of potential receptors in upland portions of the Site. MTCA includes procedures for developing standard and modified Method B and Method C risk-based CULs for media, including residential soils, industrial soils, and groundwater (Chapter 173-340-700 WAC).

Preliminary CULs are also developed for sediments in Lake River and Carty Lake. MTCA addresses sediment CULs by reference to the SMS (Chapter 173-204 WAC). While SMS CULs have been developed for marine sediments, freshwater sediment quality criteria are currently determined on a case-by-case basis (Chapter 173-204-340 WAC). Cleanup standards consider protection of human health and ecological receptors.

6.1 Soil

Under the standard MTCA Method B, generic default assumptions are used to calculate risk-based CULs protective of human health. Modified Method B provides for the use of chemical-specific or site-specific information to change selected default assumptions, within the limitations allowed in WAC 173-340-708. Modified Method B may be used to establish CULs. Method C industrial soil CULs may also be established at industrial properties that meet the criteria in WAC 173-340-745.

6.1.1 LRIS

As reported in previously submitted LRIS RI/FS reports (MFA 2007, 2010e, 2011a), on-site preliminary CULs for soil were selected based on the applicable endpoints of direct contact via ingestion or dermal contact by humans (Ecology, 2011e). Soil CULs are presented in Table 6-1. Future development likely will not be industrial. Therefore, Method C CULs are not applicable. Similarly, Method A CULs are not considered applicable for most chemicals because of site complexity (e.g., relatively large size and multiple hazardous substances). With a few exceptions, standard Method B direct-contact CULs are applied to soil on the LRIS.

MTCA Method B CULs are not available for petroleum mixtures. The only standard CULs for petroleum mixtures are MTCA Method A Unrestricted Use values. Therefore, Method A soil CULs are used for petroleum hydrocarbon mixtures (2,000 mg/kg for RROs and DROs). The MTCA Method B direct-contact CUL (0.67 mg/kg) for arsenic is below natural background concentrations in soil. Therefore, the natural background concentration of arsenic in Clark County of 5.81 mg/kg (Ecology, 1994) is used as the CUL. Based on the MTCA Method B carcinogen standard formula value for direct contact (ingestion only), unrestricted land use value, the soil CUL for cPAHs (i.e., benzo(a)pyrene and cPAH TEQ) is 0.14 mg/kg; for PCP, 8.3 mg/kg; and for dioxins (i.e., dioxin TEQ), 11 ng/kg.

Leaching from soil to groundwater is a potentially complete endpoint for IHSs in soil. However, it should be noted that the CULs for soil leaching to groundwater are developed using simple models that often overpredict soil concentrations as reasonably likely to cause unacceptable groundwater impacts. Direct measurements of groundwater quality at the LRIS have been made consistently since 2004, and available evidence indicates that the chemicals in groundwater likely are stable or declining over time. Further, because the contaminants were released to soil in 1998 or earlier and have been exposed to precipitation since then, it is likely that the concentrations of IHSs in soil are stable and that any leaching of IHSs from the soil has already reached a state of equilibrium. For these reasons, while the endpoint is potentially complete, the soil leaching to groundwater CULs are not necessary to protect groundwater at the LRIS. However, at Ecology's request, the CULs are presented for completeness.

It was assumed that a hypothetical terrestrial ecological receptor could contact soil at the LRIS at some point in the future. Therefore, a TEE was completed for the LRIS to evaluate options that would be protective of ecological receptors (see Appendix B). MTCA EICs protective of wildlife were selected as CULs if more protective than MTCA Method B CULs.

Point of Compliance. The soil POC is the depth bgs at which soil CULs will be attained. The standard POC for Method B is soil within 15 feet of the ground surface throughout the entire Site.

6.1.2 Off-Property

Dioxins were identified as an IHS for the upland off-property (see Section 3.2.2.1). The upland off-property area includes Port-owned properties and non-Port-owned properties. The Port-owned properties have a mixed waterfront use designation, while the non-Port-owned properties are primarily residential.

6.1.2.1 Port-owned Properties

The preliminary soil CULs are presented in Table 6-2, and Figure 6-1 shows exceedances of human health CULs. CULs for soil were selected based on the applicable endpoints of direct contact via ingestion or dermal contact by humans. Method A CULs are not applicable for dioxins, and Method C CULs are not applicable because future development likely will not be industrial. Therefore, the dioxin TEQ of 11 ng/kg is selected as the preliminary Port-owned properties human health CUL, based on the MTCA Method B level. Note that human health CULs are based on standard default calculations applicable to all sites, yet exposures to residents on Port-owned properties may be significantly less than in residential areas because of less frequent use (see Section 5.4.1).

CULs protective of ecological receptors are presented as a dioxin TEQ (herein referred to as EIC dioxin TEQ) and a furan TEQ (EIC furan TEQ). A TEE determined site-specific criteria of 9.8 ng/kg EIC dioxin TEQ and 11.4 ng/kg EIC furan TEQ, respectively (see Appendix B). These concentrations were selected as preliminary ecological CULs. As indicated in the TEE provided in Appendix B, there may be unacceptable risk if ecological receptors are exposed to soil on the Railroad Avenue property.

Points of Compliance. The POC for human exposure via direct contact is 0 to 15 feet bgs for soil throughout the off-property (WAC 173-340-740 (6)(d)). The POC for ecological exposure is the biologically active zone of 0 to 6 feet bgs for soil (WAC 173-340-7490).

6.1.2.2 Non-Port-owned Properties

Previous soil characterization activities in non-Port-owned properties have focused primarily on rights-of-way in the residential area (see Section 3.2.2.2).[5] Additional characterization is being contemplated in yards of residential areas. Because characterization is not complete, CULs for non-Port-owned properties are not being developed at this time.

---

[5] Several samples were also collected in McCuddy's Marina and on RNWR property. McCuddy's Marina soil is marginally above the MTCA Method B CUL and RNWR soil concentrations are well below MTCA Method B (see Section 3.2.2.2). Further characterization activities developed for residential areas will consider additional sampling on the McCuddy's Marina property.

6.2 Groundwater

As described above, MTCA provides three different options for establishing CULs for human health: Method A, Method B, and Method C. Future development on the LRIS may not be of an industrial nature. Therefore, Method C CULs are not considered to be applicable. Similarly, Method A CULs are not considered applicable for most chemicals because of site complexity (e.g., relatively large size and multiple hazardous substances). With a few exceptions, Method B CULs are applied to groundwater (see Table 6-1). In addition, Method B groundwater guidance screening levels protective of indoor air (Ecology, 2009) are compared with concentrations of VOCs in groundwater. Vapor intrusion screening levels are also expected to be protective of human health for those who may be exposed to vapors migrating to outdoor air, given the significant mixing with ambient air that is expected to occur in the outdoor environment. These CULs are calculated using reasonable maximum human health exposure assumptions with target risk levels set at the MTCA acceptable risk level.

As discussed in Section 5.2.3, the only surface water body that receives groundwater recharge is Lake River. The shallow portion of the UWBZ discharges to Lake River. The deeper UWBZ and the LWBZ flow beneath Lake River. Groundwater from the UWBZ and LWBZ flows beneath the southern portion of Carty Lake. Therefore, groundwater results from wells near Lake River and Carty Lake are compared to the following surface water screening levels:

- MTCA Method B groundwater and surface-water CULs (Ecology, 2011e)
- USEPA national recommended WQC for freshwater CCC for aquatic organisms, for HH consumption of organisms only, and for HH consumption of organisms and water (USEPA, 2009)

As discussed in Section 3, MFA modeled groundwater transport of arsenic, BEHP, benzene, chromium, dibenzofuran, PCP, and PCE, the most widespread of the site-related chemicals, to evaluate the potential for these chemicals to impact surface water of Lake River. Using conservative modeling assumptions outlined in the Cells 1 and 2 RI/FS (MFA, 2011a) and the Cell 3 RI (MFA, 2007), these chemicals are not expected to discharge at concentrations that would adversely impact human health or the environment (see Section 5.2.3).

Petroleum hydrocarbons are not included in the above-mentioned screening levels or CULs; therefore, MTCA Method A groundwater CULs were compared to petroleum hydrocarbon concentrations.

The MTCA Method B groundwater CUL for arsenic is below natural background concentrations in groundwater. The MTCA Method A groundwater CUL is based on naturally occurring arsenic throughout Washington; therefore, the Method A CUL of 5 μg/L is used as the CUL.

Point of Compliance. The POC for groundwater is the entire UWBZ and LWBZ at the Site (WAC 173-340-720(8)(b)). A conditional POC may be established if it is not practicable to meet the CUL throughout the Site within a reasonable restoration time frame (WAC 173-340-720(8)(c)). The proposed conditional POC for groundwater is located in the UWBZ and the LWBZ at the top of the bank along the western boundaries of Cell 2 and Cell 3. In addition, five monitoring wells will be monitored north of Cell 2 in the RNWR and one well on the southern boundary of Cell 3. POC monitoring wells include the following:

- **Cell 2:** MW-55, MW-55S, MW-55D, MW-56, MW-57S, MW-57D, MW-58D, and MW-62
- **Cell 3:** MW-29D, MW-45D, MW-46S, MW-46D, and MW-47D
- **RNWR:** RMW-2S, RMW-2D, MW-61, MW-63, and USDFW-1

6.3 Sediment

Dioxins were identified as an IHS in Lake River and Carty Lake sediments. Dioxins are known carcinogens that bioaccumulate in food chains, and they are colocated with elevated concentrations of other contaminants (see Sections 3.5.2 and 3.5.3). Therefore, any remedy directed at dioxins is expected to remedy other contaminants that exceed screening levels. CUL development for dioxins is described below.

The criteria, methods, and procedures necessary for the development of freshwater benthic sediment CULs are currently determined on a case-by-case basis under SMS (WAC 173-204-520 (1)(d)). This topic is subject to ongoing regulatory development by Ecology in an effort to harmonize MTCA and SMS procedures. A benthic sediment CUL was not established for dioxins (identified as an IHS for Lake River and Carty Lake), as appropriate benthic toxicity criteria are currently unavailable.

MTCA defines specific procedures for the development of risk-based CULs for media such as soils and groundwater. However, procedures for developing human health or ecological risk-based CULs for sediments are not currently defined. As rule-making is still under development, CULs are currently set on a case-by-case basis. Here an effort was made to follow the overall MTCA approach for risk-based CUL development while integrating recent science for freshwater sediment. This direction is consistent with the potential new rule language.

Under MTCA, risk-based Method B CULs are established using a 1×10^{-6} excess cancer risk; human health risk-based CULs for dioxins in sediment (measured as dioxin TEQ) were therefore established using a 1×10^{-6} cancer risk. Ecological risk-based CULs were developed for dioxin congeners, using standard USEPA models and MTCA defaults, when available. See Appendix M-1 for further details on human and ecological risk-based models.

MTCA regulations specify that where risk-based CULs are less than natural background levels, or where they are less than the achievable practical quantitation limit (PQL), the CULs shall be established at concentrations equal to the natural background concentration or the PQL, whichever is higher (WAC 173-340-700, 706, 707). Natural background and the PQL for dioxins were determined following MTCA procedures as described in Appendix K and Appendix M-2, respectively. Ecology conducted additional evaluation and analysis of PQLs for dioxins beyond the evaluation presented in Appendix M-2 and agrees that the value as determined (5 ng/kg dioxin TEQ) is a reasonably achievable PQL to be used as a quantifiable CUL.

6.3.1 Lake River

Because elevated dioxin concentrations are colocated with elevated concentrations of other contaminants (see Section 3.5.2), CULs and associated actions set for dioxins are expected to address all areas impacted by other contaminants.

The risk-based CUL development focuses on exposure of human and ecological receptors to dioxins in sediment and tissue, while exposure to dioxins in surface water is considered negligible (see Section 5.5). Specifically, CULs were developed for the receptors, identified in the CSM, with significant exposure pathways and/or sensitivity to dioxins (i.e., recreationists, fishers, fish, piscivorous birds, and piscivorous mammals). The CUL must be at least as stringent as established state or federal standards or other laws. Some applicable or relevant and appropriate requirements (ARARs) contain numerical values or methods for developing such values; however, there are no ARARs for sediment.

Risk-based preliminary CULs were developed for:

- Human direct contact with sediment and incidental sediment ingestion
- Human secondary ingestion (consumption of chemicals in tissue of aquatic biota)
- Fish uptake of chemicals in sediment
- Bird or mammal secondary ingestion (consumption of chemicals in aquatic prey)

Risk-based preliminary CUL development methods and assumptions are described in Appendix M-1. Preliminary CULs are summarized in Table 6-3. The preliminary risk-based CULs protective of human consumption of fish are based on standard, default assumptions commonly used and in MTCA rules. Limited site-specific assumptions, where applicable, are integrated into CUL models, although models do not represent refined site-specific risk analysis. As detailed in Appendix M-1, development of risk-based, site-specific sediment CULs would require substantial work and would include development of a risk-receptor relationship quantifying the potential links between sediment quality and fish tissue quality, and between fish tissue quality and potential human exposures. Some elements of this relationship have already been developed as part of the Lake River 2010 RI CSM (Anchor and MFA, 2011). However, additional information would be needed to appropriately develop a more exact, site-specific, risk-based CUL for sediments that is based on human fish consumption. Additional details are provided in Appendix M-1.

To evaluate potential adverse ecological effects at higher trophic levels (e.g., piscivorous birds and mammals) resulting from dioxins in sediment, expected concentrations in tissue were modeled, applying default or site-specific assumptions. Ecological CULs based on default assumptions or site-derived data were developed using standard USEPA models on a congener-specific basis (DEQ, 2007; USEPA, 1989; WAC 173-340-740). Models and assumptions used to generate ecological CULs are further described in Appendix M-1.

As described in Section 6.3, considerations of natural background inputs and analytical constraints affect CUL selection for dioxins. Evaluations of background levels and dioxin PQLs are presented in Appendix K and Appendix M-2, respectively. Appendix K shows that natural background is

2 ng/kg dioxin TEQ. The PQL (developed in consultation with Ecology), the concentration at which dioxin TEQs can be measured reliably, is 5 ng/kg. Both background (2 ng/kg) and PQL (5 ng/kg) levels exceed the preliminary risk-based CUL for fish ingestion and are below the preliminary CUL protective against human direct contact with and incidental ingestion of sediment (Table 6-3). WAC 173-340-700(6d) states that when risk-based CULs are less than natural background levels or levels that can be reliably measured, then the CUL shall be established at a concentration equal to the PQL or natural background concentration, whichever is higher. Therefore, the preliminary human health dioxin CUL is 5 ng/kg dioxin TEQ. Lake River sample locations and CUL exceedances are shown in Figure 6-2.

Ecological congener-specific CULs are presented in Table 6-3; the value protective of fish, bird, and mammal populations was selected as the CUL for each congener. Human health and ecological CUL exceedances are shown in Table 6-4. Table 6-4 and Figure 6-2 show that ecological CUL exceedances are less frequent than human health CUL exceedances and occur only in areas where dioxin TEQs are elevated. Therefore, any remedy directed at addressing sediment exceeding the human health CUL is expected to mitigate unacceptable risk to ecological receptors as well.

Point of Compliance. According to SMS requirements, the POC is represented by the biologically active sediment zone within the uppermost 10 cm bml. This includes protection from potential exposure to deeper contaminants and to contaminant migration.

6.3.2 Carty Lake

Because elevated dioxin concentrations are colocated with elevated concentrations of other contaminants (see Section 3.5.3.1), CULs set for dioxins, and associated actions, are expected to address other contaminants above screening levels.

The risk-based CUL development focuses on exposure of receptors to dioxins in sediment and tissue, while exposure to dioxins in surface water is considered negligible. Specifically, preliminary risk-based CULs were developed for the receptors, identified in the CSM, with potentially significant exposure pathways and/or sensitivity to dioxins (i.e., human direct contact, fish, piscivorous birds, and piscivorous mammals). A risk-based human fish consumption CUL was not developed, as human consumption rates for Carty Lake are unavailable. To account for potential risk resulting from human consumption of fish, hypothetical scenarios based on models developed for Lake River (see Section 6.3.1) were evaluated, including the amount of fish that could be consumed at current Carty Lake dioxin levels to meet acceptable risk levels (see Appendix M-1 for details). A CUL must be at least as stringent as established state or federal standards or other laws. Some ARARs contain numerical values or methods for developing such values; however, there are no numerical ARARs for dioxins in sediment.

Preliminary risk-based CULs were developed for:

- Human direct contact with sediment and incidental ingestion of sediment. This pathway is based on a restoration worker scenario; see Section 2.8.4 for a description of restoration activities that may be conducted at Carty Lake.
- Fish uptake of chemicals in sediment.
- Bird or mammal secondary ingestion (consumption of chemicals in aquatic prey).

Preliminary risk-based CUL development methods and assumptions are described in Appendix M-1. Preliminary CULs are summarized in Table 6-5.

To evaluate potential adverse ecological effects at higher trophic levels (e.g., piscivorous birds and mammals), expected dioxin concentrations in tissue were modeled, applying default or site-specific assumptions. Ecological CULs based on default assumptions or site-derived data were developed using standard USEPA models on a congener-specific basis (DEQ, 2007; USEPA, 1989; WAC 173-340-740). Models and assumptions used to generate CULs are further described in Appendix M-1. As detailed in Section 6.3, considerations of natural background inputs and analytical constraints may also impact CULs. Evaluations of background levels for Lake River and dioxin PQLs are presented in Appendix K and Appendix M-2, respectively. A natural background evaluation for Carty Lake has not been conducted and is not anticipated, given the lack of available dioxin sediment data in regional lakes. However, the background level in the Lower Columbia River has been established at 2 ng/kg dioxin TEQ. The PQL (the concentration at which dioxin TEQs can be measured reliably) is 5 ng/kg dioxin TEQ.

Evaluations of human fish consumption scenarios at Carty Lake (see Appendix M-1) indicate that a human health risk-based CUL may be below natural background or the PQL, while the preliminary risk-based CUL protective of human direct contact is higher than natural background or the PQL (see Table 6-5). WAC 173-340-700(6d) states that when risk-based CULs are less than natural background levels or levels that can be reliably measured, then the CUL shall be established at a concentration equal to the PQL or natural background concentration, whichever is higher. Therefore, the human health dioxin CUL is based on the PQL of 5 ng/kg dioxin TEQ. Carty Lake sample locations and CUL exceedances are shown in Figure 6-3.

Ecological congener-specific CULs are presented in Table 6-5; the value protective of fish, bird, and mammal populations was selected as the CUL for each congener. Human health and ecological CUL exceedances are shown in Table 6-6. Dioxin congeners are found at levels below risk-based CULs at all locations except the area comprising LRIS-CL-01, -02, and -04, where highly elevated dioxin TEQs occur (see Section 3.5.3.1). Thus actions directed at remedying elevated dioxin TEQs are expected to account for potential risk both to human health and to ecological receptors.

Point of Compliance. According to SMS requirements, the POC is represented by the biologically active sediment zone within the uppermost 10 cm bml. This includes protection from potential exposure to deeper contaminants and to contaminant migration.

7 SUMMARY OF LRIS FEASIBILITY STUDIES

This section presents the results of the feasibility analyses conducted for soil and groundwater for the LRIS property. FSs have been conducted and reports submitted to Ecology for Cells 1 and 2, and separately for Cell 3 and Cell 4. Detailed descriptions of the development of the studies, including cost estimates, are provided in these three FS reports. Most of the interim actions for Cells 1, 2, 3, and 4 have been completed, as discussed in Section 4. The remedial alternatives are presented below as they were in their respective FS reports, except where noted. Preferred alternatives may have been altered slightly, based on site conditions or as discussed with Ecology during implementation.

The draft FS for Cells 1 and 2 was submitted on January 19, 2011 (MFA, 2011a). Ecology provided verbal comments on March 3, 2011, and indicated that additional comments were forthcoming. The discussion of Cells 1 and 2 presented below is a summary of the draft FS with the alternatives slightly revised to address comments received from Ecology. An interim action work plan was prepared for Cells 1 and 2 (MFA, 2011b) and approved by Ecology in June 2011, based on the preliminarily preferred alternative from the draft Cells 1 and 2 FS. Interim actions described in Section 4.4 are near completion.

The final FS for Cell 3 was submitted to Ecology on June 3, 2011 (MFA, 2011c). The final FS for Cell 4 was submitted to Ecology on November 29, 2010 (MFA, 2010e), and approved by Ecology on December 17, 2010 (Ecology, 2010b). Interim actions consistent with the remedial alternatives recommended in the Cell 3 FS and the Cell 4 FS were developed into an Ecology-approved (in June 2011) interim action work plan (MFA, 2010c) and were completed in 2010 and 2011 (see Section 4.3). Although final FSs for Cells 3 and 4 have been completed, the feasibility analysis is summarized below for completeness. See Section 4.3 for a description of interim actions completed in Cells 3 and 4.

CULs for Cells 1, 2, 3, and 4 are developed and presented in Section 6. Potential RELs were identified for Cells 3 and 4. RELs may be developed as part of the cleanup action alternatives to be considered during the FS. An REL, according to WAC 173-340-200, is a concentration (or other method of identification) of a hazardous substance in soil, water, air, or sediment above which a particular component will be required as part of a cleanup action at a site. In accordance with WAC 173-340-355, the remedial action that includes RELs must still comply with cleanup standards, including the requirement that CULs be met at the applicable POCs.

According to WAC 173-340-355(4), these potential RELs may be defined as a concentration or another method of identification of a hazardous substance. Quantitative or qualitative methods may be used to develop these potential RELs. These methods may be simple or complex, as appropriate to the LRIS.

Based on the MTCA Method C Carcinogen Industrial Land Use Table Value (direct contact), the soil REL for arsenic is 88 mg/kg; for cPAHs (i.e., benzo(a)pyrene and cPAH TEQ), 18 mg/kg; for

PCP, 1,100 mg/kg; and for dioxins (i.e., dioxin TEQ), 1,500 ng/kg. In addition, the presence of NAPL is set as an REL.

7.1 Remedial Alternatives

7.1.1 Cells 1 and 2

Five remedial alternatives were developed that meet cleanup standards for Cells 1 and 2. As discussed in Section 4.4, an interim action work plan (based on Alternative 2B, [MFA, 2011b]) was developed for Cells 1 and 2. The remedial alternatives are described below:

Alternative 1: Capping, Groundwater Monitoring, and Institutional Controls

- Cells 1 and 2 would be capped with a minimum of 2 feet of soil and a geotextile (i.e., a permeable cap) or an equivalent exposure barrier (e.g., liner, asphalt, concrete, building).
- Equivalent exposure barriers for potential types of use are provided in Table 7-1 (note: the capping sections described were consistent in the FS documents for Cells 1, 2, 3, and 4. When capping is discussed in this document, it is synonymous with the sections described in Table 7-1, but for brevity these sections are not repeated in each capping discussion.)
- The existing stormwater system would be removed to address IHS exceedances; this would include removal of a stormwater catchment. A new stormwater system incorporating engineering controls would be installed.
- Steam would be injected in the entire SER area to polish areas previously treated and to ensure capture of residual mobile NAPL. Once diminishing returns are observed, demobilization of the SER system would be phased to coordinate with site capping activities. Post-demobilization sampling would be conducted to better define conditions for the SMP and institutional controls. The SER system would be dismantled and decommissioned.[6]
- Groundwater monitoring would be completed at the proposed POC monitoring wells to assess whether contaminants are stable and reducing. Monitoring wells other than the proposed POC would be decommissioned as part of remedial activities. Table 3-7 shows the proposed POC monitoring wells and the analytes that would be sampled from each. Note that this POC table was modified based on discussions with Ecology after the interim action was completed. Figure 2-12 highlights the POC monitoring wells. The wells would be sampled semiannually for two years and then approximately every 18 months to evaluate seasonal variation. Sampling would be conducted during the observed high- and low-water events on the LRIS (i.e., January and August, respectively).

---

[6] As approved by Ecology (Ecology, 2011b), steam injection has ceased (see Section 4.2), dismantling and decommissioning have begun, and post-demobilization sampling has been completed (see Section 4.4).

- Institutional controls would be implemented as part of the remedial action. These would be in the form of restrictive covenants to provide options for vapor mitigation for future construction, which would require adherence to an SMP for protection and maintenance of surface capping and management of residual contaminated soils during redevelopment or subsurface work. Institutional controls would also prohibit groundwater use. Upon approval from the City, historical city drinking wells east of the LRIS would be abandoned.[7] Via institutional controls, ingestion of drinking water would become an incomplete pathway.

Alternative 2A: Targeted Removal, Capping, Groundwater Monitoring, and Institutional Controls

- Soil in the concrete pond area with historically observed NAPL would be excavated, transported, and disposed of at a licensed facility. The excavation would extend to 15 feet bgs, which is 3 feet below the typical water table depth in the area, and would remain open to allow removal of floating product. For the purposes of the cost estimate, soil from the concrete pond excavation is presumed to require treatment before landfilling at a Subtitle C disposal facility. This waste may be considered a Corrective Action Management Unit (CAMU)-eligible waste, which could alter the disposal requirements.[8] Excavations would be backfilled using clean backfill and unimpacted overburden.
- Cells 1 and 2 would be capped as discussed in Alternative 1.
- The existing stormwater system would be removed as described in Alternative 1.
- The SER system would operate and be decommissioned as described in Alternative 1.
- Groundwater monitoring would be completed as described in Alternative 1.
- Institutional controls would be implemented as part of the remedial action. These would be in the form of a restrictive environmental covenant to provide options for vapor mitigation for future construction, and would require adherence to cap maintenance and an SMP for protection and maintenance of surface capping and management of residual contaminated soils during redevelopment or subsurface work. Institutional controls would also prohibit groundwater use. The institutional controls may vary by cell, based on the sampling results, to ensure that the implemented remedy is protective of human health and the environment.

---

[7] The City abandoned these drinking wells in 2011.

[8] During remedial design, the Port worked with Ecology to establish CAMU eligibility (see Appendix N for CAMU eligibility documentation); however, cost estimates did not assume that CAMU eligibility would be established.

Alternative 2B: Targeted Removal, Capping, Groundwater Monitoring, and Institutional Controls

- Soil in the concrete pond area would be excavated, transported, and disposed of as described in Alternative 2A.
- Shallow soil near sample locations SS-14 and TP-03 contained dioxins and PCP, respectively, that exceeded Method C soil CULs. This soil would be excavated, transported, and disposed of at a licensed facility. The SS-14 excavation would extend to 1 foot bgs and would be approximately 20 feet by 20 feet. The TP-03 excavation would extend to 1 foot bgs and would be 10 feet by 10 feet. The soil from these areas is associated with the former PWT wood-treatment operations, and is considered to be an F032-, F034-, and F035-listed waste. For the purposes of the cost estimate, the soil is assumed to require off-site treatment (organic vapor recovery) before disposal at a Subtitle C facility. This waste may be considered a CAMU-eligible waste.[9]
- Cells 1 and 2 would be capped as discussed in Alternative 1.
- The existing stormwater system would be removed as described in Alternative 1.
- The SER system would operate and be decommissioned as described in Alternative 1.
- Groundwater monitoring would be completed as described in Alternative 1.
- Institutional controls would be implemented as described for Alternative 2A.

Alternative 3: Removal of Soil Exceeding MTCA C CULs, Capping, Groundwater Monitoring, and Institutional Controls

- Soil exceeding the MTCA C CULs and soil in the concrete pond area exhibiting characteristics of NAPL would be excavated, transported, and disposed of at a licensed facility. The maximum depth of excavation is 15 feet bgs. For the purposes of the cost estimate, soil from the concrete pond excavation is assumed to require treatment before landfilling at a Subtitle C disposal facility, and soil from the MTCA C CUL excavation would be disposed of at the Aragonite incineration facility. Profile analysis would determine the final disposal location. Excavations would be backfilled with clean backfill from an off-site source.
- Cells 1 and 2 would be capped as discussed in Alternative 1.
- The existing stormwater system would be removed as described in Alternative 1.
- The SER system would operate and be decommissioned as described in Alternative 1.
- Groundwater monitoring would be completed as discussed in Alternative 1.
- Institutional controls would be implemented as described for Alternative 2A.

---

[9] During remedial design, the Port worked with Ecology to establish CAMU eligibility (see Appendix N for CAMU eligibility documentation); however, cost estimates did not assume that CAMU eligibility would be established.

Alternative 4: Excavation of SER System and Soil Exceeding CULs; Groundwater Monitoring

- Soil from 0 to 15 feet bgs that contains concentrations above Method B CULs would be removed for off-site disposal. For the purposes of the FS, one-third of the soil is assumed to be disposed of in each of the three methods: direct landfilling at a Subtitle C disposal facility, organic vapor recovery treatment and landfilling at a Subtitle C disposal facility, and disposal at an incineration facility. Excavations would be backfilled using clean backfill from an off-site source.
- Operation of the SER system would continue until Method B groundwater CULs are reached. For the purposes of the FS, a minimum of 20 years of operation is assumed to achieve CULs, based on an analysis of current system efficiencies. Additional extraction wells would be installed to reach contaminated areas not addressed by the current wellfield. Once CULs are achieved, the SER system will be demobilized.
- The existing stormwater system would be removed as described in Alternative 1.
- Groundwater monitoring would be completed at existing monitoring wells to assess effectiveness of the SER system.

7.1.2 Cell 3

Three remedial alternatives were developed for Cell 3 to meet cleanup standards. As discussed in Section 4.3.1, interim actions (based on Alternative 2 [MFA, 2010c]) were completed in Cell 3 in 2010 and 2011. The FS alternatives are summarized below for completeness.

Alternative 1: Capping, Institutional Controls, and Groundwater Monitoring

- Cell 3 would be capped with a minimum of 2 feet of soil and a geotextile (i.e., a permeable cap) or an equivalent exposure barrier (e.g., liner, asphalt, concrete, building).
- Institutional controls will be implemented as part of the remedial action. These will be in the form of a restrictive environmental covenant to prohibit groundwater use and will require adherence to an SMP for protection and maintenance of surface capping and management of residual contaminated soils during redevelopment or subsurface work. Via institutional controls, ingestion of drinking water will become an incomplete pathway.
- Groundwater monitoring will be conducted at the conditional POC to demonstrate that concentrations are not increasing in groundwater. The groundwater monitoring locations and analytes are assumed to be MW-46S for arsenic; MW-45D for PCP; and MW-29D, MW-45D, MW-46D, and MW-47D for PCE.

Alternative 2: Soil Removal to RELs, Capping, Institutional Controls, and Groundwater Monitoring

- Soil exceeding the RELs would be excavated and disposed of off site. Application of the RELs, based on MTCA C CULs for industrial land use, does not indicate that potential receptors are solely industrial users. RELs are applied in Alternative 2 to identify areas for removal that exceed less conservative criteria based on an industrial worker receptor. The alternative still meets the cleanup standards for unrestricted land use through capping and institutional controls.
- Cell 3 would be capped as discussed in Alternative 1.
- Institutional controls would be implemented as part of the remedial action, as with Alternative 1.
- Groundwater monitoring would be implemented as discussed in Alternative 1.

Alternative 3: Soil Remediation to CULs and Groundwater Recovery/Treatment

- Soil with concentrations above the Method B direct-contact CULs would be excavated, transported, and disposed of off site at a licensed facility. Excavated soil with IHS concentrations below CULs (i.e., clean overburden soil) and oversized inert material would be temporarily stockpiled on site and used as excavation backfill. Clean, imported fill would be used to backfill excavations.
- Groundwater containing concentrations above Method B groundwater CULs would be extracted, treated, and discharged at an existing stormwater outfall. Groundwater monitoring would also be completed to assess the groundwater extraction system performance.
- No institutional controls would be required following operation of the treatment system and soil removal. Existing controls would be continued during remediation (e.g., restricting access to the LRIS and restricting the use of groundwater).

7.1.3 Cell 4

Three remedial alternatives were developed for Cell 4 to meet cleanup standards. As discussed in Section 4.3.2, interim actions based on Alternative 2 were completed in Cell 4 in 2010 and 2011. The alternatives for Cell 4 include only actions for soil because IHSs were not detected in groundwater above the CULs. The FS alternatives are summarized below for completeness.

Alternative 1: Engineered Cap and Institutional Controls

Alternative 1 blocks exposure pathways via capping and institutional controls:

- Cell 4 would be capped with an exposure barrier (e.g., soil, liner, asphalt, concrete, a building), concurrent with the cap profiles outlined in the TEE (MFA, 2010c). The estimated cap surface area is 7.5 acres.
- Institutional controls would be implemented as part of the remedial action. These would be in the form of a restrictive environmental covenant to require cap maintenance and adherence to an SMP for protection and maintenance of surface capping and management of residual contaminated soils. The restrictive covenant would also prohibit use of groundwater on Cell 4, preventing installation of any water well that may influence groundwater flow and pull contamination from Cell 2 toward Cell 4.

Alternative 2: Engineered Cap, Removal of Soil above RELs, and Institutional Controls

Alternative 2 blocks exposure pathways via capping, excavation of areas exceeding preliminary RELs, and institutional controls:

- An engineered cap, identical to the cap described in Alternative 1, would be placed on Cell 4.
- Soil exceeding the preliminary RELs would be excavated and managed according to an SMP. For the purposes of the cost estimate, soil is assumed to be removed for off-site disposal at a Subtitle C facility. Application of the preliminary RELs, based on MTCA C CULs for industrial land use, does not indicate that potential receptors are solely industrial users. Preliminary RELs are applied in Alternative 2 to identify areas for removal that exceed less conservative criteria based on an industrial worker receptor. The alternative still meets the cleanup standards for unrestricted land use through capping and institutional controls.
- Institutional controls would be implemented as described for Alternative 1.

Alternative 3: Soil Removal to CULs

Alternative 3 eliminates exposure pathways in Cell 4 via excavation of soil exceeding CULs:

- Soil exceeding the Method B soil CULs would be excavated for off-site disposal at a licensed facility. For the purposes of the cost estimate, a total of 29,100 CY would be removed from Cell 4.
- Institutional controls would be implemented as part of the remedial action to limit the use of groundwater. Because no residual contaminated soil is expected in Cell 4 following excavation, there is no requirement for a restrictive environmental covenant regarding the soils.

7.2 Alternative Analysis

This section evaluates the proposed cleanup action alternatives in the context of MTCA requirements.

7.2.1 Threshold Requirements

The cleanup action must meet the threshold requirements, which include the following:

- Protection of human health and the environment
- Compliance with cleanup standards
- Compliance with applicable state and federal laws
- Providing for compliance monitoring

All alternatives in Section 7.1 meet the threshold requirements.

The alternatives are next evaluated against public concerns and permanent solutions through the disproportionate cost analysis (DCA) and the time frame for restoration.

7.2.2 Disproportionate Cost Analysis

The cleanup action alternative chosen would be conducted under MTCA (WAC 173-340) and would be consistent with all applicable state and federal laws. The Cells 1 and 2 RI/FS (MFA, 2011a), Cell 3 FS (MFA, 2011c), and Cell 4 RI/FS (MFA, 2010e) discuss compliance with ARARs.

Compliance monitoring for all alternatives in Section 7.1 would include construction performance criteria, a cap maintenance program, and confirmation sampling during excavation, if warranted.

Costs are determined to be disproportionate to benefits if the incremental cost of a more expensive alternative over that of a lower-cost alternative exceeds the incremental degree of benefits achieved by the more expensive alternative. As outlined in WAC 173-340-360(3)(e) and (f), DCA includes evaluation criteria that are a mix of qualitative and quantitative factors, including:

- Protectiveness
- Permanence
- Long-term effectiveness
- Management of short-term risks
- Technical and administrative implementability
- Consideration of public concerns
- Cost

Primary assumptions, unit costs, and number of units for all significant project elements are included in the FSs for Cells 1 and 2, Cell 3, and Cell 4. Net present value calculations are also included for operation, maintenance, and monitoring costs, if applicable. Summaries of the analyses are provided in the three RI/FSs.

7.2.2.1 Cells 1 and 2

Alternatives 1, 2, 3, and 4 meet the threshold criteria and were included in the DCA. The estimated net present value costs for implementation, operation and maintenance, and monitoring are as follows:

Alternative 1:	$7,030,000
Alternative 2A:	$10,301,000
Alternative 2B:	$10,320,000
Alternative 3:	$32,883,000
Alternative 4:	$367,531,000

Alternative 1 costs less than Alternatives 2A and 2B. Alternatives 2A and 2B are estimated to be one-third the cost of Alternative 3. Given the large cost discrepancy and the limited incremental benefit over the other alternatives, the baseline option, Alternative 4, is disproportionately costly and is rejected as an alternative. Based on this assessment, Alternatives 1, 2A, and 2B remain viable options in terms of cost effectiveness. Alternative 2B, for an incremental cost of approximately $3.3 million over Alternative 1, provides a greater degree of protectiveness and long-term effectiveness. In addition, if material removed is CAMU-eligible, it is estimated that Alternatives 2A and 2B will cost approximately $1.7 million less.

7.2.2.2 Cell 3

Excluding the cost criterion, the relative ratings reflected in Table 6-1 of the Cell 3 FS show that Alternative 3 is rated the worst; Alternative 1 is rated next, followed by Alternative 2. Alternatives 1 through 3 meet the threshold criteria and were included in the DCA. The estimated net present value costs for implementation, operation and maintenance, and monitoring from the Cell 3 FS (MFA, 2011c) are as follows:

Alternative 1:	$1,263,000
Alternative 2:	$1,524,000
Alternative 3:	$22,880,000

The estimated cost for Alternative 3 is $21,356,000 greater than Alternative 2. Given the large cost discrepancy and the limited incremental benefit over Alternative 2, Alternative 3 is disproportionately costly and is rejected as an alternative. Based on this assessment, Alternative 2 remains a viable option. The estimated cost for Alternative 2 is $261,000 greater than Alternative 1, but for the incremental cost difference, Alternative 2 was determined to provide a greater degree of protectiveness and long-term effectiveness.

7.2.2.3 Cell 4

Alternatives 1 through 3 meet the threshold criteria and were included in the DCA. The estimated net present value costs for implementation, operation and maintenance, and monitoring from the Cell 4 FS (MFA, 2010e) are as follows:

- Alternative 1: $707,000
- Alternative 2: $720,000
- Alternative 3: $12,692,000

Given the large cost discrepancy and the limited incremental benefit over the other alternatives, the baseline option, Alternative 3, is disproportionately costly and is rejected as an alternative. Alternative 1 costs slightly less than Alternative 2. Based on this assessment, Alternatives 1 and 2 remain viable options in terms of cost effectiveness. Alternative 2, for an incremental cost of $13,000 over Alternative 1, provides a greater degree of protectiveness and long-term effectiveness.

7.2.3 Provide for Reasonable Restoration Time Frame

WAC 173-340-360(4) contains guidance for determining reasonable restoration time frames. A preference is given for alternatives that can be implemented in less time if other factors such as permanence and costs are equal.

7.2.3.1 Cells 1 and 2

Alternatives 1, 2, and 3 likely would have a longer restoration time frame than Alternative 4 because not all soil exceeding CULs would be removed. The practicability of achieving a shorter restoration time frame is limited; Alternative 4 requires the removal of more than 500,000 tons of soil, decreasing the practicability of such an option.

To achieve site restoration in the soil POC (within 15 feet of the ground surface), Alternatives 1, 2, and 3 include natural attenuation of IHSs. Alternatives 1, 2, and 3 do not rely on natural attenuation to protect receptors, but instead use engineering and institutional controls to address risks to human health and the environment and to restore the LRIS to potential future uses. The effectiveness and reliability of institutional controls at the LRIS are high because of the Port's continued ownership and management of the LRIS. Long-term cap monitoring and maintenance are included as part of Alternatives 1, 2, and 3 to control and monitor hazardous substances at the LRIS.

7.2.3.2 Cell 3

Alternative 2 has a slightly greater degree of permanence than Alternative 1; however, Alternative 1 costs less than Alternative 2. Alternative 1 can be implemented within a shorter time frame than Alternative 2.

As discussed in the RI report, chemicals in groundwater likely are stable or declining over time; therefore, soil with IHS concentrations above CULs that would remain in Alternatives 1 and 2 is not likely to leach into groundwater. For Alternatives 1 and 2, protection of human health and the environment against risks associated with soil contaminants remaining after excavation would be achieved through institutional controls rather than through meeting cleanup standards. These protections can be established within a reasonably short time frame.

7.2.3.3 Cell 4

Alternatives 1 and 2 likely would have a longer restoration time frame than Alternative 3 because soil exceeding CULs would not be removed. The practicability of achieving a shorter restoration time frame is limited; Alternative 3 requires the removal of more than 42,000 tons of soil, decreasing the practicability of such an option.

To achieve site restoration in the soil POC (within 15 feet of the ground surface), Alternatives 1 and 2 include natural attenuation of IHSs. Alternatives 1 and 2 do not rely on natural attenuation, but instead use engineering and institutional controls to address risks to human health and the environment and to restore the LRIS to potential future uses. The effectiveness and reliability of institutional controls at the LRIS are high because of the Port's continued ownership and management of the LRIS. Long-term cap monitoring and maintenance are included as part of both Alternatives 1 and 2 to control and monitor hazardous substances at the LRIS.

7.2.4 Expectations for Alternatives

WAC 173-340-370 outlines Ecology's expectations for the development of alternatives and the selection of cleanup actions. There is some flexibility in the expectations, but generally Ecology expects the treatment of the following: liquid wastes, high concentrations of hazardous substances, highly mobile hazardous materials, and discrete areas of hazardous materials that lend themselves to treatment.

Ecology also favors the minimization of long-term management for small sites through the use of destruction, detoxification, and/or removal to bring concentrations on site to below CULs. It recognizes the need to use engineering controls, such as containment, for sites where there are large volumes of low-level contamination and where treatment is impractical. Ecology also expects that measures will be taken to avoid stormwater contamination and potential migration off site. There is a preference for consolidation of hazardous substances left on site in order to minimize potential for direct contact and migration.

Contamination of surface water near the LRIS should also be avoided through the control of runoff and groundwater discharge or migration. Ecology acknowledges that natural attenuation may be appropriate where criteria are met. It also expects that any cleanup actions chosen with consideration given to WAC 173-340-370 will not result in a significantly greater overall threat to human health and the environment than other alternatives.

The provided cleanup action alternatives were designed to meet Ecology's expectations.

8 FEASIBILITY ANALYSIS: PORT-OWNED PROPERTIES

The Port-owned properties are part of the upland off-property adjacent to the LRIS at 111 West Division Street in Ridgefield, Washington (see Figure 1-2).[10] The Port-owned properties comprise the Port Railroad Avenue properties (east of the LRIS), the Port marina property (south of the LRIS), and the Port proposed overpass property (south of the LRIS). The feasibility analysis conducted is consistent with the analysis conducted for the LRIS (see Section 7). See Section 2.2.2 of this report for further background information on this area.

8.1 Technology Screen

Consistent with WAC 173-340-350(8)(b)—Screening of Alternatives, individual cleanup action components (technologies) were reviewed and screened to identify applicable methods for remediating the soil on the Port-owned properties. A preliminary screening of applicable technologies was completed, based on technologies discussed in the Federal Remediation Technologies Roundtable screening matrix (FRTR, 2008), as well as on other commonly used remediation methods. Effectiveness and implementability of the technologies were assessed for the specific contaminants in the soil, resulting in a list of technologies that were retained for further consideration (see Appendix O, Table O-1).

8.2 Alternatives

Remedial alternatives for the Port-owned properties are developed using the individual cleanup technologies retained from the technology screening process discussed in Table O-1, Appendix O, with consideration of the CULs presented in Section 6. The development of remedial alternatives involves combining various remedial technologies into a comprehensive approach that accomplishes the remedial action goals.

Exposed soil on the Port marina property (located between the LRIS property boundary and the paved area of the marina property) was capped with approximately 1 foot of clean soil during interim LRIS actions (see Section 4.3), and a polypropylene geotextile fabric was placed above the native, impacted soil and below the clean layer. These actions and the presence of an asphalt cap on the rest of the Port marina property eliminate exposure to underlying soil, and therefore cleanup actions for this area were not further considered.

In the proposed Port overpass property (located south of the LRIS Cell 3 and east of McCuddy's Marina), construction of an overpass will reduce potential for exposure to soil. Construction will include covering the overpass footprint with a cap consistent with LRIS capping options. This

---

[10] Note that the FS does not consider non-Port-owned properties that are part of the upland off-property. As described in Section 6.1.2.2, further characterization and risk characterization will be conducted.

construction will eliminate exposure to underlying soil, and therefore cleanup actions for this area were not further considered.

For the Railroad Avenue properties, three remedial alternatives were developed that potentially meet cleanup standards. Alternatives were evaluated relative to ecological CULs; note that soil exceedances of ecological CULs and the preliminary human health CULs are colocated, and therefore any remedy developed for protection of ecological receptors is also expected to mitigate unacceptable risk to human health (see Section 6.1.2.1). A no-action alternative was considered and dismissed as an option because of ecological exposure concerns. The remedial alternatives are described below and are evaluated in detail in Section 8.3.

8.2.1 Alternative 1: Institutional Controls

Under Alternative 1, institutional controls would be implemented at the Railroad Avenue properties. These controls could include deed restrictions, access restrictions such as installing a fence, and signage.

8.2.2 Alternative 2: Engineered Cap

The primary components of Alternative 2 are:

- Placement of a cap at the Port Railroad Avenue properties to mitigate ecological exposure to dioxins
- Annual cap monitoring and development of an SMP and a cap maintenance plan.

Alternative 2 relies on the installation of an engineered cap over the existing grade at the Railroad Avenue properties to protect ecological receptors from exposure. For the purposes of the cost estimate, the cap consists of 2 feet minimum of gravel over a geotextile separation layer to demarcate the underlying soil. The actual cap configuration will be based on Ecology-approved cap profiles. Considering the existing topography, subgrade preparation, regrading, and construction of a retaining wall may be required to protect cap integrity. Right-of-way considerations involving the City and the Port and stormwater management requirements by the City would be incorporated into the design of Alternative 2 as well. The SMP and the cap maintenance plan would identify procedures in the event of future development or of any condition in which the protective cap is breached. Public concerns and comments would be considered by Ecology as part of the cleanup action selection process, consistent with WAC 173-340-600.

8.2.3 Alternative 3: Sampling and Soil Removal

Primary components of Alternative 3 are:

- Prefinal design sampling
- Removal of soil to CULs
- Placement of crushed rock for operational surface

A work plan would be prepared defining sampling locations and methods to supplement existing sampling data from the Railroad Avenue properties. A report documenting sampling results would be prepared for Ecology.

Based on existing sampling data and knowledge of how dioxins behave in the environment, the CSM assumes that only surface soil is impacted with dioxins above the CULs and that, for the purposes of the cost estimate, 1 foot of soil would be removed from the Port Railroad Avenue properties. Additional sampling would determine which areas of the property require soil removal and to verify the 1-foot depth assumption. For the purposes of the FS, the excavation boundary for the Railroad Avenue properties requiring soil removal is shown in Figure 8-1. Removed soil would be replaced with clean soil and/or gravel for an operational surface and to protect against erosional forces. Based on research conducted to date, the cost estimate assumes that the excavated soil would be transported by truck and disposed of as nonhazardous material at a Subtitle D landfill facility permitted to accept Railroad Avenue site soils with detected concentrations.[11]

8.3 Detailed Alternative Analysis

This section describes the process by which the preferred cleanup action alternative for the Railroad Avenue site will be selected. The MTCA requirements are used as the criteria for evaluating cleanup action alternatives. The selected cleanup action must meet the minimum threshold requirements, pursuant to WAC 173-340-360 and described below.

8.3.1 Threshold Requirements

The cleanup action must meet the MTCA threshold requirements (WAC 173-340-360(2)(a)), which include the following:

- Protection of human health and the environment
- Compliance with cleanup standards and applicable state and federal laws
- Provisions for compliance monitoring

8.3.1.1 Protection of Human Health and the Environment

Alternative 1 (Institutional Controls) is protective of both human health and the environment, as institutional controls would minimize exposure through access restrictions.

Alternative 2 (Engineered Cap) is protective of human health and the environment. Under this alternative, a cap would be placed on the Railroad Avenue properties to protect ecological receptors. The cap would effectively eliminate any human health exposure as well.

Alternative 3 (Sampling and Removal) is protective of human health and the environment. This alternative involves removal of impacted soil in areas with dioxin concentrations above the CUL and

---

[11] The source of the dioxins in off-property soil is not well established. See Appendix P for waste designation information.

replacing it with clean soil. Through excavation, direct or indirect contact and exposure would be prevented for the long term.

8.3.1.2 Compliance with Cleanup Standards

This cleanup action is being conducted under MTCA (WAC 173-340). All cleanup alternatives will be conducted consistent with applicable state and federal laws, as discussed in Appendix Q.

8.3.1.3 Provision for Compliance Monitoring

Compliance monitoring, as required by WAC 173-340-410 and 173-340-720 through 173-340-760, consists of protection monitoring, performance monitoring, and confirmation monitoring to determine short- and long-term safety and effectiveness of the implemented alternative.

Protection monitoring is used to confirm that human health and the environment are adequately protected during construction, operation, and maintenance periods. Performance monitoring confirms that the cleanup action has attained cleanup standards or other performance standards, including those outlined in any permits. Confirmation monitoring may be included to verify the long-term effectiveness of the remedial action.

Alternative 1 (Institutional Controls) relies on existing data to address compliance monitoring requirements.

Alternative 2 (Engineered Cap) makes use of existing data to document soil quality. Confirmation, performance, and protection monitoring would all take place as part of construction oversight during the implementation of the Railroad Avenue properties cap as well as the post-implementation cap monitoring program.

Alternative 3 (Sampling and Removal) includes additional sampling activities, including protection, performance, and confirmation monitoring. Protection monitoring would consist of engineering oversight to verify safe material handling procedures, effective health and safety measures, and dust monitoring. Engineering controls would be applied as necessary to protect nearby residences from exposure and unsafe conditions. Performance monitoring in the form of confirmation sampling would be conducted at the Site by obtaining composite samples before replacing soil.

8.3.2 Disproportionate Cost Analysis

Costs are determined to be disproportionate to benefits if the incremental cost of a more expensive alternative over that of a lower-cost alternative exceeds the incremental degree of benefits achieved by the more expensive alternative. As outlined in WAC 173-340-360(3)(e) and (f), DCA includes evaluation criteria that are a mix of qualitative and quantitative factors, including protectiveness, permanence, long-term effectiveness, management of short-term risks, technical and administrative implementability, consideration of public concerns, and cost. A summary of the analysis is provided in Table 8-1.

Alternatives 1, 2, and 3 were included in the DCA.

Protectiveness

Overall protectiveness of human health and the environment includes the degree to which existing risks are reduced, time required to reduce risk at the facility and attain cleanup standards, on-site and off-site risks resulting from implementing the cleanup action alternative, and improvement of the overall environmental quality. All three alternatives are protective at the $1\text{x}10^{-5}$ cumulative risk level applied to the LRIS and are protective of ecological receptors. Alternatives 2 (Engineered Cap) and 3 (Sampling and Removal) provide additional measures in comparison to Alternative 1 (Institutional Controls) to enhance protectiveness for all areas exceeding the CUL. Alternative 1 would be selected only if the current contaminant concentrations were found to be consistent with developing Ecology regulatory updates on risk management of dioxins in urban soils. Alternative 2 is more protective, as the placement of a soil cap would provide effective measures to eliminate soil exposures. Alternative 3 is the most protective of the three remedies, as areas of soil exceeding the CUL are removed from the Railroad Avenue properties for off-site disposal. Alternative 3 receives a slightly higher scoring than Alternative 2 to reflect the reduction in area and volume of soils exceeding the CUL.

Permanence

Permanence is a factor by which the cleanup action alternative permanently reduces the toxicity, mobility, or volume of hazardous substances. The adequacy of the alternative in destroying the hazardous substances, the reduction or elimination of hazardous substance releases and sources of releases, the degree of irreversibility of the waste-treatment process, and the characteristics and quantity of treatment residuals generated are all considered under this criterion.

MTCA states that when selecting an alternative, preference shall be given to “permanent solutions to the maximum extent practicable.” A “permanent solution” is defined in WAC 173-340-200 as a cleanup action in which the cleanup standards of WAC 173-340-700 through 760 are met without further action being required at the site being cleaned up or at any other site involved with the cleanup action, other than the approved disposal of any residue from the treatment of hazardous substances.

Alternative 1 (Institutional Controls) has the lowest level of permanence. Institutional controls would not serve to destroy the substances; however, if effectively implemented, they could reduce the human or ecological exposure. No additional actions, including treatment, would be conducted on the Site.

Alternative 2 (Engineered Cap) has a higher level of permanence, given that a cap will contain the dioxins. The cap does not destroy the substances, but does effectively reduce the mobility and eliminate exposure. Breaching the cap would require a significant effort or natural event.

Alternative 3 (Sampling and Removal) has the highest level of permanence. Soil exceeding the CULs is removed.

Effectiveness over the Long Term

Long-term effectiveness includes the degree of certainty that the alternative will be successful; the reliability of the alternative for the period of time during which hazardous substances are expected to remain on site at concentrations that exceed CULs; the magnitude of residual risk with the alternative in place; and the effectiveness of controls required to manage treatment residues or remaining wastes.

Alternative 1 (Institutional Controls) is less effective. Properly implemented, institutional controls have been found to be effective in protecting receptors. To achieve long-term effectiveness, the institutional controls placed must be maintained periodically and renewed or reevaluated. No further action would be conducted to address soils exceeding the CUL in the Railroad Avenue properties.

Alternative 2 (Engineered Cap) provides for long-term effectiveness through the use of capping in the Railroad Avenue properties. The cap provides effective long-term protection for ecological receptors and eliminates exposure to nearby residents.

Alternative 3 (Sampling and Removal) provides improved long-term effectiveness because soil will be permanently removed, resulting in a marked reduction in the area and volume of soils exceeding the CUL.

Management of Short-Term Risks

Management of short-term risks addresses the risk to human health and the environment associated with the alternative during construction and implementation, and the effectiveness of measures that will be taken to manage such risks. Short-term risks to remediation workers, the general public, and the environment are assessed under this criterion. Generally, short-term risks are expected to be linearly related to the amount of material handled, treated, and/or transported/disposed of (e.g., worker injury/CY excavated [equipment failure], public exposure/CY per mile transported [highway accident], release to environment/gallons treated [treatment system upset]).

Alternatives 1 (Institutional Controls) and 2 (Engineered Cap) rate high for management of short-term risks. These alternatives do not involve significant handling or management of impacted soil and, because of the low probability of disturbing soil associated with cap placement, will not result in excess dust or high risk for exposure during construction.

Alternative 3 (Sampling and Removal) rates lower for short-term risk. This alternative involves construction to remove impacted soil. This construction will disturb soil, increasing the potential for improper handling during the removal process, and may result in the generation of dust that could transport the contaminant and become an inhalation exposure. Most of the construction associated with Alternative 3 would take place in a location adjacent to private residences. Construction equipment can be dangerous if operated improperly or if the public enters work areas. Alternative 3 increases the likelihood of conflicts between the general public and construction activities.

Technical and Administrative Implementability

Technical and administrative implementability addresses the ability to implement the alternative and includes consideration of whether the alternative is technically possible; the availability of necessary off-site facilities, services, and materials; administrative and regulatory requirements; scheduling; size; complexity; monitoring requirements; access for construction operations and monitoring; and integration with existing facility (or locally applicable) operations and other current or potential remedial actions.

All three alternatives are implementable from a technical and administrative standpoint. Alternative 1 (Institutional Controls) will require significant administrative effort to ensure that institutional controls are implemented correctly and remain effective. Alternative 3 (Sampling and Removal) will require increased coordination with area property owners to accomplish the remediation work.

Consideration of Public Concerns

Consideration of public concerns addresses concerns from individuals, community groups, local governments, tribes, federal and state agencies, and any other organization that may have an interest in or knowledge of the Site and that may have a preferred alternative.

Ecology and the Port have addressed community concerns throughout the history of this project. Additional issues or concerns will be considered by Ecology as part of the cleanup action selection process, consistent with WAC 173-340-600. Public comments on the project and this document will be solicited from the community during the formal comment period, following Ecology input. Common community concerns include noise and traffic, short- and long-term risks, and the time frame of any proposed cleanup actions. Community concerns will also be factored into local permit processes, including responding to any City permitting concerns.

All of the alternatives would benefit from previous outreach actions (distribution of fact sheets to public and a community meeting on February 12, 2012) for addressing potential community concerns that could arise because of the presence of dioxins above the CUL in off-property areas. In addition, Ecology will ensure that any cleanup action selected accounts for further community input (i.e., public comment), consistent with WAC 173-340-600.

Alternatives 2 (Engineered Cap) and 3 (Sampling and Removal) likely would include concerns relating to required construction activities, noise, property owner disturbance, and related actions, with Alternative 3 having the greatest impact to the surrounding community because of the disturbance of contaminated soil. These types of concerns were raised during previous site construction activities. The performance of construction work near private properties likely would result in a significant degree of concern from affected property owners. Such concerns would be managed throughout the project as part of a preconstruction community outreach effort.

Cost

The detailed cost estimates for Alternatives 1 through 3 are provided in Appendix R, Tables R-2, R-3, and R-4, respectively. Primary assumptions, unit costs, and number of units for all significant project elements are included. The estimated costs (2013 cost basis) for implementation, operation and maintenance, and monitoring are as follows:

Alternative 1:	$53,000
Alternative 2:	$184,000
Alternative 3:	$297,000

Alternative 3 is the most expensive of the alternatives. The alternative is incrementally more expensive than Alternative 2, while providing only modest improvements in protectiveness and permanence. Alternative 1 has the lowest cost, but the alternative does not provide the same degree of risk management and places constraints on a property adjacent to residential properties that could otherwise be a useful asset to the community.

8.3.3 Provide for Reasonable Restoration Time Frame

WAC 173-340-360(4) contains guidance for determining reasonable restoration time frames. Consideration is required for potential risks posed by the Site to human health and the environment; the practicability of achieving a shorter restoration time frame; current use of the Site, surrounding areas, and associated resources that are, or that may be, affected by releases from the Site; availability of alternative water supplies; likely effectiveness and reliability of institutional controls; ability to control and monitor migration of hazardous substances from the Site; toxicity of the hazardous substances at the Site; and the natural processes that reduce concentrations of hazardous substances and that have been documented to occur at the Site or under similar conditions.

All of the alternatives possess reasonable restoration time frames. Alternative 3 involves more extensive construction activities and will require the most time to complete. The engineered cap (associated with Alternative 2) and implementation of institutional controls (associated with Alternative 1) can be implemented readily. Institutional controls can be effective and reliable if implemented correctly and maintained.

8.3.4 Expectations for Alternatives

WAC 173-340-370 outlines Ecology's expectations for the development of alternatives and the selection of cleanup actions. Based on the above DCA, Alternative 2 is emphasized as the most likely to ensure compliance with the expectations. Each of the expectation criteria is summarized below:

Treatment of Waste and Hazardous Substances

Ecology generally expects the treatment of liquid wastes, high concentrations of hazardous substances, highly mobile hazardous materials, and discrete areas of hazardous materials that lend themselves to treatment. There are no liquid wastes on the Railroad Avenue properties. The concentrations are not especially high and, in fact, correspond at most to a 1 in 100,000 excess cancer risk level and are less than an order of magnitude above CULs. Further, the contaminants on the Railroad Avenue properties are not highly mobile.

All alternatives comply with Ecology's expectation.

Minimization of Long-Term Management at Small Sites

Ecology also favors the minimization of long-term management for small sites through the use of destruction, detoxification, and/or removal to bring concentrations on site to below CULs.

Alternative 3 involves removal; however, destruction and detoxification of dioxins are not feasible. Alternative 1 would require active long-term management of the Site to ensure that institutional controls remain effective. Alternative 2 requires long-term management of the cap.

Use of Engineering Controls at Large Sites

Ecology recognizes the need to use engineering controls, such as containment, for sites where there are large volumes of low-level contamination and where treatment is impractical.

The Railroad Avenue properties do not include a large volume of soil; however, the soil that is in place on the property would be categorized as low-level contamination. The use of capping and on-site management under Alternative 2 is consistent with Ecology expectations.

Minimize Stormwater Contamination and Off-Site Migration; Control Runoff to Avoid Surface Water Contamination

Ecology also expects that measures will be taken to avoid stormwater contamination and subsequent migration off site. In addition, contamination of surface water near the off-property should be avoided through the control of runoff and groundwater discharge or migration.

Because the contaminants have limited mobility, stormwater contamination will be minimized. In addition, the design may minimize run-on from the street to minimize the amount of stormwater that enters the area.

Minimize Direct Contact and Migration by Consolidating Hazardous Substances

Ecology expects that when hazardous substances remain on site at concentrations that exceed CULs, those hazardous substances will be consolidated to the maximum extent practicable where needed to minimize the potential for direct contact and migration of hazardous substances.

No consolidation is considered appropriate or practicable under Alternative 2, as the area to be addressed is relatively compact.

Control Groundwater Discharge or Migration to Avoid Surface Water Contamination

Groundwater is not a consideration on the off-property, as the contamination is surficial and the water table is greatly removed from the contaminated layer.

This criterion is not applicable to the Railroad Avenue property.

Use of Natural Attenuation

Ecology acknowledges that natural attenuation may be appropriate where criteria are met.

Although Alternatives 1 and 2 do not rely on natural attenuation, or degradation of dioxins, some reduction in concentrations may occur over the long term because of natural processes.

Significantly Greater Overall Threat to Human Health and the Environment as Compared to Other Alternatives

Ecology expects that any cleanup actions chosen with consideration of WAC 173-340-370 will not result in a significantly greater overall threat to human health and the environment than with other alternatives. All alternatives will minimize threats to human health and the environment during the remedial actions, as long as they are successfully implemented.

9 FEASIBILITY ANALYSIS: LAKE RIVER

Lake River is a side channel of the Columbia River and lies within the lower Columbia River west of Ridgefield, Washington, near the confluence of the Columbia and Willamette rivers. The Lake River remediation area described in this FS report consists of the shoreline adjacent to the LRIS, approximately 2 miles upstream from where Lake River meets the Columbia River. See Section 2.2.3 of this report for further background information on this area.

9.1 Technology Screen

Consistent with the SMS requirements in WAC 173-204-560(4)(f)(iii) and using MTCA procedures as a guideline (WAC 173-340-350(8)(b)—Screening of Alternatives), individual cleanup action components (technologies) were reviewed and screened to identify applicable methods for remediating the impacted sediment in Lake River. The preliminary screening of applicable technologies was completed based on technologies identified in the FRTR (2008), as well as other commonly used remediation methods. Effectiveness and implementability of each technology were assessed for the specific contaminants in the sediment, resulting in a list of technologies that were retained for further consideration (see Table O-2, Appendix O).

9.2 Alternatives

Remedial alternatives for Lake River were developed by using the individual cleanup technologies retained from the technology screening process discussed in Table O-2, Appendix O, and by considering the preliminary CULs presented in Section 6. The selected CUL is 5 ng/kg dioxin TEQ. The number and magnitude of dioxin CUL exceedances far exceed those of other chemicals that exceeded screening criteria, as described in Section 3. Therefore, only dioxins were selected as IHSs, and any of the remedial options presented here and designed to meet the selected CUL are expected to remedy other contaminants as well. Individual remedial technologies have been assembled into a comprehensive approach that will achieve the remedial action goals for impacted sediment.

Four remedial alternatives have been developed for Lake River that potentially meet cleanup standards. A no-action alternative was considered but was dismissed from further evaluation, as it does not meet cleanup standards.

Interim actions for upland soil that is supported by the riverbank have been completed (Cell 3) or will be completed in 2013 (Cell 2) (see Section 4). For all of the alternatives in this analysis, the area between the upland cap and the chosen in-water remedy (approximately elevation +11 [Columbia River Datum] down to the slope break to the beach) will be covered with a geotextile filter fabric and stabilized with rock armor. Armoring of the bank will reinforce the existing slopes and act as a physical barrier to the movement of underlying soil and sediment. No other remedial alternatives for the riverbank were retained from the technology screen because of the discovery of cultural artifacts in the bank and the requirement to preserve the artifacts in place (see Appendix O).

The remedial alternatives are described below and are evaluated in detail in Section 9.3.

9.2.1 Alternative 1: Monitored Natural Recovery

The primary components of Alternative 1 are:

- Bank stabilization
- Natural attenuation
- Long-term monitoring program
- Institutional controls

Alternative 1 relies on stabilization of the riverbank, combined with the natural deposition of clean sediment over impacted sediment in Lake River, to engender natural attenuation in the form of dilution of contaminant concentration through mixing and/or a physical barrier (if no mixing occurs) that acts to reduce the mobility, volume, and concentration of contaminants in sediment. This process occurs under favorable conditions over an indeterminate period of time and acts without human intervention.

A comprehensive work plan would be prepared outlining monitoring techniques; methods for further characterization of the Lake River fluvial conditions; and sampling events to better understand the deposition rates of fluvial process that would affect natural attenuation. The plan would define sampling locations and methods to supplement existing sampling data from within the study area perimeter.

Following the in-depth characterization of the fluvial environment, institutional controls (e.g., no-anchor zones) and/or a monitoring program would be developed that would be capable of verifying the ongoing effectiveness of recovery by natural processes. The monitoring program would quantify the extent of risk reduction achieved.

9.2.2 Alternative 2: Enhanced Monitored Natural Recovery

Primary components of Alternative 2 are:

- Bank stabilization
- Placement of a sand layer to enhance natural attenuation

- Long-term monitoring plan
- Institutional controls

Alternative 2 relies on a combination of bank stabilization, enhanced natural recovery (ENR), and a long-term monitoring program to protect receptors and verify recovery, resulting in enhanced monitored natural recovery (EMNR) of Lake River. EMNR is accomplished by placing a layer (approximately 6 to 12 inches) of clean sand over the impacted sediment and then monitoring the additional natural recovery that occurs. The ENR layer would not be intended to completely isolate the impacted sediment as in a conventional sediment capping alternative but instead would jump-start the natural deposition of clean sediment over impacted sediment. This layer would provide a surface stratum of cleaner sediment, resulting in an immediate reduction in surface contaminant concentrations. Biological and wave-induced mixing would further enhance dilution of contaminant concentrations in existing sediment. Should no further mixing occur, the ENR layer would act to accelerate the process of physical isolation that would continue over time through natural sediment deposition. These processes reduce the mobility, volume, and concentration of contaminants in surface sediment.

A thin layer of sand for ENR may be placed by clamshell spreading or other contractor-proposed means. Sand for ENR would be placed over all areas with preremediation dioxin concentrations in surface sediment greater than the CUL of 5 ng/kg dioxin TEQ (see Figure 6-2 for sample locations exceeding the CUL).

As in Alternative 1, a comprehensive work plan would be prepared, outlining characterization of the fluvial conditions at Lake River; monitoring techniques; and sampling events. In addition, institutional controls (e.g., no-anchor zones) and/or a long-term monitoring program would be developed that would be capable of verifying the ongoing effectiveness of recovery by natural processes.

9.2.3 Alternative 3: Engineered Cap

Primary components of Alternative 3 are:

- Bank stabilization
- Placement of an engineered sand cap
- Placement of a protective armor layer
- Long-term monitoring and maintenance
- Institutional controls

Alternative 3 implements engineering and institutional controls to prevent the migration of and exposure to sediment containing contaminants at concentrations exceeding the site-specific CUL at Lake River. Under Alternative 3, bank stabilization would be performed and an engineered 2-foot sediment cap would be placed by mechanical means over the designated remediation area (i.e., areas exceeding the dioxin CUL). Appropriate options for the capping material would be developed in detail during the remedial design.

Impacts to active federal navigation channels designated by the COE are subject to review by the COE and the U.S. Coast Guard. Typically, where capping is performed within the limits of an active federal navigation channel, the cap's top elevation is maintained below the project depth, with sufficient clearance to provide for channel maintenance dredging. Pending further review of channel dimensions and navigation requirements, the cost for removal of sediment from within the navigation channel project boundary has not been included in Alternative 3.

The cap material would be placed in a manner that minimizes mixing of impacted sediment and cap material, allows for proper settlement during and after construction, and minimizes the amount of turbidity generated in the water column. Following the placement of the engineered cap, a protective layer of rock armor would be placed to protect against erosion of the underlying sediment cap.

Cap integrity would be managed on an ongoing basis through implementation of a monitoring and maintenance program, which would include a plan outlining the requirements for routine cap performance monitoring, schedule, emergency response, and reporting. It would also include steps to be taken if the cap fails to meet the performance criteria.

Restrictions on future maintenance dredging would be required as an institutional control in order to prevent breaching of the engineered sediment cap without appropriate remedial measures. Additional restrictions on navigation, access to shore, and short-term future land use (e.g., in-water construction) would all be included as institutional controls.

9.2.4 Alternative 4: Dredging and ENR

Primary components of Alternative 4 are:

- Removal of impacted sediment through mechanical dredging
- Existing in-water structure removal
- Bank stabilization
- Placement of an ENR layer
- Monitoring natural recovery

Alternative 4 consists of removing impacted sediment in Lake River through the process of mechanical dredging. An evaluation of potential dredge scenarios (based on various potential RELs) is provided as Appendix S. The most permanent scenarios of removing all sediment with dioxin impacts above the CUL or above two times the CUL were considered (see Appendix S) but were eliminated from further analysis because of the significant remedy cost increase when compared to the limited areawide reduction in dioxin concentrations. Further, as explained in Appendix S, it is significantly less feasible to remove dioxins at such low levels because of the generation of residuals.

The scenario selected for Alternative 4 is Scenario C (removal of sediment with dioxin TEQs above 30 ng/kg). The dredge volume associated with removing sediment above an REL of 30 ng/kg dioxin TEQ is selected for purposes of the FS, and sampling conducted in the design phase will be used to further refine the dredge prism. The recommended dredge scenario involves removal of sediment with concentrations above the REL and placement of a 1-foot-thick sand layer over areas with sediment concentrations between the CUL of 5 and 30 ng/kg dioxin TEQ. This scenario results in several positive outcomes, including: (1) the maximum technically feasible reduction in dioxin concentrations is achieved, (2) all significantly impacted sediment along the LRIS shoreline is removed, and (3) other contaminants above screening levels (see Section 3) are removed. Figure 9-1 shows the estimated lateral and vertical extent of dredging and the resulting estimated surface post-dredge dioxin TEQ surrounding each sample location (the areal extent of the dredge area is estimated in this FS using Thiessen polygons, but it would be refined during design). For a discussion of the dredge scenarios that were evaluated, varying dredge volumes, and estimated postremedial concentrations, see Appendix S.

Sediment containing dioxins above the REL would be removed from the river bottom and transferred, by material barge, to an upland offloading area in the LRIS adjacent to the in-water work. Initial dewatering would take place on the material barge through filtered scuppers. Further dewatering and solidification of the dredged material in the upland area would take place before landfilling.

Dredged material would be disposed of as nonhazardous material waste at a Subtitle D landfill facility. The sediment data results have been reviewed and screened for waste designation purposes; the dredged material would not be designated as either a RCRA-listed hazardous waste or a RCRA characteristic waste.

Before dredge operations, existing in-water structures would be demolished. There are few infrastructure remnants of historical LRIS river operations; however, some dolphins, pilings, a possible submerged bulkhead, and a dock (currently in operation) are located in the sediment remediation area.

Armor would be applied to the lower portions of the bank, below where the upland interim action soil cap and bank layback daylight at elevation +11 feet Columbia River Datum. The armor would be tied in to the bank layback and extend down to overlap the dredged areas and the ENR layer. The armor would also function as a cap in the transition area, protecting against exposure and erosion.

Access improvements would be necessary to accomplish the sediment remediation. These improvements include clearing and grubbing of the site vegetation to create a staging area for sediment handling. Division Street, which runs through the LRIS between Cells 2 and 3 and which is currently used as shoreline access and a boat launch, would be used to access the sediment staging area where possible cement amending and load out of dredged sediment would be conducted.

The Lake River sediment remediation area may have various site constraints during construction, as water levels throughout Lake River are very shallow, particularly at the mouth, where Lake River empties into the Columbia River. These shallow conditions may result in the need for additional dredging in the navigational channel for purposes of access. The existing data, consisting of a 2010 sounding, indicate that water levels at the start of the work window likely would allow for the mobilization of unloaded material barges and derricks through the confluence with the Columbia River and up Lake River to the LRIS. However, access at the time of construction may change because of possible ongoing deposition. Before cleanup begins, a bathymetric survey of the river confluence area will be conducted.

Best management practices for water quality would be implemented, including silt curtains for containment; dredge method; and turbidity monitoring before, during, and after construction.

A 1-foot-thick layer of clean sediment would be placed over the remediation area to enhance the natural recovery of sediment after construction. Sand for ENR would be placed over dredged areas and resulting (presumed) generated residuals, as well as over areas not dredged and with preremediation dioxin concentrations of greater than the CUL (5 ng/kg dioxin TEQ). Monitoring of the ENR layer would ensure achievement of the CUL and continued effectiveness.

Although this alternative likely would not prevent any future dredging activities for channel maintenance and other construction activities, evaluation of sediment conditions would be required before activities involving significant sediment disturbance are initiated.

9.3 Detailed Alternative Analysis

The cleanup action alternatives related to Lake River sediments were evaluated using the SMS guidelines listed in WAC 173-204-560(4)(f)(iii) A through D and described below. The SMS requires that each cleanup study plan include an evaluation of alternative cleanup actions that protect human health and the environment by eliminating, reducing, or otherwise controlling risks posed through each exposure pathway and migration route.

9.3.1 SMS Evaluation Requirements

The proposed cleanup action alternatives must be evaluated consistent with the requirements of the SMS. The SMS requirements in WAC 173-204-560(4) are worded similar to MTCA evaluation requirements, although they are structured slightly differently. The SMS lists the following evaluation criteria to assess the cleanup action alternatives that pass the initial screening (technology screen):

- Overall protection of human health and the environment
- Attainment of the cleanup standard(s) and compliance with applicable federal, state, and local laws
- Short-term effectiveness
- Long-term effectiveness

9.3.1.1 Protection of Human Health and the Environment

According to the SMS, considerations for the protection of human health and the environment include overall protectiveness of the alternative, time required to attain the cleanup standard(s), and on-site and off-site environmental impacts and risks to human health resulting from implementing the cleanup alternatives.

All four alternatives protect human health and the environment through compliance with cleanup standards, removal and capping of impacted sediment, and/or institutional controls to manage the potential for exposure to impacted sediment.

Alternative 1 (monitored natural recovery [MNR]) is somewhat protective of human health and the environment. This alternative consists of bank stabilization and subsequent monitoring of the natural recovery of sediment within the cleanup boundary, and implementation of institutional controls, including restriction on future uses, navigation, and dredging. Natural recovery in Lake River would involve the slow deposition of clean sediment on top of existing impacted sediment and the mixing of impacted sediment and clean deposition through biological activity and wave action. Implementing the components associated with Alternative 1 would eventually prevent unacceptable exposure to the impacted sediment, relying in the short term on institutional controls. Alternative 1 has few to no on-site or off-site impacts resulting from implementation, as material is not handled and exposure during implementation is limited to sampling events. Alternative 1 relies on natural processes to attenuate impacts in the sediment, resulting in an extended time frame. Therefore, there is still potential for exposure to contaminants, as well as for institutional controls to go unheeded.

Alternative 2 (EMNR) is protective, as it includes the above restrictions plus the placement of a sand layer that would result in the immediate reduction in surface contaminant concentrations. Alternative 2 has few to no on-site or off-site impacts resulting from implementation, as handling of the sediment is limited; however, this alternative has a slightly increased potential for local exposure increases over Alternative 1 during implementation. There is a slight risk for resuspension during operations; however, proper controls during placement of the ENR layer would remove this exposure potential. Implementation of Alternative 2 would prevent exposure to the sediment over the short term as well as the long term, as the process of physical isolation and concentration reduction through mixing would continue over time with natural sediment deposition. The contamination would initially be covered by clean sand but, over the long term, it is likely to mix as a result of site use or wave action, thereby exposing receptors to dioxins in the surface sediment. In addition, achievement of the CUL would demand an extended time frame relative to Alternatives 3 and 4. State and federal permitting of future projects would require the evaluation of the impacts of maintenance dredging activities, potentially requiring ENR layer placement as part of those activities to maintain protectiveness of the remedy.

Alternative 3 (Engineered Cap) is protective because it fully isolates contaminants in the sediment from the environment immediately after construction. Alternative 3 has few to no on-site or off-site impacts resulting from implementation, as handling of the sediment is limited. This alternative has a marginally increased potential for local exposure during implementation through resuspension that may occur during sand cap placement; however, proper controls during placement of the sediment cap would eliminate this potential for resuspension. The Alternative 3 sediment cap would be designed to remain in place as a physical barrier and prevent exposure to the impacted sediment over the long term because of the engineered thickness requirements of the isolation and armor layers. Controls to prevent or repair damage to the sediment cap would be required in order to increase the likelihood that the remedy will remain protective in the long term. However, loss of the sediment cap could result in re-exposure of the environment to contaminants.

Alternative 4 (Dredge and ENR) is protective, as it uses dredging and ENR to comply with the CUL. The selected dredging scenario (see Section 9.2.4 and Appendix S) is estimated to result in a surface weighted average concentration (SWAC) of 7 ng/kg dioxin TEQ following remedy implementation (see Appendix S). The estimated SWAC is marginally above the CUL of 5 ng/kg dioxin TEQ, and significantly less time would be required to achieve the CUL than for Alternatives 1 and 2. Only Lake River areas currently exceeding the CUL were included in the SWAC calculation; when results of all Lake River sampling conducted offshore of the LRIS are included, the estimated SWAC is 4 ng/kg dioxin TEQ. Therefore, aquatic receptors (including potential catch for human consumption) that use the Lake River area offshore of the LRIS are estimated to be exposed to dioxin concentrations below the CUL. As described in Appendix S, Alternative 4 is also immediately protective of ecological receptors. Alternative 4 has a higher potential for on- and off-site impacts due to handling, transport, and disposal of impacted sediments. Alternative 4 has an increased potential for local aquatic exposure during implementation through resuspension that may occur during dredging. Proper controls during dredging would limit this exposure potential.

9.3.1.2 Compliance with Cleanup Standards and Applicable Federal, State, and Local Laws

This cleanup action evaluation is being conducted under the SMS (WAC 173-204). The selected cleanup action would be conducted consistent with all applicable state and federal laws and applicable cleanup standards, as discussed in Appendix Q.

All alternatives are anticipated to meet the CUL; however, the time required to attain the CUL differs by alternative. Alternative 1 (MNR) is likely to require the most extended time frame to attain the CUL because it relies entirely on natural processes. Alternative 2 (EMNR) also relies considerably on natural processes; however, the initial placement of a clean layer of sand is expected to decrease the time frame relative to Alternative 1. Both of these alternatives would also require some time to achieve the REL. Alternative 3 (Engineered Cap) is expected to attain the CUL immediately upon completion of the remedial action. Alternative 4 (Dredge and ENR) is expected to attain the REL immediately upon completion of the remedial action and to result in sediment conditions approaching the CUL, thus requiring less time than Alternatives 1 and 2 to ultimately achieve the CUL. Further, because a significant mass of the dioxins will be permanently removed under Alternative 4, once the CUL is achieved it is less likely that concentrations will increase above the CUL as a result of transport from the impacted subsurface.

9.3.1.3 Short-Term Effectiveness

According to the SMS, analysis of the short-term effectiveness includes consideration of the protection of human health and the environment during construction and implementation of the alternative.

Alternative 1 (MNR) provides little effective protection in the short term; however, exposure potentials are also lowest, as limited bank stabilization construction activities would be conducted. Alternative 1 would take the longest to achieve overall protectiveness, as it relies on natural processes.

Alternative 2 (EMNR) has much greater short-term effectiveness than Alternative 1 because of Alternative 2's concentration reduction in the surface contaminants due to the placement of the clean sand layer. However, Alternative 2 would leave in place elevated concentrations of impacted sediments, which are expected to become mixed into the ENR layer in the future, becoming accessible to the environment. Additional construction-related exposure would be insignificant because the sand layer can be spread slowly to minimize the disturbance of the existing sediment surface.

Alternative 3 (Engineered Cap) has the greatest short-term protectiveness because a cap, engineered for longevity, would be placed and act as a physical barrier between the environment and the impacted sediment. The sediment cap would be effective immediately after its construction and would be expected to remain effective for the long term. Construction-related exposure would be minimal because the sand layer can be spread slowly to minimize the disturbance of the existing sediment surface. Dredging in the navigation channel to accommodate the sediment cap would have some short-term construction risks.

Alternative 4 (Dredge and ENR) produces the most short-term exposure because of dredging of the sediments and the subsequent handling of the dredged material, and therefore provides the least amount of short-term effectiveness. Construction methods would be actively managed to limit the spread of disturbed, impacted sediment beyond the dredge footprint.

9.3.1.4 Long-Term Effectiveness

Pursuant to the SMS, the following were considered in analyzing the alternatives for the evaluation requirements pertaining to long-term effectiveness: degree of certainty that the alternative will be successful; long-term reliability; magnitude of residual, biological, and human health risk; and effectiveness of controls for ongoing discharges and/or controls required to manage treatment residues, remaining wastes cleanup, and/or disposal site risks.

Alternative 1 (MNR) can be effective in the long term, and additional information would be collected during the preparation of the monitoring program to confirm long-term effectiveness. The attenuation would be closely monitored to confirm that recovery is occurring and that residual, human health, and ecological risk is being mitigated. No disposal site risks are associated with this alternative. Restrictions would be placed on future uses in order to protect human receptors (increasing the long-term effectiveness if the restrictions are followed), and long-term monitoring would be implemented to confirm remedy effectiveness.

Alternative 2 (EMNR) would provide long-term effectiveness in much the same way as Alternative 1. While the placement of the ENR layer increases the short-term effectiveness, it has a reduced benefit over the long term because of mixing of the ENR layer with higher concentrations below.

Alternative 3 (Engineered Cap) provides a high level of long-term effectiveness. The design of the chemical isolation layer and the armoring layer of the sediment cap would provide a high degree of certainty in this remedy's effectiveness, assuming that the cap is maintained and repaired as necessary. Sediment caps are commonly used and easily implementable, with many examples illustrating the long-term reliability and mitigation of residuals and risks to receptors. However, implementing a sediment cap places the most restrictions on future uses. Adding material to the bottom of the river would require future navigation and shore access restrictions, as well as restrictions on dredging for the purposes of navigation. Damage as a result of marine traffic contacting shallow river substrate, propeller wash, flood events, or natural processes could jeopardize long-term effectiveness of the remedy because sediment impacts would remain in place. Appropriate design would limit these disturbances to the underlying sediment. Institutional controls would communicate the limits of the armored cap boundary as well as requirements for future development in capped areas. Long-term cap monitoring would confirm remedy effectiveness. This alternative would require that future work in these areas be performed in a manner that will not conflict with the completed cap remedy.

Alternative 4 (Dredge and ENR) has the greatest long-term effectiveness. The remedy consists of removal of sediments with the highest concentrations and placement of an ENR layer to mitigate the exposure to residuals (see Appendix S). Additional reductions in contaminant concentrations likely would occur through natural processes following remedy implementation for compliance with the CUL. The alternative does not require long-term institutional controls. Dredging is common and has a relatively high degree of certainty for success, and the long-term reliability is high. Monitoring would be conducted to ensure effectiveness and evaluate the natural recovery processes. Further, the disposal site would be an operating landfill with established long-term controls in place.

9.3.2 Cleanup Time Frame

WAC 173-204-580(3) contains guidance for determining reasonable time frames for completing the cleanup actions. The cleanup action selected shall provide for a reasonable time frame for completion, based on the consideration of many of the factors addressed throughout this report as well as the following: practicability of achieving the site cleanup standards in less than ten years; current use of the Site and surrounding areas; and potential future use of the Site and surrounding areas.

Lake River poses potential risks to human health and the environment, requiring the shortest cleanup time frame practicable. Alternatives 3 and 4 provide a relatively quick cleanup time frame, followed by Alternative 2, and ultimately achieve site cleanup standards within the ten-year time frame required by the SMS WQC 173-204-580(3)(a)(ii).

Alternative 1 (MNR) relies on natural deposition and mixing to achieve site cleanup standards and likely would have a long cleanup time. Natural attenuation through sedimentation may occur within the ten-year time frame in some areas of Lake River, and a detailed fluvial evaluation would be required to provide the level of certainty required for this analysis. Institutional controls would be required under this alternative.

Alternative 2 (EMNR) uses the placement of a clean sand layer to jump-start the natural deposition and mixing described for Alternative 1. Alternative 2 may initially achieve the CUL immediately following construction, but as mixing occurs, the concentrations in surface sediment may increase and require additional time before cleanup standards are ultimately achieved through natural recovery processes. This alternative may complete cleanup within the requisite ten-year period. Institutional controls would be required under this alternative.

Alternative 3 (Engineered Cap) leaves impacted sediment in place and places a physical barrier to prevent exposure. Alternative 3 would achieve the CUL immediately after construction. Institutional controls would be required under this alternative.

Alternative 4 (Dredge and ENR) achieves the REL through dredging and ENR. Alternative 4 would achieve the CUL after some natural recovery of sediments. Although this alternative likely would not prevent any future dredging activities, evaluation of sediment conditions would be required before activities involving significant sediment disturbance are initiated.

The current use of Lake River and surrounding areas allows for implementation of all of the action alternatives. Institutional controls would be required under Alternatives 1, 2, and 3. These would not be required under Alternative 4 because the scenario does not require that sediments remain undisturbed. Potential future uses, including shoreline improvements and access, navigability and future dredging of the navigation channel, and possible marina construction, were all considered in the development of the alternatives.

9.3.3 Evaluation of Alternatives

In WAC 173-204-580(4), the SMS specifies that, in evaluating the alternatives, the net environmental effects, relative cost effectiveness, and relative technical effectiveness should be considered for the cleanup action alternatives. For the purposes of performing a comprehensive assessment, cost and technical effectiveness were evaluated together, using the MTCA DCA framework because it addresses the above SMS requirements as well as additional requirements found in WAC 173-204-560(4)(g-k).

9.3.3.1 Net Environmental Effects

This requirement includes consideration of the net environmental effects of the alternatives, including residual effects, recovery rates, and any adverse effects of cleanup construction or disposal activities.

Under Alternative 1, leaving contamination exposed over time to gradually recover naturally may result in a net environmental effect. Some construction impacts would be associated with Alternatives 2, 3, and 4, but these impacts can be minimized through appropriate project design and construction practices.

9.3.3.2 Relative Cost and Technical Effectiveness

The MTCA DCA framework was implemented to evaluate the relative costs and technical effectiveness of the sediment remediation alternatives required by the SMS. The criteria for performing the DCA can be found below. Alternatives 1, 2, 3, and 4 comply with MTCA threshold criteria and were included in the DCA.

Costs are determined to be disproportionate to benefits if the incremental cost of a more expensive alternative over that of a lower-cost alternative exceeds the incremental degree of benefits achieved by the more expensive alternative. The DCA includes evaluation criteria that are a mix of qualitative and quantitative factors, including protectiveness, permanence, long-term effectiveness, management of short-term risks, technical and administrative implementability, consideration of public concerns, and cost. A summary of the analysis is provided in Table 9-1. Detailed cost estimates are provided in Appendix R.

Protectiveness

Protectiveness of human health and the environment includes the degree to which existing risks are reduced; time required to reduce risk at the facility and attain cleanup standards; on-site and off-site risks resulting from implementing the cleanup action alternative; and improvement of the overall environmental quality.

As discussed in the evaluation requirements (see Section 9.3.1.1), Alternatives 1 through 4 are, in varying degrees, protective of human health and the environment. The alternatives were scored as described below and summarized in Table 9-1:

- Alternative 1 (MNR) scores lowest for protectiveness, as the alternative relies on long-term natural processes to develop a physical barrier and reduce contaminant concentrations, as well as on less reliable institutional controls to protect receptors in the short term.
- Alternative 2 (EMNR) scores in the middle for protectiveness because of the placement of the ENR layer, resulting in an immediate reduction of surface concentrations of contaminants; however, contaminants remain in the subsurface and may be re-exposed.
- Alternative 3 (Engineered Cap) is scored high for protectiveness. Contaminants are physically isolated from the environment, underneath a sediment cap that is armored to contain all of the material in place over the long term. There is still potential for contaminant release in the future if significant damage to the cap occurs, but the likelihood of this is small.
- Alternative 4 (Dredge and ENR) scores high for protectiveness because the remedy consists of contaminant removal, enhances natural recovery, immediately achieves the REL, and provides for monitoring to ensure compliance with the CUL following natural recovery. No institutional controls are required (see Section 9.3.2).

Permanence

Permanence is a factor by which the cleanup action alternative permanently reduces the toxicity, mobility, or volume of hazardous substances. The adequacy of the alternative in destroying the hazardous substances, the reduction or elimination of hazardous substance releases and sources of releases, the degree of irreversibility of the waste-treatment process, and the characteristics and quantity of treatment residuals generated are all considered under this criterion.

Under the MTCA DCA process, preference is given to permanent solutions to the maximum extent practicable. A "permanent solution" is defined as a cleanup action in which the cleanup standards are met without further action being required at the site being cleaned up or at any other site involved with the cleanup action, other than the approved disposal of any residue from the treatment of hazardous substances.

Alternative 1 (MNR) has the lowest level of permanence because of the uncertainty in achieving the desired result. Sediment exceeding CULs would remain in place and would be accessible to biological and human receptors in the short term. The alternative also must include continued monitoring of the deposited sediment to verify effectiveness, and must also rely on institutional controls to protect the sedimented layer from damage (i.e., scour).

Alternative 2 (EMNR) has a slightly higher level of permanence than Alternative 1, but is still at some risk from scour of the ENR layer.

Alternative 3 (Engineered Cap) scores higher under this criterion; sediment exceeding CULs would remain in place but would be capped by an isolation layer and protective armor providing a higher degree of permanence. This alternative, as with Alternatives 1 and 2, must include continued maintenance and monitoring of the cap and would rely on institutional controls to protect the cap section from damage.

Removal of sediment in Alternative 4 (Dredge and ENR) makes this alternative the most permanent. The remedy provides compliance with the REL through dredging and ENR; monitoring will ensure compliance with the CUL following natural recovery. Risks associated with scour are significantly reduced because of removal of the most impacted sediment. No institutional controls are required.

Effectiveness over the Long Term

In addition to the evaluation requirements discussed in Section 9.3.1.4, long-term effectiveness in the DCA includes the degree of certainty that the alternative will be successful; the reliability of the alternative for the period of time during which hazardous substances are expected to remain on site at concentrations that exceed CULs; the magnitude of residual risk with the alternative in place; and the effectiveness of controls required to manage treatment residues or remaining wastes.

With proper implementation, all four alternatives can be effective over the long term under this criterion; therefore, they were rated based on the degree of certainty of effectiveness.

Alternative 1 (MNR) can be effective in the long term, provided that the natural processes occur and that the institutional controls are effective. Because of the uncertainty associated with these requirements, this alternative is scored low.

Alternative 2 (EMNR) is scored in the middle, as the remedy still relies on natural processes to achieve the ultimate cleanup goal but is enhanced by the addition of a foot of clean material, effectively bolstering the success of the sedimentation process.

Alternative 3 (Engineered Cap) is scored high because a properly constructed engineered cap has a high degree of permanence. The degree of certainty of long-term effectiveness is lower than for Alternative 4 because of the potential that future damage to the cap could result in releases of contaminated sediment.

Alternative 4 (Dredge and ENR) is most effective over the long term. The remedy provides compliance with the REL through contaminant removal and ENR; monitoring will ensure compliance with the CUL following natural recovery. No institutional controls are required. This alternative is therefore rated the highest.

Management of the Short-Term Risks

As discussed in the evaluation requirements (see Section 9.3.1.3), this factor addresses the risk to human health and the environment associated with the alternative during construction and implementation, and the effectiveness of measures that would be taken to manage such risks. Short-term risks to remediation workers, the general public, and the environment are assessed under this criterion. Generally, short-term risks are expected to be linearly related to the amount of material handled, treated, and/or transported/disposed of (e.g., worker injury/CY dredged [equipment failure], public exposure/CY per mile transported [highway accident], release to environment/gallons treated [treatment system upset]).

There are limited short-term risks associated with Alternative 1 (MNR). Limited construction for bank stabilization, along with monitoring, would be conducted under this alternative. Alternative 1 scores the highest under this criterion.

Alternative 2 (EMNR) has slightly greater short-term risk as a result of the additional construction required to place sand for ENR; however, the complexity and magnitude of construction to implement the remedy are low compared to other alternatives, resulting in a high rating for the management of short-term risks.

Alternative 3 (Engineered Cap) requires removal of sediment to maintain the navigation depth, in addition to placing significantly more material than in Alternative 2. This alternative has a higher potential than Alternatives 1 and 2 for resuspending contamination and stimulating transport of contaminated sediments off site during dredging; however, proper controls during construction can greatly reduce that potential. Further, constructing the cap is more complex than the ENR placement applied in Alternative 2 because an additional armored layer is required. Alternative 3 scored in the middle with these considerations.

Alternative 4 (Dredge and ENR) scores in the middle for short-term risk, as the amount of sediment to be transported off site for disposal is significant and has the potential to detrimentally affect human health or the environment if handled improperly. Alternative 4 also has the highest potential for resuspension and off-site transport of contaminated sediments; however, construction controls known to be effective in managing this risk would be employed, mitigating the overall risk.

Technical and Administrative Implementability

This factor addresses whether the alternative can be implemented and is technically possible. The availability of necessary materials; regulatory requirements; scheduling; access for construction operations and monitoring; and integration with existing facility operations must be considered.

All the alternatives use proven sediment-remediation technologies that have been employed at many sites. All four are implementable from a technical and administrative perspective.

Alternative 1 (MNR) entails significant administrative requirements, such as placing and maintaining institutional controls at Lake River, that restrict current uses, shore access, and navigation, among others. Additionally, the ongoing monitoring plan and sampling events would add to the administrative components. Restrictions on future use would also be required and would rely on the long-term effectiveness of communication of the hazards associated with the river sediments. A lower score is the result.

Alternative 2 (EMNR) has the same administrative requirements as Alternative 1, with the addition of the permitting and approvals required for project construction. The ENR layer does not impose any technical difficulties, nor does it increase the administrative requirements; it is therefore scored the same as Alternative 1.

Alternative 3 (Engineered Cap) is more easily implemented, as engineered sediment caps have been successfully constructed in many locations around the country. The alternative requires the mobilization of marine equipment past the confluence of Lake River and the Columbia River, introducing some technical logistics issues. Added complexity would also be manifested in the permitting process. Alternative 3 requires institutional controls and ongoing monitoring and maintenance of the cap. Alternative 3 is ranked in the middle for this criterion.

Alternative 4 (Dredge and ENR) is implementable, although the project will require multiple permits and approvals to complete. Because Alternative 4 does not require institutional controls, it is ranked higher under this criterion.

Consideration of Public Concerns

This factor includes considering concerns from individuals, community groups, local governments, tribes, federal and state agencies, including DNR (i.e., the landowner, and therefore the owner, of the sediments), and any other organization that may have an interest in or knowledge of Lake River and that may have a preferred alternative. Specifically, the following agencies will have input in the process through permitting:

- The COE will review the design of the selected alternative and permit the project upon input from natural resource trustees and tribes.
- DNR will have input in the remedy selection process through permitting of the preferred alternative and/or implementation of institutional controls.

Ecology has addressed community concerns throughout the history of the associated project sites. Additional issues or concerns of DNR, other agencies, and the public will be considered by Ecology as part of the cleanup action selection process. Public comments on the project and this document will be solicited from the community during the formal comment period, following Ecology input. Common community concerns include noise and traffic, short- and long-term risks, and the time frame for any proposed cleanup actions. Community concerns will also be factored into local permit processes, including responding to the City's shoreline ordinance and development permitting. All alternatives are scored high for this criterion because they have the same permitting and public comment processes.

Cost

The detailed cost estimates for Alternatives 1, 2, 3, and 4 are provided in Tables R-3, R-4, R-5, and R-6, respectively, and can be found in Appendix R. Primary assumptions, unit costs, and number of units for all significant project elements are included. Net present value calculations are also included for operation, maintenance, and monitoring costs, if applicable. The estimated net present value costs for implementation, operation and maintenance, and monitoring are as follows:

• Alternative 1 (MNR):	$679,000
• Alternative 2 (EMNR):	$2.8 million
• Alternative 3 (Engineered Cap):	$7.7 million
• Alternative 4 (Dredge and ENR):	$9.5 million

As shown in Table 9-1, Alternative 4 is the most permanent of the alternatives. The associated costs are considered proportionate to the level of risk reduction achieved in comparison to other, lower-cost, alternatives. Alternative 1 has the lowest cumulative score and has a significant amount of uncertainty in achieving protectiveness within a reasonable restoration time frame. Alternative 3 scores lower than Alternative 4 and retains a similar remedy cost (depending on the amount of dredging that is incorporated into the alternative to accommodate navigation considerations). Alternative 2 has a relatively low cost compared to Alternative 4; however, Alternative 4 achieves a significant increase in protectiveness as well as a higher cumulative score compared to Alternative 2. Based on the DCA findings, Alternative 4 is considered permanent to the maximum extent practicable.

10 FEASIBILITY ANALYSIS: CARTY LAKE

Carty Lake is a 52-acre ponded wetland located in the RNWR Carty Unit immediately north of Cell 2 and west of LRIS Cell 4, formerly used by PWT for untreated wood storage. See Section 2.2.4 of this report for further background information on this area.

10.1 Technology Screen

Consistent with the SMS requirements found in WAC 173-204-560(4)(f)(iii) and using MTCA procedures as a guideline (WAC 173-340-350(8)(b)—Screening of Alternatives), individual cleanup action components (technologies) were reviewed and screened to identify applicable methods for remediating the sediment in Carty Lake. The preliminary screening of applicable technologies reviewed technologies that are identified in the FRTR (2008), as well as other commonly used remediation methods. Effectiveness and implementability of the technologies were assessed for the contaminants in the sediment, resulting in a list of technologies that were retained for further consideration (see Table O-2, Appendix O).

10.2 Development of Remediation Levels

Human health and ecological CULs were developed for dioxins in Section 6 and are presented in Table 6-5. Elevated dioxins (i.e., above CULs) are colocated with contaminants that exceed screening criteria identified in Section 3. Therefore, any remedy directed at dioxins is expected to remedy other contaminants. Because Carty Lake is part of the RNWR, it is an important resource for ecological receptors. The REL is set at a level protective of ecological receptors, i.e., at the ecological CULs for dioxin congeners described in Section 6.

10.3 Alternatives

Remedial alternatives for Carty Lake were developed based on the cleanup technologies identified in the technology screening (Table O-2, Appendix O) and the CULs presented in Section 6. Individual remedial technologies have been assembled into comprehensive alternatives that accomplish the remedial action goals for impacted sediment. Three remedial alternatives were developed for Carty Lake that meet ecological CULs with institutional controls that protect human health. RELs for the Carty Lake alternatives have been set equivalent to ecological CULs. Because Carty Lake is part of the RNWR, it will be necessary to coordinate alternatives with USFWS and ensure that they are consistent with USFWS plans for Carty Lake. It is understood that at this time USFWS is considering reconnecting Carty Lake with the Columbia River. A no action alternative was considered, but it was dismissed from further evaluation, as it does not address cleanup standards. The remedial alternatives are described below (see Appendix T for detailed analysis) and are evaluated in Section 10.4.

10.3.1 Alternative 1: Monitored Natural Recovery

Primary components of Alternative 1 are:

- Natural attenuation
- Long-term monitoring program
- Institutional controls to protect human health

Alternative 1 relies on MNR and institutional controls to achieve cleanup standards. Natural recovery occurs under favorable conditions over an indeterminate period of time and acts without human intervention. The deposition rate for sediment in Carty Lake depends on many variables, including lake morphology, water circulation, climate conditions, and catchment area. At Carty Lake, many of these conditions are known; however, further analysis of the hydrodynamic processes occurring in Carty Lake would be required to quantify the expected time frame for sufficient sedimentation to occur.

A comprehensive work plan would be prepared outlining methods for monitoring techniques and sampling events. The plan would define sampling locations and methods within the study area perimeter. The monitoring program would be developed with the objective of verifying the ongoing effectiveness of recovery of contaminated sediment by natural processes. The monitoring would quantify the reduction in concentrations relative to RELs.

Restrictions on access and future land use (short-term) and advisories on fish consumption would all be included as institutional controls. Additional evaluations may be necessary before Carty Lake is reconnected with the Columbia River.

10.3.2 Alternative 2: Focused Dredge and Limited Residuals Cap

Primary components of Alternative 2 are:

- Dredging sediment above RELs
- Placement of a residuals cap layer over the dredged area
- Natural attenuation
- Long-term monitoring
- Institutional controls to protect human receptors

Alternative 2 consists of removing approximately 5,650 CY of sediment above RELs in the southeast corner of Carty Lake by means of dredging and disposal. The areal extent of the dredge area is estimated in this FS using Thiessen polygons but would be refined during design. Figure 10-1 shows the estimated lateral and vertical extent of the dredge prism and the anticipated resulting postremedial conditions. The USFWS will be consulted regarding the development of the specific design for the dredge area.

The location of the impacted sediments would allow dredging from an upland position, with tracked equipment. Dewatering and solidification of the dredged material in the upland area would be required before landfilling.

Dredged material would be disposed of as nonhazardous material at a local Subtitle D landfill. Data results have been reviewed for waste designation purposes, and the dredged material would not be designated as either a RCRA-listed hazardous waste or a RCRA characteristic waste.

A silt curtain would provide adequate containment of sediment entrained during dredging, and water quality would be monitored outside the dredge area before, during, and after construction.

Approximately 2,700 CY of sand would be placed in a 6- to 12-inch-thick layer over dredged areas and the resulting residuals that are assumed to be contained within the dredge footprint (see Appendix T). The thin layer sand cap is comparable to the ENR layer considered in Alternatives 2 and 4 for Lake River (see Section 9), but is less likely to be disturbed because Carty Lake is a quiescent environment. In addition, motorboats are not allowed on the lake, so propeller-induced mixing of the sand cap layer will not occur. Sand placement for the residuals cap would be conducted from shore, using tracked equipment. Access improvements may be required and likely would include clearing and grubbing and construction of a staging area.

The monitoring program would be developed with the objective of verifying the ongoing effectiveness of recovery of contaminated sediment by natural attenuation. The monitoring would quantify the reduction in concentrations relative to the CUL (5 ng/kg dioxin TEQ) and would evaluate whether institutional controls associated with fish consumption would be appropriate.

Advisories on fish consumption would be included as institutional controls, and additional evaluations may be necessary before Carty Lake is reconnected with the Columbia River.

10.3.3 Alternative 3: Focused Dredge and Expanded Residuals Cap

Alternative 3 consists of the same elements found in Alternative 2, but with additional ENR placement in areas of somewhat elevated dioxin concentrations (i.e., sample locations LRIS-CL-07 and LRIS-CL-09). See Figure 10-1 for the estimated lateral and vertical extent of dredging and the areal extent of residuals cap placement. Note that extents are estimated using Thiessen polygons. Actual extents will be refined during design, in consultation with the USFWS. For purposes of this FS, the polygons surrounding sediment samples LRIS-CL-07 and LRIS-CL-09 are used to estimate the area of ENR placement beyond the dredged area.

Following the removal of 5,650 CY of contaminated sediment in the southeast corner of the lake (using the same RELs as for Alternative 2), approximately 12,800 CY of sand for a residual cap layer would be placed in a 6- to 12-inch-thick layer over a selected portion of Carty Lake. Because the lake is a quiescent environment, the residuals layer would also act to provide an isolation layer over impacted bottom sediments. Carty Lake is a low-energy, low-traffic (e.g., no boats allowed), quiescent environment, and consequently the likelihood that the residuals cap would be disturbed is low. Should Gee Creek be hydraulically connected to Carty Lake in the future, the design of the connection should take into account the possibility that any high-velocity connection will result in changed fluvial conditions that could encourage sediment transport.

Sand placement for the residuals cap likely would be conducted using a combination of shore-based equipment and floating equipment. The material would be placed either from shore, using a conveyed aggregate system or similar, or from segmented floating barges.

10.3.4 Alternative 4: Focused Dredge and Full Residuals Cap

Alternative 4 consists of the same elements found in Alternatives 2 and 3, with the addition of residuals cap placement over all areas of the Carty Lake bottom sediments that have concentrations above the CUL of 5 ng/kg dioxin TEQ. See Figure 10-1 for the estimated lateral and vertical extent of dredging and the areal extent of residuals cap placement. Note that extents are estimated using Thiessen polygons. Actual extents will be refined during design, in consultation with the USFWS.

Following the removal of 5,650 CY of contaminated sediment in the southeast corner of the lake (using the same RELs as Alternative 2), approximately 82,000 CY of sand for a residuals cap layer would be placed in a 6- to 12-inch-thick layer over most of Carty Lake. Because the lake is a quiescent environment, the residuals layer would provide the additional benefit of an isolation layer over impacted bottom sediments.

Sand placement for the residuals cap would require floating equipment for spreading sand hydraulically. Access improvements most likely would include clearing and grubbing and construction of a staging area to provide ingress to the entire lake for sand cap placement.

10.4 Detailed Alternative Analysis

The cleanup action alternatives related to Carty Lake sediments were evaluated using the SMS guidelines listed in WAC 173-204-560(4)(f)(iii) A through D, as described below. The SMS require that each cleanup study plan include an evaluation of alternative cleanup actions that protect human health and the environment by eliminating, reducing, or otherwise controlling risks posed by each exposure pathway and migration route.

10.4.1 SMS Evaluation Requirements

The proposed cleanup action alternatives must be evaluated consistent with the requirements of the SMS. The SMS requirements in WAC 173-204-560(4) are worded similar to MTCA evaluation requirements, although they are structured slightly differently. The SMS list the following evaluation criteria to assess the cleanup action alternatives that pass the initial screening (technology screen):

- Overall protection of human health and the environment
- Attainment of the cleanup standard(s) and compliance with applicable federal, state, and local laws
- Short-term effectiveness
- Long-term effectiveness

10.4.1.1 Protection of Human Health and the Environment

According to the SMS, considerations for the protection of human health and the environment include overall protectiveness of the alternative, time required to attain the cleanup standard(s), and on-site and off-site environmental impacts and risks to human health resulting from implementing the cleanup alternative.

Each of the four alternatives protects human health and the environment through compliance with cleanup standards, removal and capping of impacted sediment, and/or institutional controls to manage the potential for exposure to impacted sediment.

Alternative 1 (MNR) is somewhat protective of human health and the environment. This alternative consists of monitoring the natural recovery of sediment within the cleanup boundary and implementing institutional controls, including restrictions on current and future uses and on site access. Natural recovery of Carty Lake sediments would involve the slow deposition of clean sediment on top of existing impacted sediment, natural degradation of contaminants, and/or the natural dispersion of contaminated materials. Implementing the components associated with Alternative 1 would eventually prevent unacceptable exposure to the impacted sediment, relying in the short term on institutional controls. Alternative 1 has few to no on-site or off-site impacts resulting from implementation, as there is no handling of material, and exposure during implementation is limited to sampling events. Alternative 1 relies on natural processes to attenuate contamination in the sediment. This requires an extended time frame. Because there are few sediment inputs to Carty Lake, the time frame for attenuation could be extensive, increasing the possibility of exposure to contaminants and the likelihood that institutional controls will be ignored.

Alternative 2 (Focused Dredge and Limited Residuals Cap) is protective of human health and the environment. This alternative includes removal of sediments exceeding RELs, placement of a residuals cap layer of clean sand, and institutional controls to prevent human consumption of fish. Alternative 2 results in a SWAC of 24 ng/kg dioxin TEQ (see Appendix T). Implementation of Alternative 2 would have some on-site and off-site impacts, as the alternative includes handling, transportation, and off-site disposal of the sediment; however, proper controls during implementation can limit these exposure potentials. Implementing the alternative would, over the short and long terms, prevent exposure to contaminants in sediment exhibiting the highest concentrations. The residuals cap layer of clean sand placed directly over the dredged area would prevent contact with generated residuals.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) is protective, incorporating the same processes and technologies as Alternative 2, but with additional ENR placement in areas of somewhat elevated dioxin concentrations (i.e., sample locations LRIS-CL-07 and LRIS-CL-09), and the SWAC of Carty Lake would be marginally less at 22 ng/kg dioxin TEQ.

Alternative 4 (Focused Dredge and Full Residuals Cap) is protective, as it removes impacted sediment and places a residuals cap layer over the entire Carty Lake footprint. All of the low-level impacts would be covered by the cap layer. The amount of highly impacted sediment removed from the lake would be the same as in Alternative 2; however, with the expanded placement of the sand cap, the SWAC is estimated to be significantly less at 12 ng/kg dioxin TEQ.

10.4.1.2 Compliance with Cleanup Standards and Applicable Federal, State, and Local Laws

This cleanup action is being conducted under the SMS (WAC 173-204). All cleanup alternatives will be conducted consistent with applicable state and federal laws.

The alternatives are anticipated to meet the CUL only after extended time frames. Alternatives 2, 3, and 4 are all anticipated to achieve RELs immediately upon completion of the active remedy. Alternative 1 (MNR) would require the longest time frame to meet the CUL and RELs; it is likely to require more than ten years to meet these levels, given the low level of sediment input to the lake. Alternative 4 (Focused Dredge and Full Residuals Cap) would require the shortest amount of time to reach the CUL because the initial placement of a clean layer of sand would cover all concentrations above the CUL. Alternatives 2 (Focused Dredge and Limited Residuals Cap) and 3 (Focused Dredge and Expanded Residuals Cap) are likely to result in similar time frames to achieve the CUL and would likely require less time than Alternative 1 and more time than Alternative 4.

10.4.1.3 Short-Term Effectiveness

According to the SMS, analysis of the short-term effectiveness includes consideration of the protection of human health and the environment during construction and implementation of the alternative.

Alternative 1 (MNR) provides little effective protection in the short term; however, exposure potentials are also lowest, as no construction activities would take place. Alternative 1 would take the longest to achieve overall protectiveness, as it relies on natural processes.

Alternative 2 (Focused Dredge and Limited Residuals Cap) provides short-term effectiveness because a residuals cap layer would be placed over dredged locations where elevated concentrations of contaminants had been removed and where residuals may occur. The residuals cap would act as a physical barrier between the environment and any remaining contamination. However, Alternative 2 leads to more short-term exposure to contaminants during construction and implementation because of dredging of the sediments and subsequent handling of the dredged material.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) provides short-term effectiveness, incorporating the same processes and technologies as Alternative 2, but with placement of an additional ENR layer in areas of somewhat elevated dioxin concentrations. Alternative 3 leads to approximately the same amount of short-term exposure during implementation as Alternative 2.

Alternative 4 (Focused Dredge and Full Residuals Cap) allows for the same amount of short-term exposure during dredging as in Alternatives 2 and 3, with very slightly increased overall exposure potential during implementation due to more extensive cap placement. As in Alternative 2, the sand layer would act as a physical barrier between the environment and the contamination, but would be extended to all of Carty Lake and would function as a cap covering all sediment above the CUL, isolating surface contamination on a larger, more permanent scale. However, this extensive sand placement may significantly disturb benthic biota throughout the lake (and associated biota that rely on benthics).

10.4.1.4 Long-Term Effectiveness

Pursuant to the SMS, the following were considered in analyzing the alternatives for the threshold requirements pertaining to long-term effectiveness: degree of certainty that the alternative will be successful; long-term reliability; magnitude of residual, biological, and human health risk; and effectiveness of controls for ongoing discharges and/or controls required to manage treatment residues, remaining wastes cleanup, and/or disposal site risks.

Alternative 1 (MNR) can be effective in the long term, provided that the natural attenuation mechanisms are operating and are understood to the extent that a completion time frame can be predicted. The attenuation would be closely monitored to prove that recovery is occurring and that residual, biological, and human health risk is being mitigated. No disposal site risks are associated with this alternative. Restrictions would be placed on future uses in order to protect human receptors, increasing long-term effectiveness if the restrictions are followed.

Alternative 2 (Focused Dredge and Limited Residuals Cap) provides a higher degree of long-term effectiveness due to removal of highly impacted sediment and placement of a physical barrier over a selected area of residual impacted sediment. Removing the higher concentrations of dioxins and other contaminants in the southern portion of Carty Lake eliminates unacceptable risk to ecological receptors and reduces the long-term risk to human health. Protection of human health depends on effectiveness of institutional controls. The implementation of a residuals cap layer will mitigate the effect of post-dredging surface residuals. Additionally, the removal of the most impacted sediments eliminates the potential for future transport of these chemicals as a result of uncommon events, such as floods or seismic events. Dredging is common and has a relatively high degree of certainty for success, and the long-term reliability is high. The disposal site would be an operating landfill with established controls in place to adequately contain impacts associated with these sediments.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) provides a slightly higher degree of long-term effectiveness due to removal of highly impacted sediment and placement of an additional ENR cap (compared to Alternative 2); the cap acts as a physical barrier over the selected area of residual impacted sediment. Alternative 3 incorporates the same processes and technologies as Alternative 2.

Alternative 4 (Focused Dredge and Full Residuals Cap) provides effectiveness comparable to that of Alternative 2, attributable to the removal of the most contaminated sediment. However, Alternative 4 improves on the long-term effectiveness of Alternatives 2 and 3 through the addition of a more extensive sediment cap layer, which would isolate surface concentrations on a wider, more permanent scale than with Alternative 2.

10.4.2 Cleanup Time Frame

WAC 173-204-580(3) contains guidance for determining reasonable time frames for completing cleanup actions. The cleanup action selected will provide for a reasonable time frame for completion of the cleanup action, based on the many factors addressed throughout this report as well as on the following: practicability of achieving the site cleanup standards in less than a ten-year period; current use of the Site and surrounding areas; and potential future use of the Site and surrounding areas.

Current sediment concentrations exceed CULs for protection of human health and the environment, requiring the shortest cleanup time frame practicable. Alternatives 2, 3, and 4 provide a relatively quick cleanup time frame, achieving the RELs (ecological cleanup standards) well within the ten-year time frame, while institutional controls would immediately take effect to protect human health.

Alternative 1 (MNR) relies on natural deposition to achieve site cleanup standards and likely would have a significantly longer cleanup time frame than Alternatives 2, 3, and 4 because the contaminated sediment would not be removed or capped. Natural attenuation through sedimentation may not occur in Carty Lake within the ten-year time frame because sediment inputs to the lake are limited. Extensive limitations on current and future site uses would be required.

Alternative 2 (Focused Dredge and Limited Residuals Cap) and Alternative 3 (Focused Dredge and Expanded Residuals Cap) would require relatively short and comparable cleanup time frames because of the removal of material and placement of clean sediment over any residual impacts in the dredge area (and additional areas, in the case of Alternative 3). Alternatives 2 and 3 would both achieve CULs protective of ecological receptors in well under ten years, accounting for pre-implementation sampling and planning, in addition to remedy implementation. Achieving the human health CUL (based on the PQL) in all lake sediments would rely on natural recovery and may exceed the ten-year time frame; however, institutional controls would take effect immediately to protect human health.

Alternative 4 (Focused Dredge and Full Residuals Cap) would achieve the shortest cleanup time frame because of the placement of the more extensive sediment cap, immediately isolating surface contaminant concentrations across the entire lake. However, while the SWAC would be lower upon remedy implementation than for Alternatives 2 and 3, it may still take a considerable amount of time for natural recovery to achieve the human health CUL (based on the PQL).

The current use of Carty Lake and surrounding areas allows for implementation of all of the action alternatives; however, the institutional controls implemented at Carty Lake are varied in their likely effectiveness and reliability.

10.4.3 Evaluation of Alternatives

In WAC 173-204-580(4), the SMS specifies that, in evaluating the alternatives, the net environmental effects, relative cost effectiveness, and relative technical effectiveness should be considered for the cleanup action alternatives. For the purposes of performing a comprehensive assessment, cost and technical effectiveness were evaluated together, using the MTCA DCA framework because it addresses the above SMS requirements as well as additional requirements found in WAC 173-204-560(4)(g-k).

10.4.3.1 Net Environmental Effects

This requirement includes consideration of the net environmental effects of the alternatives, including residual effects, recovery rates, and any adverse effects of cleanup construction or disposal activities.

The implementation of Alternative 1 (MNR) results in no net change to the existing environmental system, on site or off. The alternative relies purely on current natural processes and the monitoring of those processes to ensure that the RELs and the CUL are eventually achieved.

Alternatives 2 through 4 all pose a short-term risk associated with generated residuals; however, engineering controls and dredging best management practices would be part of the design. Specified dredging methods such as bucket types, precision targeted removal, number of passes, and the implementation of a residuals layer (to name a few) would all be employed to reduce and control the generation of residuals.

Alternative 2 (Focused Dredge and Limited Residuals Cap) has the potential for much greater environmental impacts than Alternative 1; however, it also achieves a greater level of long-term protectiveness. If properly managed, dredging and disposal of impacted sediment would not affect water quality and aquatic or terrestrial organisms. Comprehensive planning, design, and management of the project would allow disposal of dredged material in an efficient and environmentally appropriate manner. Alternative 2 would result in a greater benefit than Alternative 1 through the removal of a significant mass of contaminants and the immediate reduction of potential exposure to the highest levels of contamination.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) has the same potential for environmental impacts as Alternative 2, as the same processes and technologies are involved.

Alternative 4 (Focused Dredge and Full Residuals Cap) would result in a marginal net environmental benefit over Alternatives 2 and 3, as it poses the same amount of risk associated with the removal of impacted sediments. More clean sand would be placed over the impacted sediments, resulting in a greater, areawide isolation of surface concentrations over the short and long terms; however, significantly greater disturbance of lake biota would occur than in Alternatives 1 and 2, given the large area that would be covered with an ENR layer. The clean sediment for the residuals cap likely would be a waste material from maintenance activities in the Columbia River channel, so an additional negative impact on the system would result from the additional transportation to Carty Lake.

10.4.3.2 Relative Cost and Technical Effectiveness

The MTCA DCA was implemented to evaluate the relative costs and benefits of the sediment remediation alternatives. The criteria for performing the DCA can be found below. All alternatives meet the threshold criteria and were included in the DCA.

Costs are determined to be disproportionate to benefits if the incremental cost of a more expensive alternative over that of a lower-cost alternative exceeds the incremental degree of benefits achieved by the more expensive alternative. The DCA includes evaluation criteria that are a mix of qualitative and quantitative factors, including protectiveness, permanence, long-term effectiveness, management of short-term risks, technical and administrative implementability, consideration of public concerns, and cost. A summary of the analysis is provided in Table 10-1. Detailed cost estimates are provided as Appendix R.

Protectiveness

Protectiveness of human health and the environment includes the degree to which existing risks are reduced; time required to reduce risk at the facility and attain cleanup standards; on-site and off-site risks resulting from implementing the cleanup action alternative; and improvement of the overall environmental quality.

As discussed in the evaluation requirements (Section 10.4.1), Alternatives 1, 2, 3, and 4 are protective of human health and the environment. The degree of protectiveness varies and the alternatives are scored in the following order:

Alternative 1 (MNR) is rated lower for protectiveness, as this alternative relies on natural processes to create a physical barrier, as well as on institutional controls to protect receptors.

Alternative 2 (Focused Dredge and Limited Residuals Cap) is rated in the middle for protectiveness, as contaminants would be removed to RELs and a residuals cap layer would limit exposure of residual impacts in the dredge area. Impacted sediments above the CUL would remain and institutional controls would be required to protect human health.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) is rated in the middle for protectiveness because the only difference between Alternatives 2 and 3 is an increase in the amount of residuals cap coverage. The additional sand placement will result in a minimally reduced SWAC (see Table T-1, Appendix T).

Alternative 4 (Focused Dredge and Full Residuals Cap) is above the middle for protectiveness. The action consists of the same removal scenario as in Alternatives 2 and 3, with the addition of a sediment cap layer placed over most of the lake bottom, covering most impacted sediments.

Permanence

Permanence is a factor by which the cleanup action alternative permanently reduces the toxicity, mobility, or volume of hazardous substances. The adequacy of the alternative in destroying the hazardous substances, the reduction or elimination of hazardous substance releases and sources of releases, the degree of irreversibility of the waste-treatment process, and the characteristics and quantity of treatment residuals generated are all considered under this criterion.

Under the MTCA DCA process, preference is given to permanent solutions to the maximum extent practicable. A “permanent solution” is defined as a cleanup action in which the cleanup standards are met without further action being required at the site being cleaned up or at any other site involved with the cleanup action, other than the approved disposal of any residue from the treatment of hazardous substances.

Alternative 1 (MNR) has the lowest level of permanence and is rated as such. Sediment exceeding CULs would remain in place and would be accessible to biological and human receptors in the short and long terms. The alternative also must include continued monitoring of the deposited sediment, and must also rely on institutional controls to protect the sediment layer from damage.

Alternative 2 (Focused Dredge and Limited Residuals Cap) is rated in the middle under this criterion, as contaminated sediment is removed and (assumed) residuals are covered by a residuals cap layer. The relative longevity and effectiveness of the residuals cap layer will be less quantifiable, as it is not an engineered cap and cannot be relied upon as such; however, the fluvial environment in Carty Lake is not highly dynamic, and impairment to the residuals cap surface would not occur as a result of human activity (e.g., propeller wash).

Alternative 3 (Focused Dredge and Expanded Residuals Cap) is rated the same as Alternative 2 under this criterion. The two alternatives incorporate the same processes and technologies, with Alternative 3 increasing the amount of residuals cap placement. The alternative is still a partial capping alternative, however, and is not fundamentally different enough from Alternative 2 to be considered more permanent.

Alternative 4 (Focused Dredge and Full Residuals Cap) rates higher for permanence. The removal of sediment makes both Alternatives 2 and 3 highly permanent; however, the addition of a sediment cap over most of the Carty Lake bottom sediments results in Alternative 4 scoring the highest of the four alternatives under this criterion.

Effectiveness over the Long Term

In addition to the threshold requirements discussed in Section 10.4.1.4, long-term effectiveness in the DCA includes the degree of certainty that the alternative will be successful; the reliability of the alternative for the period of time during which hazardous substances are expected to remain on site at concentrations that exceed CULs; the magnitude of residual risk with the alternative in place; and the effectiveness of controls required to manage treatment residues or remaining wastes.

With proper implementation, all four alternatives can be effective over the long term under this criterion; therefore, they were rated based on the degree of certainty of effectiveness.

Alternative 1 (MNR) may be effective in the extreme long term, provided that the natural processes occur without incident and that the institutional controls are effective. These variables produce a great deal of uncertainty, resulting in the lowest rating of the four alternatives.

Alternative 2 (Focused Dredge and Limited Residuals Cap) is rated in the middle under this criterion, as the alternative removes contaminated sediment and adds a residuals cap layer for the purposes of managing residuals only in the dredged area, with the rest of the footprint of the lake relying on natural recovery over time and on institutional controls to protect human receptors. The degree of certainty in long-term effectiveness is somewhat lower because of the potentially slow process of sedimentation at the Site.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) is rated the same as Alternative 2 for this criterion because the two alternatives are essentially the same. Because the dioxin TEQ SWAC is not meaningfully reduced by the additional cover of contaminated sediments, Alternative 3 does not result in a significant increase in long-term effectiveness.

Alternative 4 (Focused Dredge and Full Residuals Cap) is most effective over the long term, as contaminated sediment is removed and a cap is placed over the entire lake. This effectively isolates more impacted sediments relative to the other alternatives, and therefore scores higher.

Management of Short-Term Risks

As discussed in the evaluation requirements (Section 10.4.1.3), this factor addresses the risk to human health and the environment associated with the alternative during construction and implementation, and the effectiveness of measures that will be taken to manage such risks. Short-term risks to remediation workers, the general public, and the environment are assessed under this criterion. Generally, short-term risks are expected to be linearly related to the amount of material handled, treated, and/or transported/disposed of (e.g., worker injury/CY dredged [equipment failure], public exposure/CY per mile transported [highway accident], release to environment/gallons treated [treatment system upset]).

There are no construction-related short-term risks associated with Alternative 1 (MNR), and therefore Alternative 1 is rated the highest under this criterion.

Alternative 2 (Focused Dredge and Limited Residuals Cap) removes sediment, increasing the potential to detrimentally affect human health or the environment if the sediment is handled improperly, but is overall a much less intensive implementation process than Alternative 4, decreasing short-term risks associated with construction and resulting in a middle rating.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) removes the same amount of sediment as in Alternative 2, but rates in the middle because of the increase in sand placement, which extends the construction time. The extended work period slightly increases the short-term risks associated with construction.

Alternative 4 (Dredge and Full Residuals Cap) is rated lowest, as a significantly larger amount of sand would be placed on site than in Alternative 2 or 3, greatly increasing the amount of construction activity associated with the alternative. The greater construction effort would result in an increased potential for risk exposure during implementation because of the longer construction period.

Technical and Administrative Implementability

This factor addresses whether the alternative can be implemented and is technically possible. Regulatory requirements, scheduling, access for construction operations and monitoring, integration with existing facility operations, and the availability of necessary materials must be considered.

All the alternatives use proven technologies for remediating sediment and have been employed at many sites. All three are implementable from a technical and administrative perspective.

Alternative 1 (MNR) entails significant administrative requirements such as placing and maintaining institutional controls at Carty Lake that restrict current uses and lake access and that place limits on biological intake, among other measures. Additionally, the ongoing monitoring plan and sampling events will add to the administrative components. Restrictions on future use will also be required and will rely on the long-term effectiveness of communicating the hazards associated with the lake sediments, resulting in a lower ranking for this alternative.

Alternative 2 (Focused Dredge and Limited Residuals Cap) is implementable, as mechanical dredging is straightforward. The alternative presents some difficulty in managing sediment for off-site disposal and in gaining access to Carty Lake, with limited impacts to the surrounding wetland area introducing some technical and logistical issues. In addition, Alternative 2 demands a significant number of administrative requirements, such as institutional controls and ongoing monitoring and maintenance of the residuals cap, in addition to monitoring the natural recovery of the remaining sediments. Alternative 2 is scored highest for this criterion.

Alternative 3 (Focused Dredge and Expanded Residuals Cap) is slightly less implementable than Alternative 2 because of the amount and location of sand placement. The enlarged placement area would require more access improvements as well as possible floating equipment for sand placement, increasing the technical demand.

Alternative 4 (Focused Dredge and Full Residuals Cap), like Alternatives 2 and 3, is implementable and poses the same type of complexities and site access limitations; however, Alternative 4 requires a great deal more access to the entirety of Carty Lake, causing increased logistical and site constraints over Alternative 2. Alternatives 2, 3, and 4 require ongoing administrative action in a shorter time frame than for Alternative 1, resulting in a higher ranking for these alternatives, with Alternative 2 ranking highest because of fewer site constraints during implementation.

Consideration of Public Concerns

This factor includes considering concerns from individuals, community groups, local governments, tribes, federal and state agencies, and any other organization that may have an interest in or knowledge of Carty Lake and that may have a preferred alternative.

Ecology has addressed community concerns throughout the history of this project. Additional issues or concerns will be evaluated by Ecology as part of the cleanup action selection process. This includes consideration of public use of Carty Lake. Remedy selection and potential institutional controls will be coordinated with the USFWS, particularly because remedy selection has the potential to impact RNWR plans for restoring the Carty Lake-Gee Creek connection. Public comments on the project and on this document will be solicited from the community during the formal comment period, following Ecology input. Common community concerns include noise and traffic, short- and long-term risks, and the time frame of any proposed cleanup actions. Community concerns will also be factored into local permit processes, including responding to the City's shoreline ordinance and development permitting. Alternative 1 has the potential to be less open to the public because it is unlikely that there will be permitting requirements that provide opportunities for public comment.

Cost

The detailed cost estimates for the alternatives are provided in Appendix R, Tables R-9 through R-12, respectively. Primary assumptions, unit costs, and number of units for all significant project elements are included. Net present value calculations are also included for operation, maintenance, and monitoring costs, if applicable. The estimated net present value costs for implementation, operation and maintenance, and monitoring are as follows:

• Alternative 1 (MNR):	$280,500
• Alternative 2 (Focused Dredge and Limited Residuals Cap):	$1.6 million
• Alternative 3 (Focused Dredge and Expanded Residuals Cap):	$2.3 million
• Alternative 4 (Focused Dredge and Full Residuals Cap):	$7.3 million

Alternative 2 provides a much greater degree of protectiveness and long-term effectiveness for an incremental cost of approximately $1.6 million when compared to Alternative 1. Alternative 3 costs nearly half again as much as Alternative 2 and results in nearly the same postremedial dioxin TEQ SWAC; therefore, Alternative 2, with less ENR placement, is more cost effective, and Alternative 3 is rejected as disproportionately costly. When considering Alternative 4's large cost discrepancy and its limited incremental benefit over the other alternatives, Alternative 4 is disproportionately costly and is rejected as an alternative.

11 DESCRIPTION OF PREFERRED ALTERNATIVE

The preferred remedial alternatives for the upland and in-water components of the LRIS and associated sites are described in this section. Remedy selection is based on the alternatives analysis and the associated criteria described in MTCA and SMS guidance documents. The upland on-property emergency and interim actions have already been implemented and/or approved and are identified below.

11.1 Soil

The FS was conducted to establish the optimum approach for cleanup activities on the LRIS and the upland off-property area in order to protect human health and the environment. The analyses for on-property soil are summarized in Section 7, and off-property soil analysis is presented in Section 8. As part of the FS, several remedial technologies were evaluated, and detailed remedial alternatives were investigated for each location at the Site: Cells 1 and 2, Cell 3, Cell 4, and the upland off-property area. The recommended alternatives of the on-property analyses and the off-property analysis are described below and are based on the results of the DCA and the comparative evaluation of the alternatives.

11.1.1 LRIS

The selected remedial actions for Cells 1, 2, 3, and 4 for soil included: removal of soil in the concrete pond source area, removal of soil outside the SER area that exceed preliminary RELs, and sitewide capping (Alternative 2B in the Cells 1 and 2 FS, Alternative 2 in the Cell 3 FS, and Alternative 2 in the Cell 4 FS). These actions were determined to be both cost effective and protective of human health and the environment. As indicated in the cell-specific FSs, the interim actions for the LRIS were anticipated to be the final actions for the LRIS.

The relative toxicity of the IHSs at the LRIS site is moderate to high. The interim cleanup actions in Cells 1 through 4 resulted in elimination of the potential risk posed by the IHSs to human health and the environment. Cell-specific interim actions are described in the subsections below. Overall LRIS interim actions will eliminate exposure to receptors by:

- Removal of all historical structures (e.g., buildings, railroad tracks, surface completions) except the Port office building
- Removal and off-site disposal of highly contaminated soils in the concrete pond source area
- Removal and off-site disposal of highly contaminated soils outside the SER area that exceed the preliminary RELs
- Capping contaminated soil within the LRIS property boundary

- Separation of the consolidated contaminated soil from sensitive receptors such as surface water bodies, terrestrial ecologic receptors, and drinking water sources
- Removal of the existing stormwater system and installation of a new stormwater system
- Implementing institutional controls to ensure containment of contaminated soil

The following summarizes the selected remedial alternative components.

11.1.1.1 Cells 1 and 2

Implementation of the selected interim action components is completed or is currently under way and scheduled for completion in 2013. Remedial action elements are as follows:

- Soil in the concrete pond area with observed NAPL impacts was excavated, transported, and disposed of at a Subtitle C landfill.
- Soil outside the SER area with IHSs above preliminary RELs was excavated and disposed of at a Subtitle C landfill. Confirmation sampling was conducted to confirm the final extent of the excavation areas.
- The SER treatment system was demobilized in spring 2012.
- Wells and monitoring points used during the SER were decommissioned. In addition, monitoring wells not used for POC monitoring were decommissioned.
- All soils are to be capped with a minimum of 2 feet of soil and a geotextile (i.e., a permeable cap) or an equivalent exposure barrier (e.g., liner, asphalt, concrete, building). Work in the area to be capped includes grading and capping the steeply sloped bank above ordinary high water to address bank erosion issues. This work is in progress.
- The existing stormwater system was removed and a new stormwater system incorporating engineering controls was installed.
- Institutional controls, an LRIS-wide SMP, and a cap maintenance plan will be implemented as part of the interim action for the LRIS.

The interim actions begun in Cells 1 and 2 during the summer and fall of 2012, which are to be completed in 2013, are consistent with the remedy described above. A construction completion report documenting the soil excavation and consolidation, construction of the engineered cap, and institutional controls is being prepared for submittal to Ecology.

11.1.1.2 Cells 3 and 4

The Cells 3 and 4 interim remedial actions were completed in 2010 and 2011 and involved the following remedial action elements:

- Soil exceeding the preliminary RELs was excavated and disposed of at a Subtitle C landfill. Confirmation sampling was conducted to confirm the final extent of the excavation areas.
- All soils were capped with a minimum of 2 feet of soil and a geotextile (i.e., a permeable cap).
- The existing stormwater system was removed and a new stormwater system incorporating engineering controls was installed.
- All structures, such as bulkhead, barge loading ramp, building, pilings, railroad tracks, and pavement, were removed.
- Monitoring wells not used for POC monitoring were decommissioned.

Institutional controls, an LRIS-wide SMP, and a cap maintenance plan will be implemented as part of the interim action for the LRIS.

The interim actions completed in Cells 3 and 4 during the summer and fall of 2010/2011 are consistent with the remedy described above. A construction completion report documenting the soil excavation and consolidation, construction of the engineered cap, and institutional controls is being prepared for submittal to Ecology.

11.1.2 Port-owned Properties

As presented in Section 8, Alternative 2 (Engineered Cap) is protective of both human health and the environment and complies with MTCA requirements and Ecology expectations. Alternative 2 is effective without being disproportionately costly and is identified as the preferred alternative to be implemented at the Port-owned Railroad Avenue site. Soil at this site does not exceed the $1x10^{-5}$ cumulative carcinogenic risk level.

The following is a summary of the recommended remedial alternative components:

- Placement of a 2-foot cap at the Port Railroad Avenue properties to mitigate ecological exposure to dioxins.
- The extent of the cap would include a portion of the Port-owned property and the City right-of-way, approximately 0.55 acres.
- For constructability, the entire site would receive a gravel operation surface and may require limited regarding, with the possible addition of a retaining wall.
- Annual cap monitoring and development of a site management plan.

11.2 Groundwater

The SER system treated the source area from 2004 through 2011. Steam was injected in the entire SER treatment area (Areas 1 through 4) to remove mobile contaminants from groundwater and the vadose zone. Active steam injection was shut down on June 30, 2011, after completion of Phase 1 (conduct pilot study), Phase 2 (complete treatment), and the polish stage (confirm diminishing returns). The groundwater and vapor extraction and treatment systems operated until October 2011 to reduce subsurface temperatures and capture chemicals that had been mobilized by the heat. Cleanout and demolition of the system began in November 2011 and was completed in May 2012, consistent with the final closure plan (Port and Ecology, 2012). The closure was certified by MFA in October 2012 and was approved by Ecology (Appendix A).

In Cells 1, 2, and 3 and the southern portion of the RNWR (i.e., Carty Unit), groundwater monitoring will be completed at existing monitoring wells defined as conditional POCs to assess natural contaminant attenuation rates and to verify that groundwater concentrations are stable or declining. Groundwater modeling indicates that current groundwater conditions will not adversely impact surface waters near the Site. Institutional controls preventing consumption of groundwater will be implemented.

In Cell 4, no IHSs were detected in groundwater above CULs; therefore, no remedial actions were identified for groundwater in Cell 4.

11.3 Sediment

11.3.1 Lake River

Alternative 4 (Dredge and ENR) is identified as the preferred in-water remediation alternative for the Lake River sediment. It is identified as the most protective of human health and the environment for the following reasons:

- Dioxin TEQ areawide concentrations will be significantly reduced to the extent technically feasible; subsequent natural attenuation is expected to achieve the CUL of 5 ng/kg.
- Dioxin congener areawide concentrations will be below CULs protective of ecological receptors.
- Dioxin TEQ sediment concentrations will be below the CUL protective against direct contact and incidental ingestion by recreational users.
- Other contaminants exceeding screening levels (i.e., TPAH, PCP, and m&p-cresol) will be removed.
- Contaminated dredged sediment will be permanently removed and will not be available for potential future exposure or transport.
- Residuals within the dredge footprint and sediment with slightly elevated dioxin concentrations adjacent to the dredge footprint will be managed through the placement of an ENR layer.
- Alternative 4 provides the highest degree of certainty for long-term protectiveness, combined with immediate short-term reductions in surface concentrations, and is proportionately cost effective when the benefits are considered. Alternatives 1 (MNR)

and 2 (EMNR) provide marginal levels of protectiveness over the short and long terms because high concentrations would remain in place. Alternative 3 (Sediment Cap) achieves a level of protectiveness similar to that of Alternative 4, with a similar level of disturbance to sediments and with a similar cost, while leaving high contaminant concentrations in place.

- Alternative 4 does not constrain future site uses or hinder dredging of the navigation channel, although evaluation of sediment conditions would be required before activities involving significant sediment disturbance are initiated.

The following is a summary of the recommended remedial alternative components:

- Dredge removal of Lake River sediment with dioxin TEQ exceeding 30 ng/kg. The extent of the dredge area will be refined during design. Dredging would also remove other contaminants above screening levels.
- ENR would be used in the dredged area and in undredged areas between 5 ng/kg and 30 ng/kg dioxin TEQ.
- Dredged material would be disposed of as nonhazardous material waste at a Subtitle D landfill facility. The dredged material would not be designated as either a RCRA-listed hazardous waste or a RCRA characteristic waste.
- Bank armor would be applied to stabilize the lower portions of the bank, which is currently not addressed by the upland interim remedial actions. The armor would be tied into the bank layback and extend down to overlap the dredged areas and the ENR layer. The armor would also act to tie in the upland cap, protecting against direct contact and erosion of bank soil.
- Before the start of dredge operations, remnants of historical infrastructure would be removed, including dolphins, pilings, and a dock (currently in operation).
- Best management practices for water quality would be considered and implemented during work; these may include silt curtains for containment; dredge methods; and turbidity monitoring before, during, and after construction.
- Natural recovery would be monitored.

11.3.2 Carty Lake

Alternative 2 (Focused Dredge and Limited Residuals Cap) is the preferred alternative. This alternative is found to be the most protective of human health and the environment relative to cost for the following reasons:

- Sediment with concentrations of dioxins above CULs protective of ecological receptors would be removed.
- Areawide dioxin concentrations would be significantly reduced, as all sediment exceeding 100 ng/kg dioxin TEQ would be removed.

- Dredging impacted dioxin areas would also remove all other contaminants above screening criteria.
- Sediment with the highest concentrations of dioxins would be permanently removed and would not be available for potential future exposure or transport.
- Carty Lake is not a significant fishing resource; institutional controls would be applied to continue to limit consumption of fish from Carty Lake.
- Residuals within the dredge footprint would be managed through the placement of a thin sand cap layer.
- Alternative 2 provides the appropriate level of long-term protectiveness and certainty. Alternative 1 (MNR) provides limited protectiveness only over the very long term, provided that natural deposition and mixing are occurring, which has not been verified. Alternative 3 costs nearly half again as much as Alternative 2 and results in nearly the same postremedial sediment concentrations. Alternative 4 (Focused Dredge and Full Residuals Cap) does achieve a very high level of protectiveness, but at significant additional cost and negative impact to the existing ecosystem of the lake.
- Alternative 2 would be implemented with appropriate institutional controls, including advisories on fish consumption to protect human health.

The following summarizes the recommended alternative components:

- Dredging and disposal of approximately 5,650 CY of lake sediment above RELs in the southern portion of the lake. The extent of the dredge area will be refined during design, in consultation with USFWS.
- Approximately 2,700 CY of sand for a residuals cap would be placed in a 6- to 12-inch-thick layer over dredged areas and the resulting residuals that are assumed to be contained within the dredge footprint.
- Dredged material would be disposed of as nonhazardous material waste at a Subtitle D landfill facility. The dredged material would not be designated as either a RCRA-listed hazardous waste or a RCRA characteristic waste.
- Best management practices for water quality would be implemented in the form of silt curtains for containment, as well as turbidity monitoring before, during, and after construction.
- Natural recovery would be monitored.
- Institutional controls to protect human receptors would be put into place. Advisories on fish consumption would be included as institutional controls.
- Additional evaluations may be necessary if the USFWS proceeds with plans to reconnect Carty Lake with Gee Creek. This action may change the fluvial environment and allow salmonids access to the lake.

LIMITATIONS

The services undertaken in completing this report were performed consistent with generally accepted professional consulting principles and practices. No other warranty, express or implied, is made. These services were performed consistent with our agreement with our client. This report is solely for the use and information of our client unless otherwise noted. Any reliance on this report by a third party is at such party's sole risk.

Opinions and recommendations contained in this report apply to conditions existing when services were performed and are intended only for the client, purposes, locations, time frames, and project parameters indicated. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations subsequent to performance of services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this report.

NOTES:

-- = not available or not applicable.

Air R = air rotary.

Becker = DR-24 air rotary.

Cable = cable tool.

ft bgs = feet below ground surface.

ft NGVD = feet National Geodetic Vertical Datum of 1927/1947.

HSA = hollow-stem auger.

ODEX = air rotary with ODEX underreamer.

Sonic = rotosonic.

*dense nonaqueous-phase liquid funnel installed at base of screened interval.

**open-ended casing; no screened interval.

NOTES:

Depth to bottom measurements are historical, except when DNAPL is checked for in wells.

WLE are corrected for LNAPL by the following formula:

Corrected WLE = (LNAPL thickness x 0.98) + (TOC - Depth to water).

0.98 equals the approximate specific gravity [dimensionless] of the LNAPL.

-- = not measured.

DNAPL = dense nonaqueous-phase liquid.

ft = feet.

LNAPL = light nonaqueous-phase liquid.

NA = not available.

NGVD = National Geodetic Vertical Datum of 1927/1947.

NP = not present.

TOC = top of casing.

WLE = water level elevations.

[a] Water level collected during approximate low tide.

[b] Water level collected during approximate high tide.

[c] Monitoring wells were modified as a result of Cell 3 interim actions.

[d] Monitoring well monument was repaired and additional well casing was added to top of well.

NOTES:

Difference in Hydraulic Head

Positive numbers represent a downward flow of groundwater.

Negative numbers represent an upward flow of groundwater.

D = Monitoring well screened in the deep portion of the UWBZ.

ft = feet.

NGVD = National Geodetic Vertical Datum of 1927/1947.

S = Monitoring well screened in the shallow portion of the UWBZ.

UWBZ = upper water-bearing zone.

WLE = water level elevation.

NOTES:

Difference in Hydraulic Head

Positive numbers represent a downward flow of groundwater.

Negative numbers represent an upward flow of groundwater.

D = Monitoring well screened in the deep portion of the UWBZ.

ft = feet.

LWBZ = lower water-bearing zone.

NGVD = National Geodetic Vertical Datum of 1927/1947.

UWBZ = upper water-bearing zone.

WLE = water level elevation.

NOTES:

Difference in Hydraulic Head

Positive numbers represent a downward flow of groundwater.

Negative numbers represent an upward flow of groundwater.

D = Monitoring well screened in the deep portion of the UWBZ.

ft = feet.

LWBZ = lower water-bearing zone.

NGVD = National Geodetic Vertical Datum of 1927/1947.

UWBZ = upper water-bearing zone.

WLE = water level elevation.

NOTES:

D = Monitoring well screened in the deep portion of the WBZ.

ft = feet.

LWBZ = lower water-bearing zone.

NA = not available.

NGVD = National Geodetic Vertical Datum of 1927/1947.

S = Monitoring well screened in the shallow portion of the WBZ.

UWBZ = upper water-bearing zone.

WBZ = water-bearing zone

[a] Surface water elevations used from Lake River (low value) and Carty Lake as indicated. The lower water elevation of the two Lake River measurements was used for the comparison.

[b] Water levels obtained during low tide conditions.

[c] Water levels obtained during high tide conditions.

--	B-52	CELL 42-S-3.5	11/20/1997	3.5	**101**

NOTES:

Bold numbers indicate values that exceed MTCA Method B or applicable screening levels.

Highlighted numbers indicate values that exceed MTCA Method C CULs.

-- = Does not apply.

CUL = cleanup level.

ft. bgs = feet below ground surface.

mg/kg = milligrams per kilogram.

MTCA = Washington State Department of Ecology's Model Toxics Control Act.

SER = steam-enhanced remediation.

*CUL for arsenic is the 90th Percentile Background Concentration for Clark County, since it is greater than the Method B CUL.

NOTES:

Bold numbers indicate values that exceed MTCA Method B or applicable screening levels. If values were non-detects ("U"), 1/2 the reported concentration was compared with the screening level.

Highlighted numbers indicate values that exceed MTCA Method C CULs. If values were non-detects ("U"), 1/2 the reported concentration was compared with the screening level.

-- = Does not apply.

cPAH = carcinogenic PAH.

CUL = cleanup level.

ft. bgs = feet below ground surface.

MTCA = Washington State Department of Ecology's Model Toxics Control Act.

µg/kg = micrograms per kilogram.

NA = not available.

NV = no value.

PAH = polycyclic aromatic hydrocarbon.

SER = steam-enhanced remediation.

TEQ = toxicity equivalent.

U = Not detected at or above the shown method reporting limit. 1/2 the value was applied in calculating cPAH TEQ.

NOTES:

Bold indicates values that exceed MTCA Method B Soil CUL; if values were non-detects ("U"), 1/2 the reported concentration was compared with the MTCA Method B Soil CUL. Estimated values were compared with MTCA Method B Soil CUL.

Total PAH includes the following PAHs: naphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, anthracene, 2-methylnaphthalene 1-methylnaphthalene (if available), fluoranthene, pyrene, benzo(a)anthracene, chrysene, total benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene.

Total SMS HPAH (High PAH) is the total of fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene and benzo(g,h,i)perylene (2-methylnaphthalene is not included).

Total Dioxins is the sum of the homologues—OCDF, OCDD, HpCDF, HpCDD, HxCDF, HxCDD, PeCDF, PeCDD, TCDF, and TCDD.

bgs = below ground surface.

cPAH = carcinogenic PAH.

CUL = cleanup level.

Dup = duplicate sample.

J = Estimated value. Value used in calculations.

mg/kg = milligrams per kilogram.

MTCA = Model Toxics Control Act.

µg/kg = micrograms per kilogram.

ng/kg = nanograms per kilogram.

NV = no value.

Port = Port of Ridgefield.

RNWR = Ridgefield National Wildlife Refuge.

TEQ = toxicity equivalent.

U = Not detected. 1/2 the reported concentration used in dioxin TEQ and Total PAH calculations.

NOTES:

During sampling event, samples from MW-38, MW-39, MW-45D, and MW-57D will be duplicated.

As = arsenic.

Cr = chromium.

Cu = copper.

M = Monitoring well sampled approximately every 18 months (alternating between January and August) to monitor seasonal variations .

NWTPH-Dx = Semivolatile Petroleum Products Method for Soil and Water

PCE = tetrachloroethene.

PCP = pentachlorophenol.

S = Monitoring well sampled semiannually in January and August.

SVOC = semivolatile organic compound.

USEPA = U.S. Environmental Protection Agency.

VOC = volatile organic compound.

Zn = zinc.

NOTES:

During sampling event, samples from MW-45D and MW-57D will be duplicated.

only = Only wells with consistent indicator hazardous substance (IHS) detections will be analyzed for those specific IHSs, such as PCE or PCP. Note that some of the groundwater samples may have detected other IHSs in past sampling (i.e., before steam-enhanced remediation system operation) or only infrequently.

PCP = pentachlorophenol.

PCE = tetrachloroethene.

POC = point of compliance.

SVOC = semivolatile organic compound.

USEPA = U.S. Environmental Protection Agency.

VOC = volatile organic compound.

x = Indicates that the action or analysis is to be conducted during each monitoring event.

[a] Groundwater samples for at least the first two sampling events from MW-63 will also be analyzed for petroleum hydrocarbons, using NWTPH-Dx.

NOTES:

-- = not analyzed or not Cell 3 point of compliance monitoring results.

B = analyte found in the associated method blank.

Bold = detected concentration that exceeds MTCA Method B Groundwater Cleanup Level. Non-detect values ("U" or "UJ") were not compared with MTCA Method B Groundwater Cleanup Level.

dup = duplicate sample.

LWBZ = lower water-bearing zone.

MTCA = Model Toxics Control Act.

μg/L = micrograms per liter.

NS = not sampled.

NV = no value.

RNWR = Ridgefield National Wildlife Refuge.

U = not detected at or above method reporting limit.

UJ = not detected above estimated detection limit.

UWBZ = upper water-bearing zone.

[a] m-xylene.

[b] Volatile organic compound and dissolved metal data for October 29, 2004 were switched because of mislabeling during sampling.

Table 3-9
Semivolatile Organic Compounds in Groundwater—Cells 1 and 2 and RNWR (µg/L)
Former PWT Site RI/FS

NOTES:

-- = not analyzed or not Cell 3 point of compliance monitoring results.

Bold = detected concentration that exceeds MTCA Method B Groundwater Cleanup Level. non-detect values ("U," "UJ" or "UR") were not compared with MTCA Method B Groundwater Cleanup Level; estimated values ("J") were.

B = analyte found in the associated method blank.

cPAH = carcinogenic PAH.

dup = duplicate sample.

J = Estimated value. Value used in calculations.

LWBZ = lower water-bearing zone.

MTCA = Model Toxics Control Act.

µg/L = micrograms per liter.

ND = no cPAH detections.

NS = not sampled.

NV = no value.

PAH = polycyclic aromatic hydrocarbon.

RNWR = Ridgefield National Wildlife Refuge.

TEQ = toxicity equivalent, calculated using toxicity equivalent factors, consistent with Washington Administrative Code 173-340-900.

U = Not detected at or above method reporting limit. Half the value used in calculations.

UJ = not detected above estimated detection limit. Half the value used in calculations.

UR = Data were rejected because of poor laboratory surrogate recoveries. Cannot be used in calculations.

UWBZ = upper water-bearing zone.

[a] Semivolatile organic compounds data for July 20, 2005, were switched because of mislabeling during sampling.

NOTES:

Bold = detected concentration that exceeds MTCA Method B groundwater cleanup level. non-detect values ("U") were not compared with MTCA Method B groundwater cleanup level.

dup = duplicate sample.

LWBZ = lower water-bearing zone.

MTCA = Model Toxics Control Act.

µg/L = micrograms per liter.

NS = not sampled.

RNWR = Ridgefield National Wildlife Refuge.

UWBZ = upper water-bearing zone.

U = not detected at or above method reporting limit.

[a] MTCA Method A CUL listed for arsenic, which is representative of background conditions.

[b] Hexavalent chromium screening criteria.

[c] Samples were switched because of mislabeling.

	09/02/2011	MW61090211	0.0773 U	0.193 U

NOTES:

Bold = detected concentration that exceeds MTCA Method A Groundwater Cleanup Level. non-detect values ("U") were not compared with MTCA Method B groundwater cleanup level.

dup = duplicate sample
LWBZ = lower water-bearing zone.
mg/L = milligrams per kilogram.
MTCA = Model Toxics Control Act.
NS = not sampled.
RNWR = Ridgefield National Wildlife Refuge.
U = not detected at or above method reporting limit.
UWBZ = upper water-bearing zone.

NOTES:

CUL = cleanup level.

dup = duplicate sample.

HpCDD = heptachloro dibenzo-p-dioxin.

HpCDF = heptachloro dibenzofuran.

HxCDD = hexachloro dibenzo-p-dioxin.

HxCDF = hexachloro dibenzofuran.

J = estimated value.

MTCA = Washington State Department of Ecology's Model Toxics Control Act.

NV = no value.

OCDD = octachloro dibenzo-p-dioxin.

OCDF = octachloro dibenzofuran.

PeCDD = pentachloro dibenzo-p-dioxin.

PeCDF = pentachloro dibenzofuran.

pg/L = picograms per liter.

RNWR = Ridgefield National Wildlife Refuge.

TEQ = toxicity equivalent.

TCDD = tetrachloro dibenzo-p-dioxin.

TCDF = tetrachloro dibenzofuran.

U = not detected at or above method reporting limit.

UJ = not detected above estimated detection limit.

NOTES:

Bold number indicates a detected concentration that exceeds one or more of its screening criteria.

-- = not available.

CUL = cleanup level.

MTCA = Washington State Department of Ecology's Model Toxics Control Act.

µg/L = micrograms per liter.

NS = not sampled.

U = not detected at or above method reporting limit.

UWBZ = upper water-bearing zone.

[a] MTCA Method A CUL.

[b] Hexavalent chromium screening criteria.

NOTES:

Bold number indicates a detected concentration that exceeds one or more of its screening criteria.

-- = not available.

cPAH = carcinogenic polycyclic aromatic hydrocarbon.

CUL = cleanup level.

J = analyte was positively identified; associated numerical value is approximate concentration of analyte in sample.

MTCA = Washington State Department of Ecology's Model Toxics Control Act.

µg/L = micrograms per liter.

ND = not detected.

NS = not sampled.

NV = no value.

PAH = polycyclic aromatic hydrocarbon.

U = not detected at or above method reporting limit.

UWBZ = upper water-bearing zone.

NOTES:
Bold number indicates a detected concentration that exceeds one or more of its screening criteria.
-- = not available.
CUL = cleanup level.
J = analyte was positively identified; associated numerical value is approximate concentration of analyte in sample.
MTCA = Washington State Department of Ecology's Model Toxics Control Act.
µg/L = micrograms per liter.
NS = not sampled.
NV = no value.
U = not detected at or above method reporting limit.
UWBZ = upper water-bearing zone.
[a] 1,3-Dichloropropene screening criteria.
[b] m-Xylenes screening criteria.

NOTES:

Bold number indicates a detected concentration that exceeds one or more of its screening criteria.

CUL = cleanup level.

MTCA = Washington State Department of Ecology's Model Toxics Control Act.

µg/L = micrograms per liter.

NS = not sampled.

U = not detected at or above method reporting limit.

UWBZ = upper water-bearing zone.

-- = not analyzed.
Bold results exceed one or more of the screening criteria. non-detect values ("U") were not compared with screening criteria.
CCC = criterion continuous concentration.
CUL = cleanup level.
HH = human health.
MTCA = Model Toxics Control Act.
µg/L = micrograms per liter.
ND = not detected.
NV = no value.
U = not detected at or above method reporting limit.
USEPA = U.S. Environmental Protection Agency.
WQC = water quality criteria.

[a] Hexavalent chromium value.

[b] Trivalent chromium value.

[c] Based on MTCA Method A groundwater CUL based on background concentration in the state of Washington.

[d] Based on USEPA maximum contaminant level.

Former PWT Site RI/FS

NOTES:

Bold indicates values that exceed screening criteria; if values were non-detects ("U" or "UJ"), 1/2 the reported concentration was compared with screening criteria. Estimated values were compared with the screening criteria.

Total HPAH (high PAH) is the total of fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene.

Total LPAH (low PAH) is the total of naphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, anthracene, and 2-methylnaphthalene.

Total PAH includes the following PAHs: naphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, anthracene, 2-methylnaphthalene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, total benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene.

Total PCB Aroclors is the sum of the individual Aroclors. If no Aroclors were detected, the total is reported as non-detect (U) at the detection limit of the individual Aroclors.

cm = centimeter(s).

DEQ = Oregon Department of Environmental Quality.

J = Estimated value. Reported concentration used in dioxin TEQ and Total PAH calculations calculations.

mg/kg = milligrams per kilogram.

µg/kg = micrograms per kilogram.

ng/kg = nanograms per kilogram.

NV = no value.

TEQ = toxicity equivalent.

U = Not detected. 1/2 the reported concentration used in dioxin TEQ and Total PAH calculations.

UJ = Not detected. The reported value is estimated. 1/2 the reported concentration used in dioxin TEQ and Total PAH calculations.

[a] Avocet 2011 freshwater sediment benthic screening criteria.

[b] McDonald et al. (2000) probable effect concentration values developed for predicting sediment toxicity.

[c] Values represent the default value protective of bird, freshwater fish, and mammal populations (DEQ 2007).

[d] Pentachlorophenol value based on DEQ (2007) human fish consumption screening level value; dioxin TEQ based on natural background; see Appendix K for derivation.

[e] Represents criteria for 4-methylphenol.

Table 3-19
Lake River Subsurface Sediment Screening Results
Former PWT Site RI/FS

NOTES:

Bold indicates values that exceed screening criteria; if values were non-detects ("U" or "UJ"), 1/2 the reported concentration was compared with screening criteria. Estimated values were compared with the screening criteria.

Total HPAH (high PAH) is the total of fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene.

Total LPAH (low PAH) is the total of naphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, anthracene, and 2-methylnaphthalene.

Total PAH includes the following PAHs: naphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, anthracene, 2-methylnaphthalene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, total benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene.

DEQ = Oregon Department of Environmental Quality.

ft = foot/feet.

J = Estimated value. Reported concentration used in dioxin TEQ and Total PAH calculations calculations.

mg/kg = milligrams per kilogram.

µg/kg = micrograms per kilogram.

ng/kg = nanograms per kilogram.

NV = no value.

TEQ = toxicity equivalent.

U = Not detected. 1/2 the reported concentration used in dioxin TEQ and Total PAH calculations.

UJ = Not detected. The reported value is estimated. 1/2 the reported concentration used in dioxin TEQ and Total PAH calculations.

[a] Avocet 2011 freshwater sediment benthic screening criteria.

[b] McDonald et al. (2000) probable effect concentration values developed for predicting sediment toxicity.

[c] Values represent the default value protective of bird, freshwater fish, and mammal populations (DEQ 2007).

[d] Pentachlorophenol value based on DEQ (2007) human fish consumption screening level value; dioxin TEQ based on natural background; see Appendix K for derivation.

[e] Represents criteria for 4-methylphenol.

NOTES:

Bold indicates values that exceed screening criteria; if values were non-detects ("U" or "UJ"), 1/2 the reported concentration was compared with screening criteria. Estimated values were compared with the screening criteria.

Total HPAH (high PAH) is the total of fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene.

Total LPAH (low PAH) is the total of naphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, anthracene, and 2-methylnaphthalene.

Total PAH includes the following PAHs: naphthalene, acenaphthylene, acenaphthene, fluorene, phenanthrene, anthracene, 2-methylnaphthalene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, total benzofluoranthenes, benzo(a)pyrene, indeno(1,2,3-c,d)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene.

cm = centimeter(s).

DEQ = Oregon Department of Environmental Quality.

ft = feet.

J = Estimated value. Reported concentration used in dioxin TEQ and Total PAH calculations calculations.

mg/kg = milligrams per kilogram.

µg/kg = micrograms per kilogram.

ng/kg = nanograms per kilogram.

NV = no value.

TEQ = toxicity equivalent.

U = Not detected. 1/2 the reported concentration used in dioxin TEQ and Total PAH calculations.

UJ = Not detected. The reported value is estimated. 1/2 the reported concentration used in dioxin TEQ and Total PAH calculations.

[a] Avocet 2011 freshwater sediment benthic screening criteria.

[b] McDonald et al. (2000) probable effect concentration values developed for predicting sediment toxicity.

[c] Values represent the default value protective of bird, freshwater fish, and mammal populations (DEQ 2007).

[d] Pentachlorophenol value based on DEQ (2007) human fish consumption screening level value; dioxin TEQ based on natural background; see Appendix K for derivation.

[e] Represents criteria for 4-methylphenol.

NOTES:

Model Run A and B refer to the two model runs necessary to complete the modeling.

Regulatory criteria are based on most stringent available surface water[b] or groundwater[c] criteria. Pentachlorophenol, tetrachloroethene, arsenic, dibenzofuran, bis(2-ethylhexyl) phthalate, and chromium are based on U.S. Environmental Protection Agency water quality criteria for consumption of organisms and water. However, the Washington State Department of Ecology lists the background concentration of arsenic[d] in groundwater at 0.005 mg/L.

Constants used in the modeling are:

– Hydraulic gradient of 0.018.

– Soil bulk density of 1.6 kilograms per liter.

– Effective porosity of 0.3.

< 0.001 = Model does not calculate numbers less than 0.0005 mg/L.

cm/sec = centimeter(s) per second.

FOC = fraction of organic carbon.

L/kg = liters per kilogram.

mg/L = milligrams per liter.

NA = not applicable.

[a] The distribution coefficient was used for arsenic.

[b] Most stringent available surface water criteria.

[c] Most stringent available groundwater criteria.

[d] Background concentration of arsenic.

Table 6-1

NOTES:

Source: exported from CLARC database (Ecology, 2011).

a = Washington State Department of Ecology Publication No. 94-115, Natural Background Soil Metals Concentrations in Washington State, Clark County.

b = MTCA Ecological Indicator Concentration for protection of wildlife (Table 749-3).

BEHP = bis(2-ethylhexyl) phthalate.

c = MTCA Method B, direct contact (ingestion only), unrestricted land use.

CLARC = Cleanup levels and risk calculation

cPAH TEQ = carcinogenic PAH toxicity equivalent.

d = not an indicator hazardous substance in specified media.

Dioxin TEQ = chlorinated dibenzo-p-dioxins and dibenzofurans toxicity equivalent.

DRO = diesel-range organics.

e = MTCA Method A Industrial/Unrestricted Land Use Table Value.

f = MTCA Method A groundwater cleanup level.

MCLw = Washington State maximum contaminant level goal.

g = MTCA Method B groundwater cleanup level.

GRO = gasoline-range organics.

h = MTCA Method B groundwater screening level for vapor intrusion pathway; values used if MTCA Method A or B groundwater cleanup levels were unavailable during remedial investigation or interim action activities.

mg/kg = milligrams per kilogram.

MTCA = Model Toxics Control Act.

µg/L = micrograms per liter.

PAH = polycyclic aromatic hydrocarbon.

NA = not applicable.

RRO = residual-range organics.

TCE = trichloroethene.

SVOC = semivolatile organic compound.

VOC = volatile organic compound.

Table 6-2
Summary of Preliminary Port-Owned Properties Cleanup Levels
Former PWT Site RI/FS

Furan TEQ[a]	NA	1.14E+01	NA	1.14E+01

NOTES:

CUL = cleanup level.

MTCA = Model Toxics Control Act.

NA = not applicable.

ng/kg = nanograms per kilogram.

TEQ = toxicity equivalent.

[a] Ecological CULs are derived separately for dioxin congeners and for furan congeners, as determined in coordination with Washington State Department of Ecology (see Appendix B for derivation of TEQs).

NOTES:

Risk-based CULs are based on standard, default assumptions commonly used and in rule, when available. Limited site-specific assumptions, where applicable, are integrated into CUL models, although models developed do no represent refined site-specific risk analyses.

Salmon, Mink, and Heron were receptors for fish, mammal, and bird models, respectively.

CUL = cleanup level.

HpCDD = heptachloro dibenzo-p-dioxin.

HpCDF = heptachloro dibenzofuran.

HxCDD = hexachloro dibenzo-p-dioxin.

HxCDF = hexachloro dibenzofuran.

NA = not applicable.

ng/kg = nanograms per kilogram.

OCDD = octachloro dibenzo-p-dioxin.

OCDF = octachloro dibenzofuran.

PeCDD = pentachloro dibenzo-p-dioxin.

PeCDF = pentachloro dibenzofuran.

PQL = practical quantitation limit.

TCDD = tetrachloro dibenzo-p-dioxin.

TCDF = tetrachloro dibenzofuran.

TEQ = toxicity equivalent.

NOTES:

Bold indicates values that exceed CULs; if values were non-detects ("U" or "UJ"), half the reported concentration was compared with CULs. Estimated values were compared with the screening criteria.

cm = centimeter(s).
ft = feet.
HpCDD = heptachlorodibenzo-p-dioxin.
HpCDF = heptachlorodibenzofuran.
HxCDF = hexachlorodibenzofuran.
J = estimated value.
ng/kg = nanograms per kilogram.
NV = no value.
OCDD = octachlorodibenzo-p-dioxin.
OCDF = octachlorodibenzofuran.
PeCDD = pentachlorodibenzo-p-dioxin.
PeCDF = pentachlorodibenzofuran.
TCDD = tetrachlorodibenzo-p-dioxin.
TCDF = tetrachlorodibenzofuran.
TEQ = Toxicity equivalent.
U = Compound analyzed, but not detected above detection limit. Half the value used in calculations.
UJ = Compound analyzed, but not detected above estimated detection limit. Half the value used in calculations.

Table 6-5
Summary of Preliminary Carty Lake Cleanup Levels
Former PWT Site RI/FS

NOTES:

Risk-based CULs are based on standard, default assumptions commonly used and in rule, when available. Limited site-specific assumptions, where applicable, are integrated into CUL models, although models developed do no represent refined site-specific risk analyses.

Salmon, mink, and heron were receptors for fish, mammal, and bird models, respectively.

CUL = cleanup level.

HpCDD = heptachloro dibenzo-p-dioxin.

HpCDF = heptachloro dibenzofuran.

HxCDD = hexachloro dibenzo-p-dioxin.

HxCDF = hexachloro dibenzofuran.

NA = not applicable.

ng/kg = nanograms per kilogram.

OCDD = octachloro dibenzo-p-dioxin.

OCDF = octachloro dibenzofuran.

PeCDD = pentachloro dibenzo-p-dioxin.

PeCDF = pentachloro dibenzofuran.

PQL = practical quantitation limit.

REL = Remediation level

TCDF = tetrachloro dibenzofuran.

TEQ = toxicity equivalent.

[a] Based on restoration worker scenario; see text for details.

NOTES:

Bold indicates values that exceed CULs; if values were non-detects ("U" or "UJ"), half the reported concentration was compared with CULs. Estimated values were compared with the screening criteria.

cm = centimeter(s).

ft = feet.

HpCDD = heptachlorodibenzo-p-dioxin.

HpCDF = heptachlorodibenzofuran.

HxCDF = hexachlorodibenzofuran.

J = Estimated value.

ng/kg = nanograms per kilogram.

NV = no value.

OCDD = octachlorodibenzo-p-dioxin.

OCDF = octachlorodibenzofuran.

PeCDD = pentachlorodibenzo-p-dioxin.

PeCDF = pentachlorodibenzofuran.

TCDD = tetrachlorodibenzo-p-dioxin.

TCDF = tetrachlorodibenzofuran.

TEQ = toxicity equivalent.

U = Compound analyzed, but not detected above detection limit. Half the value used in calculations.

UJ = Compound analyzed, but not detected above estimated detection limit. Half the value used in calculations.

Table 7-1
Capping Sections
Former PWT Site RI/FS

Type of Use	Typical Section
Landscaping/green space	
<2 feet soil	Geotextile as demarcation; no landscaping; impermeable surface required (e.g., pavement, impermeable liner to prevent infiltration, buildings)
2 to 3 feet soil	Geotextile as demarcation layer; ground cover as outlined in the TEE (MFA, 2010a), gravel surfaces, or additional as approved by Ecology, any grasses
3 to 6 feet soil	Geotextile as demarcation layer; shrubs or trees as outlined in TEE (MFA, 2010a), gravel surfaces, or additional as approved by Ecology, any grasses
>6 feet soil	No geotextile and no vegetation planting restrictions
Parking	Impermeable surface (min. thickness 3 inches) with clean subbase as necessary for construction
Building/structure	Slab-on-grade (min. thickness 3 inches) with clean subbase as necessary for construction
Sidewalk/pathway	Impermeable surface (min. thickness 3 inches) with clean subbase as necessary for construction or gravel surface with minimum 2 feet clean fill

Table 8-1
Disproportionate Cost Analysis—Port-Owned Properties
Former PWT Site RI/FS

Alternative	Remedial Action	Protectiveness	Permanence	Long-term Effectiveness	Management of Short-term Risks	Technical and Admin. Implementability	Addresses Public Concerns	Sum	Total cost
1	Institutional Controls ▪ Deed restrictions, fence, and signs.	2	2	2	5	2	2	15	$53,000
2	Engineered Cap ▪ Gravel cap on Railroad Avenue property ▪ Site prep and regrading ▪ Post implementation cap monitoring	4	4	4	5	4	5	26	$184,000
3	Sampling and Removal ▪ Additional sampling of the property prior to final design ▪ Removal of soil to ecological CULs ▪ Placement of crushed rock for operational surface	5	5	5	2	3	4	24	$297,000

NOTES:

Criteria Scoring:

1—Does not satisfy the criterion.

2—Marginally satisfies the criterion.

3—Partially satisfies the criterion.

4—Mostly satisfies the criterion.

5—Completely satisfies the criterion.

CUL = cleanup level.

Table 9-1
Disproportionate Cost Analysis—Lake River
Former PWT Site RI/FS

Alternative	Remedial Action	Protectiveness	Permanence	Long-term Effectiveness	Mgmt of Short-term Risks	Technical and Admin. Implementability	Addresses Public Concerns	Sum	Total cost	Cost Effectiveness
1	Monitored Natural Recovery: ▪ Bank stabilization; ▪ Natural attenuation in the form of sedimentation; ▪ Multiple sampling events; ▪ Long-term monitoring plan; and ▪ Institutional controls.	2	2	2	5	2	5	18	$679,000	5
2	Enhanced Monitored Natural Recovery: ▪ Bank stabilization; ▪ Placement of a sand layer to enhance natural attenuation; ▪ Long-term monitoring plan; and ▪ Institutional controls.	3	3	3	4	2	5	20	$2,815,000	3
3	Engineered Cap: ▪ Bank stabilization; ▪ Placement of an engineered sand cap; ▪ Placement of a protective armor layer; ▪ Implementation of long-term monitoring and maintenance; and ▪ Institutional controls.	4	4	4	3	3	5	23	$7,718,000	2

Table 9-1
Disproportionate Cost Analysis—Lake River
Former PWT Site RI/FS

Alternative	Remedial Action	Protectiveness	Permanence	Long-term Effectiveness	Mgmt of Short-term Risks	Technical and Admin. Implementability	Addresses Public Concerns	Sum	Total cost	Cost Effectiveness
4	Dredging and ENR: ▪ Removal of impacted sediment through mechanical dredging; ▪ Existing in-water structure removal; ▪ Bank stabilization; and ▪ Placement of an ENR layer.	4	5	5	3	4	5	26	$9,492,000	2

NOTES:

Criteria Scoring:

1—Does not satisfy the criterion.

2—Marginally satisfies the criterion.

3—Partially satisfies the criterion.

4—Mostly satisfies the criterion.

5—Completely satisfies the criterion.

ENR = enhanced natural recovery.

Table 10-1
Disproportionate Cost Analysis—Carty Lake
Former PWT Site RI/FS

Alternative	Remedial Action	Protectiveness	Permanence	Long-term Effectiveness	Mgmt of Short-term Risks	Technical and Admin. Implementability	Addresses Public Concerns	Sum	Total cost	Cost Effectiveness
1	Monitored Natural Recovery: ▪ Natural attenuation; ▪ Multiple sampling events; ▪ Long-term monitoring plan; and ▪ Institutional controls to protect receptors.	2	1	2	5	2	3	15	$280,500	5
2	Focused Dredge and Limited Residuals Cap: ▪ Dredging the highly impacted southern area of Carty Lake; ▪ Placement of residuals cap layer over the dredged area; ▪ Post-remedy monitoring; and ▪ Institutional controls to protect receptors.	3	3	3	4	5	5	23	$1,633,000	4
3	Focused Dredge and Expanded Residuals Cap: ▪ Dredging the highly impacted southern area of Carty Lake and marginally impacted sediment; ▪ Placement of residuals cap layer over the dredged area; ▪ Post-remedy monitoring; and ▪ Institutional controls to protect receptors.	3	3	3	3	4	5	21	$2,308,000	3

▲ Staff Gauge

● Shallow UWBZ Monitoring Well

Equipotential Line (Contour Interval - 1.0 Foot)

12.04 Water Level Elevation in Feet (National Geodetic Vertical Datum [NGVD])

➡ Flow Direction

Notes:
1. The shallow Upper Water-Bearing Zone (UWBZ) potentiometric surface was constructed using monitoring wells screened between 15 feet NGVD and -5 feet NGVD.
2. Water level elevations from MW-16 and MW-17 were not used to construct the estimated potentiometric surface because they are completed above the UWBZ and are influenced by perched water.
3. Water level elevations from MW-7 were not used to construct the estimated potentiometric surface. MW-7 has been damaged by heat from the steam-enhanced remediation system and the water level is not consistent with past monitoring.

▨	Columbia Basalt	

■ Sample Interval

Notes:
1. MTCA = Model Toxics Control Act
2. CUL = cleanup level
3. ug/L = micrograms per liter
4. See Section 3 of the text for an explanation of the data and the kriging used to create this figure.
5. Although the kriging used to create this figure shows potential discharge to Lake River, numerical modeling indicates that arsenic does not discharge to surface water above CULs.
6. Data was collected in August 2011 (monitoring wells) and December 2011 (SER Area).
7. Reference Drawing 1 for well ID's.

5. ug/L = micrograms per liter
6. See Section 3 of the text for an explanation of the data and kriging used to create this figure.
7. Although the kriging used to create this figure shows potential discharge to Lake River, numerical modeling indicates that arsenic does not discharge to surface water above CULs.

To: Steve Taylor
Cc: Laurie Olin
Subject: SER Closure certification

Steve,
Thank you for the Certification of Clean Closure for the SER in the letter dated October 16, 2012.
Ecology considers the SER officially closed with this certification.
Craig

Re: Certification of Clean Closure for the Steam Enhanced Remediation System at the Port of Ridgefield, Lake River Industrial Site
Agreed Order No. 01TCPSR-3119

Dear Craig:

On behalf of the Port of Ridgefield (the Port), Maul Foster and Alongi, Inc. (MFA) has prepared this Certification of Clean Closure for the Port's steam enhanced remediation (SER) system.

On June 20, 2012, the Port submitted the *Final Closure Plan – Port of Ridgefield Steam Enhanced Remediation System* (Final Closure Plan). This letter is intended to satisfy section 3.9 of the Final Closure Plan that requires an independent qualified registered professional engineer familiar with SER operation to certify clean closure.

The SER system was utilized from March 2004 until June 2011 to remediate soil and groundwater impacts resulting from wood treating operations at the former Pacific Wood Treating Site. Port personnel decommissioned and cleaned the SER system between October 2011 and May 2012.

CERTIFICATION STATEMENT

It is my professional opinion that the SER system has been closed in accordance with the Final Closure Plan. This opinion is based on my familiarity with SER operation developed over the last 12 years, observations during closure, a review of closure records, and discussions with Port staff.

Sincerely,

Maul Foster & Alongi, Inc.

34036
EXPIRES: 3/30/14

Steven P. Taylor, PE
Principal Engineer

MANAGEMENT STATEMENT

As a manager at the Port of Ridgefield, I have reviewed the Final Closure Plan, and the Certification of Closure and believe that the SER system has been closed in accordance with the Final Closure Plan.

Brent Grening
Chief Executive Officer

FINAL CLOSURE PLAN PORT OF RIDGEFIELD STEAM ENHANCED REMEDIATION SYSTEM

Prepared for the Port of Ridgefield, Ridgefield, Washington
Prepared by Karl Jolin, P.E. Port of Ridgefield
and
Craig Rankine, RG, LHG, Department of Ecology
Report Date: June 20, 2012

FINAL CLOSURE PLAN
PORT OF RIDGEFIELD STEAM ENHANCED REMEDIATION SYSTEM

1.0 Introduction

This Closure Plan (Plan) is for clean closure of the Port of Ridgefield's (Port) steam-enhanced remediation (SER) system at the Port's Lake River Industrial Site (LRIS) in Ridgefield, Washington. The system is used to remove and treat free-phase wood treating compounds from the ground and groundwater at the former Pacific Wood Treating (PWT) Corporation. Closure of the system is required to prevent the release of dangerous materials contained by and within the system.

Except as noted herein this plan follows guidelines in the documents; *"Guidance for Clean Closure of Dangerous Waste Units and Facilities"* publication number 94-111, revised May 2005 and "*Closure Plan Template for Dangerous Waste Recyclers and Used Oil Processors*", publication number 05-04-006, May 2005. These documents were prepared by Washington State Department of Ecology (Ecology) Hazardous Waste and Toxics Reduction Program. This closure plan applies only to the well field piping and treatment plant process equipment. Other material such as below grade wells, dirt, concrete, asphalt or buildings are being decommissioned and demolished under Interim Actions required by Agreed Order 01TCPSR-3119 executed by the Ecology and the Port for work at the PWT site.

1.1 Facility Contact Information

- Laurie Olin, Director of Operations, 360-887-3873, lolin@portridgefield.org
- Craig Rankine, Ecology Site Manager/Hydrogeologist, 360-690-4795, cran461@ecy.wa.gov
- Karl Jolin, Project Manager, 360-772-2580, kjolin@portridgefield.org

The Port mailing address is PO Box 55, Ridgefield, WA 98642.
The site physical address is 111 West Division, Ridgefield, WA.

1.2 Facility description and information

The system consists of a well field containing steam injection wells, liquid and vapor extraction wells and connecting piping. The recovered liquid and vapor is routed through piping to the treatment plant. The SER process being used by the Port is based on steam flooding processes that have been used successfully in oil fields around the world. Essentially, steam is injected into the subsurface through a series of steam injection wells. As the heat is put in the ground, semi-volatile contaminants become volatile and are captured by vapor extraction wells; simultaneously, the viscosity of nonaqueous-phase liquids (NAPL) is lowered so that NAPL can be recovered through groundwater extraction wells.

Liquids are treated using heat exchangers, bulk oil/water separation, coagulation and flocculation, filtration and finally granular activated carbon (GAC). Vapors are treated using heat exchangers, bulk oil/liquid separators, dryers and finally GAC.

The Port has owned the property since September 27, 1943.

1.3 Facility History, Function, Location and Layout

For approximately 30 years, PWT treated wood on property owned by the Port. PWT used a variety of wood-treating chemicals, including creosote, pentachlorophenol (PCP), and water-borne solutions containing copper, chromium, and arsenic.

The SER system is located on paved and open bare flat ground covering approximately four acres at the former PWT industrial site (zone industrial) Port of Ridgefield. It has been in operation since March 3, 2004. The system is surrounded by open space and Port warehouse buildings. The facility arrangement and layout, including locations of the tent housing the SER treatment system and the adjacent well field, is shown on the attached Figure 1.

The dangerous waste identification number for the facility is WAD 009422411.

A summary of the waste, waste destinations (treatment facilities addresses) and treatment type can be seen on the attached Table POR SER Waste Removal. Treatment system flow diagram is provided on the attached Figure FS-1. NAPL is collected in T-11 tank and then transferred to T-6 before loading into a tank truck for shipment to be incinerated. Filtered sludge is removed from the filter press and stored in a shipping hopper until it can be scheduled for shipment to the landfill. Both vapor and liquid carbon is removed from their respective vessels under vacuum with dust collection and loaded into super sacks and are then shipped out for regeneration. Hazardous waste shipped from the treatment system goes out under waste code K-001 except liquid NAPL in tank T-6 which is listed as D-004, D-007, D-039, F-032, F-034, and F-035.

1.4 Product and Production Processes

NAPL contamination containing creosote, pentachlorophenol and copper chrome arsenate are removed from the subsurface strata via steam injection and subsequent vacuum extraction. There is a vapor system consisting of vacuum pumps, decant tanks and a vapor carbon system. The bulk of the contaminants in vapor end up on the carbon and are remove by steam stripping. The steam stripped contaminants are sent to a condenser then to a collection tank and then to a decant tank where they are separated from the condensed steam. The condensed steam is sent to the liquid system and the NAPL to the NAPL storage tank. The liquid system consists of a decant tank, equalization tank, chemical treatment tanks, clarifier, sludge tank, sand filters, liquid carbon vessels, clean water storage and chillers. The chillers cool the cleaned water prior to discharge to Lake River.

1.5 Dangerous Waste Management Units

The SER process consists of a single dangerous waste management unit. The sole purpose of this management unit is to remove aforementioned subsurface contamination, collect it, concentrate it and store liquid NAPL for incineration and filter press sludge for landfill disposal. An ancillary requirement necessitated by the treatment technology employed is to treat and purify a large volume of water that must be pumped from the ground in order to insure that ground water is not dispersed by the steam injection and thereby spread contamination.

1.6 Unit Description

The SER Process is comprised of a liquid and vapor system plus utilities that include compressed air, steam, electrical supply, cooling water and domestic water. Process equipment includes vessels, pumps, heat exchangers, sand filters, carbon adsorption vessels, instrumentation and miles of piping. Materials of construction are carbon steel with some fiberglass and a limited amount of plastic. Consult the attached figures and preceding descriptions for more details.

1.6.1 Maximum Waste Inventory

The NAPL tanks are capable of holding a total of 20,000 gallons and the maximum capacity for filter press sludge is 72,000 lbs.

2.0 Closure Performance Standard

The SER system will be closed in a manner that complies with the performance standard in WAC 173-303-610(2)(a) to achieve clean closure.
System removal:

- Will eliminate need for system maintenance.
- Will to the extent necessary protect human health and the environment and will control, minimize, or eliminate post-closure escape of dangerous waste or dangerous constituents.
- Will remove all waste and waste residues for proper disposal.
- Will remove tanks, containers, piping and other items used to recover and treat dangerous waste.

3.0 Closure Activities

Due to the unique circumstances of the overall system closure and to keep the upcoming site surface soil interim action work schedule intact, a number of the listed activities have been performed before the final version of this SER system Closure Plan was prepared.

3.1 Removal of Wastes and Waste Residues, Unit Parts, and Equipment, Piping and other Ancillary Equipment:

Once closure begins removal of wastes and waste residues will be accomplished by the following measures:

- Treatment of well field water and vapor extraction will cease.
- Because the entire well field was steamed again during the polish phase with a rental boiler there may be some equipment that will be difficult to steam that is obviously clean (as evidenced by lack of odor, etc.). In those particular cases and on a case by case basis if the evidence clearly indicates clean equipment it will be deemed clean.
- All of the well pumps will be removed from their respective wells. The pumps will be disassembled sufficient to be placed in a boiling water bath for decontamination. Pumps that can be salvaged will be rebuilt for sale or reuse elsewhere.

- Some pumps are stuck in their wells and in those cases the piping connections will be severed and the wells prepared for decommissioning.
- Cleanup will be conducted in phases, the well field first followed by the treatment system.
- The well field consists of six trunk systems, each will be cleaned separately; discharge water or condensate will be routed through the treatment system. It may be possible to make interconnections between some of the trunk systems and steam combinations. If this can be accomplished effectively some of the trunk systems will be steamed in tandem.
- The trunk systems have been color coded for easy identification in the field and on system figures and consist of the following: the outer well ring, the VT-1 liquid header, the VT-1 vapor header, the lower discharge lines from the QED air lift pumps, the upper discharge lines from the QED air lift pumps and finally the sucker tube header.
- Sludge removal is paramount and water movement through the system will be used where appropriate to move sludge through and from the well field and treatment system during cleaning.
- System flushing will be done first with City water at the combined rate of 40 gpm more or less introduced at the front of both the liquid and vapor systems T-18 and ET-1 (see system diagram on Figure 2).
- Cold city water will be processed for one week while all decant tanks and knock out pots are manually purged at least three times.
- After one week of flushing with cold city water, steam will be added to the city water producing hot water ≥ 100 °F at the front of both liquid and vapor systems. If it proves not to be practical to always maintain at least 100 F as near to it as possible will be maintained.
- Hot water will be processed for one week while simultaneously performing decant tank and knock out pot flushing multiple times during the week.
- Toward the end of the one week period of processing hot city water grab samples will be taken downstream of the major equipment in both the liquid and vapor systems for visual inspection. If oil sheens and noxious fumes are still in evidence more steam will be used to raise the water temperature to eliminate the oil sheens and noxious fumes. Grab samples will be used to assess time needed for hot water flushing.
- Flushing complete trunk sequences will be attempted to maximize cleaning effectiveness but due to system wear and corrosion adjustments will be needed on a case by case situation. Steam will be introduced into the liquid system piping and run backward through that piping towards each extraction well. A bridge will be installed between the liquid to the vapor piping lines bypassing the extraction wells. Discharge will be through the vapor system piping returning steam or condensate to the treatment system. Steam injection points and vapor removal points will be located such that all the piping and vessels including low points and dead ends (where practical) can be thoroughly purged with steam.

- A steam bath will be used for boiling small pipe pieces removed from trunk sections that are impractical to flow steam through. Vapors from the bath will be recovered and treated through the vacuum treatment system. Bath water can also be recovered and be treated through the liquid treatment system.
- The vapor removal points will be connected to the existing vapor system such that steam vented from the system being decontaminated is directed to the existing vapor treatment system. Thus this vented steam will be condensed and then scrubbed through the existing vapor carbon system. Therefore no contaminated steam used for decontamination will be vented directly to atmosphere. However, near completion of this operation the vapor system will be cleaned and at some point the carbon will be removed and the system will no longer function for contaminant removal. At that point only a diminimus amount of contaminants will remain and those contaminants will be steamed uncontrolled to atmosphere.
- Several steam headers with multiple valve connections will be installed within the process area in order to facilitate multiple purge steam connections throughout the process area. Conversely several vapor collection headers will be installed throughout the process area in order to facilitate directing the contaminated purge steam to the vapor treatment system. Liquid will collect in the existing vessels in both the liquid and the vapor systems and pumps associated with those vessels will be used to send the collected liquid to the liquid treatment system. Steam hoses will be used to route steam injection to the various steam injection points at upstream piping and inlets to vessels. Chemical resistant hoses will be used to route contaminated steam from downstream piping runs and vents from tanks to the vapor collection headers.
- The endeavor will be to steam the entire contaminated portion of the well field both liquid and vapor as a unit and in both directions (toward the inlet of the vapor and liquid systems and backwards into the injection and extraction wells). It will not be practical to steam the entire well field simultaneously. Several separate steaming operations will be necessary in order to accomplish this. Once the well field steaming is complete the entire decontaminated portion of the well field will either be blinded from or physically disconnected from the rest of the treatment system.
- Once the well field has been decontaminated and isolated from the rest of the system demobilization will begin.
- It should be noted that not only in the well field but also throughout the process the non contaminated utility piping (air, city water, etc.) will not be decontaminated simply because it has never been contaminated.
- The well field and the process will be steamed separately as two independent projects. The well field will be done first and then the process. Once the well field is done steaming multiple connections throughout the well field will be opened up. Flex-hoses will be removed and multiple flanges will be separated. The well field will then be examined as a unit. If there is no evidence of contamination in any of

these multiple connections then the well field will be deemed clean as a unit and the on-site crew will be tasked with disassembly.

- The liquid treatment system will be steamed from upstream to downstream until all of the liquid system prior to the media beds (sand & carbon) has been cleaned. Multiple steam injection points and multiple vapor collection points will be utilized as previously described above.
- Steam will be introduced simultaneously to the vapor system while the liquid system is being steamed (because the vapor system will be removing the steam introduced into the liquid system) such that contaminants are simultaneously removed from both the liquid and vapor systems. Knock out pots and decant tanks will be purged in both systems while this is going on. During this time period the treatment system may at times be operated on a batch basis due to insufficient water flow to operate continuously. Some days the system may be operated continuously and other days or at least part of days it may be down.
- Once both liquid and vapor systems are judged to be predominantly cleaned by assessing clarity of condensed steam in both systems a shutdown will be taken.
- Prior to shutdown samples of condensed steam (the only source of water for the liquid treatment system) will be sampled for compliance with the NPDES discharge permit. Sampling and analytical will be somewhat flexible: for example if grab samples have no odor indicating very clean condensate no analytical will be deemed necessary. But on the other hand if odors indicate the need for analytical work it may be done or the steaming continued until absence of odors indicate clean equipment.
- The purpose of the shutdown will be to open up the media beds (sand and carbon) for media removal. All media will be shipped out as K-001 hazardous waste.
- All media beds will be steamed thoroughly for multiple days with media intact. Once the media bed steaming has been completed the vessels will be opened up. If the vessel and the media look clean and smell clean both the media and the vessel will be deemed clean. All interconnecting piping on the media beds will be steamed individually. Steam will be directed to the vapor system.
- Once the media has been removed from the media beds the liquid treatment system will no longer function as designed and condensed steam sent to the liquid treatment system will have to be sampled for NPDES compliance prior to discharge to the river. In this manner cleanliness of the entire system will be judged.
- Once sampling confirms NPDES compliance with all sources of condensed steam (both vapor system and liquid system) the vapor system will also be shut down for carbon removal. Both carbon systems (vent control system and process system) will be opened up and carbon removed. All media will be shipped out as K-001 hazardous waste.

- Once the vapor carbon vessels are empty the secondary vapor carbon units will be shutdown and opened up for carbon removal.
- Upon secondary carbon removal the carbon will be shipped out as K-001 waste as well.
- Once the secondary vapor carbon units are emptied the entire POR SER treatment system will have been decontaminated.
- Any further decontamination will be conducted on individual pieces of equipment that fail inspection as noted during the deconstruction phase of the closure. Every attempt will be made to clean equipment before the treatment system is off-line.
- At this point the treatment system will no longer be functional and steaming or hot water boiling operations will be on equipment that cannot be judged to meet the "clean debris surface" criteria. A small amount of contaminants will go direct to atmosphere should this become necessary. However, since the entire system has been systematically cleaned any contaminants thus released should be of a 'de-minimus' quantity. In the very unlikely event that heavy contamination is encountered, as a alternate, disposal as a hazardous waste will be used as appropriate.
- Once all the equipment and piping is decontaminated the crew will commence disassembly more or less from the front of the system to the rear.
- All equipment that can be removed by hand, hand truck or forklift will be tackled first.
- Once all the equipment that can be removed in this manner is gone crane and custom heavy equipment contractors will be scheduled for the remainder of the equipment. As an alternative the deconstruction could be turned over to a qualified demolition contractor.
- Equipment and piping to be scrapped will go to the dumpsters and metal recycling bins as appropriate.
- Equipment to be sold or reused will be staged accordingly and appropriate used equipment vendors will be invited to bid on the equipment as appropriate.
- The process tent structure will be taken down by a contractor familiar with such operations. However, prior to taking it down various vendors who might be interested in purchasing this structure will be invited in to bid on it while it is still standing.
- Once all the treatment system equipment has been decontaminated and inspected to verify a clean debris surface closure of the treatment system will have been deemed complete.

3.2 Unit Inspection Prior to Decontamination

One of the recommendations in section 5.7 of the Guidance for Clean Closure is: "Waste removal and visual inspection must be completed before tank decontamination begins". We will have no problem with waste removal prior to decontamination. However, in order to enter these vessels while still contaminated will require self contained breathing apparatus (SCBA), permit required vessel entry (necessitating an outside contractor with retrieval device) thus representing a very onerous and time consuming task. The purpose of the internal inspection is to look for cracks and anything that might lead to a spill during decontamination. However, with the contamination still staining the walls cracks are not likely to be visible, the vessels are in secondary containment anyway, we regularly perform metal thickness checks to anticipate leaks and there just is not any good reason, therefore, to perform these inspections prior to decontamination. Additionally the vessels are externally inspected multiple times each shift. In the past, for vessels that have entered have first decontaminated and isolated it from the process such that a non-permit required vessel entry can be performed. Previously, in those rare cases where decontamination could not reasonably be performed, it has taken several weeks of prior preparation to meet all the requirements of a permit required vessel entry. Those requirements, include; a certified vessel emergency rescue supervisor (with documented yearly training), hazardous waste operations emergency response (HAZWOPER) trained crew (with documented yearly training), a certified rescue retrieval system, and full time atmospheric monitoring of the atmosphere in the vessel. There are very few contractors who possess these capabilities and lead times to schedule their services can be long. We strongly believe that the existing secondary containment, prior vessel wall thickness checks and shift by shift external vessel inspections **meet** the substantive requirements of section 5.7 regarding visual inspection prior to decontamination. Therefore, a variance is respectfully requested in order to avoid risky, time consuming and onerous internal inspections prior to decontamination. Additionally there are a number of vessels full of media (sand filters, carbon beds). We want these vessels operational with media during the decontamination operation and emptying them for inspection prior to decontamination precludes their operational use unless they were refilled with fresh media prior to the decontamination operation.

Complete vessel inspections after decontamination and prior to dismantling will be made. After decontamination, though, since the possibility of any hazardous atmosphere has been eliminated a non-permit required vessel entry can be performed. Any further spot cleaning required

3.3 Decontamination

That has been covered in section 3.1.

3.4 Identifying and Managing Contaminated Environmental Media

The extent of environmental media, soil and groundwater is under investigation through the Remedial Investigation and Feasibility Study (RI/FS) process required by the Agreed Order with Ecology. Ecology is presently reviewing RI/FS documentation and Interim Action Work Plans for cleanup or removal of contaminated environmental media at the site, including in the SER area.

3.5 Confirming Clean Closure

Confirming clean closure of the entire SER system applies to decontamination of metal tanks, tank systems, ancillary equipment, pumps and piping. Per Section 5.7 of the Guidance for Clean Closure.

Two options are allowed for decontaminating this sort of equipment:

- Meet the operating and performance standards associated with the Alternative Treatment Standards for Hazardous Debris appropriate to metal tanks and tank systems or,
- Propose a site specific decontamination method.

The Alternative Treatment Standards for Hazardous Debris (first option) includes high pressure steam and water sprays and steam boiling (physical extraction) as options for decontamination. The POR SER process has successfully employed these techniques since the beginning of the project for decontamination. Over the life of the project many tons of equipment and piping have been decontaminated and sent to metal recyclers or land filled after utilizing this method. All the crew has substantial prior experience utilizing this method and it has consistently achieved outstanding results (clean equipment and piping). Therefore high pressure steam and water spray and steam boiling are the chosen decontamination methods for the entire process.

3.6 Sampling and Analysis Plan and Constituents to be Analyzed

This section does not apply as the purpose of building the SER process was to perform fully contained clean-up of environmental media. The process has been operated release free for nearly eight years. It is expected that the system can be decontaminated without leading to the release of contamination. Therefore this section will not be addressed herein.

3.7 Closure Activity Manager

Karl Jolin is the qualified registered professional chemical engineer who constructed the working SER system as well as managed the operation the SER for eight years and has written or reviewed this plan will also be in charge of the closure activity.

3.8 Role of Independent Qualified Registered Professional Engineer

An independent qualified registered professional engineer, who has familiarity with SER operation, will be engaged to observe and verify the current status of the closure, to review records of the closure activities to date, to interview SER operations staff and other participants, and to field observe any remaining closure efforts.

3.9 Certification of Clean Closure

On completion of the closure activities, the POR will submit to Ecology a closure report certifying that the SER has been closed in accordance with the Closure Plan. The closure certification will be signed by POR management, and signed and stamped by the independent qualified registered professional engineer engaged under Section 3.8.

4.0 Conditions That Will Be Achieved When Closure is Complete

When closure is complete, Port staff will have completely removed the SER system. All waste and all unit parts, associated equipment and piping will be removed and properly prepared for sale or offsite disposal.

5.0 Closure Schedule

Closure is expected to take approximately six months from the start date on October, 24, 2011.

6.0 Closure Cost Estimate

A monthly expenditure of $250,000 includes, labor, material and outside contractors for the duration of closure. However, the duration of closure is in question given the challenges inherent with a custom one of a kind operation.

6.1 Financial Assurance for Closure

SER system was installed and operated and will be closed using funds provided by Ecology through Model Toxics Control Act grants and loans to the Port. A total of approximately $65 million has been granted and loaned to the Port. A grant and loan in the amount of $10 million was awarded to the Port for the 2012 – 2013 biennium from which SER closure will be conducted.

APPENDIX B

FORMER PWT SITE TERRESTRIAL ECOLOGICAL EVALUATIONS

APPENDIX B FORMER PWT SITE TERRESTRIAL ECOLOGICAL EVALUATIONS

CONTENTS

This appendix consists of the Upland Off-Property Terrestrial Ecological Evaluation (TEE) (Appendix B-1), the Supplemental TEE Evaluation for the Off-Property (Appendix B-2), and the LRIS Terrestrial Ecological Evaluation (Appendix B-3).

The Upland Off-Property TEE was first submitted to the Washington State Department of Ecology (Ecology) on January 23, 2012 and was included in the Draft RI/FS. In response to Ecology's comments, a Final Off-Property TEE was submitted on July 3, 2012, and was approved by Ecology on July 31, 2012.

The Final Off-Property TEE recommended additional sampling which was completed in September 20, 2012, with results presented in the January 15, 2013 Supplemental TEE Evaluation for the Off-Property. The Supplemental Evaluation presents additional dioxin data collected and, all previous dioxin data relevant to the TEE has been updated to ensure consistent treatment of interferences and non-detects during data qualification (see Appendix F). Updated dioxin and furan TEQs are calculated according to the methodology developed in coordination with Ecology; the methodology is described in the Final Off-Property TEE. Therefore, the Supplemental Evaluation contains the complete, updated dioxin dataset and the most recent evaluation of potential risk to ecological receptors in the off-property area. The Supplemental Evaluation was approved by Ecology on February 22, 2013.

The LRIS Terrestrial Ecological Evaluation was submitted to Ecology on April 13, 2010 and approved by Ecology on June 30, 2010. This TEE is presented exactly as it was submitted to Ecology with the exception of Table 1 "Soil Analytical Results" in which the dioxin toxicity equivalent (TEQ) data has been removed. Instead, the supplemental Table in Appendix B-3 presents the updated dioxin TEQ data and updated notes page, which fully explains all abbreviations and qualifiers in the tables. The dioxin data has been updated to ensure consistent treatment of interferences and non-detects during data qualification and calculation of TEQs. Updated TEQs are calculated according to the methodology developed in coordination with Ecology and are described in Appendix F.

As presented in the original Table 1, the TEQs in the supplemental Table are also compared to the Model Toxics Control Act (MTCA) Wildlife Ecological Indicator Concentration calculated by Malcolm Pirnie in 2007 (182 ng/kg). In all cases the original and updated TEQs either both exceed or both do not exceed the ecological screening criteria. Therefore, updating the dioxin TEQ calculation method does not change the interpretation of the dioxin data presented in the original report.

Vancouver, Washington 98661-462

Re: Final Terrestrial Ecological Evaluation for the Off-Property Former Pacific Wood Co. Treating Site Agreed Order No. 01TCPSR-3119

Dear Mr. Rankine:

On behalf of the Port of Ridgefield (Port), Maul Foster & Alongi, Inc. (MFA) has prepared this final terrestrial ecological evaluation (TEE) for the off-property area located adjacent to the Port's Lake River Industrial Site (LRIS) at 111 West Division Street in Ridgefield, Washington. Historical operations of Pacific Wood Treating Company (PWT) on the LRIS resulted in wood-treating chemical impacts to soil and groundwater. Remedial investigations and feasibility studies (RI/FSs) are being conducted to evaluate and manage site-related chemical impacts to soil and groundwater. The RI/FSs will be completed consistent with the requirements of the Model Toxics Control Act (MTCA) and the Agreed Order No. 01TCPSR-3119 between the Washington State Department of Ecology (Ecology) and the Port. TEEs for the LRIS property (MFA, 2010b) and for soil north of Cell 4 in the Ridgefield National Wildlife Refuge (MFA, 2010e) were submitted to and approved by Ecology (Ecology, 2010a,b). In a verbal communication to MFA on September 26, 2010, Ecology requested that a TEE be completed to evaluate surface soils for the off-property areas just to the east and south of the LRIS (see Figure 1). In response, MFA submitted an off-property TEE on January 23, 2012. In a subsequent series of communications, MFA and Ecology refined the approach to developing appropriate cleanup levels. This letter updates the previous TEE to reflect that approach.

In coordination with Ecology, the Port has conducted sampling of upland off-property areas adjacent to the LRIS (see Figure 1). Off-property sampling was conducted in July 2008; February 2009; June, August, and September, 2010; and May 2011. Wood-treating chemicals, including metals (arsenic, chromium, copper, and zinc), pentachlorophenol, and polycyclic aromatic hydrocarbons (PAHs), were analyzed in off-property soil samples along with dioxin (dibenzo-p-dioxin) and furan (dibenzofuran) compounds. In these off-property areas, no wood-treating chemicals have been detected above applicable cleanup levels. Results were previously submitted (MFA, 2010a,c,d; 2011).

This letter presents a site-specific TEE for the off-property area, following the procedures outlined in Washington Administrative Code (WAC) 173-340-7490 and WAC 173-340-7493. The purpose of this TEE is to present sufficient information to evaluate the surface soil data with respect to ecological screening values (see WAC 173-340-7490(1)(b)). This letter report for the off-property TEE presents:

- A summary of the off-property surface soil data
- An ecological exposure assessment for the off-property soil east and south of the LRIS
- Derivation of ecological indicator concentrations (EICs) for dioxins and furans in soil
- Ecological screening of chemicals analyzed in soil

PROBLEM FORMULATION

Exposure pathways and points and chemicals of ecological concern (CECs) are identified to define the focus of the TEE as follows:

Exposure Pathways: Currently, the off-property area just east of the LRIS includes the Port-owned Railroad Avenue property and residential properties. The properties south of the LRIS are marina properties and include the parking and landscaped areas for the Port-owned and privately owned McCuddy's marina properties. Figure 2 displays the zoning designations for the off-property areas. These areas do not provide important ecological habitat. While it is possible for wildlife to visit the off-property areas, potential exposures to impacted soil are expected to be minimal because there is substantial human disturbance and development and no important resources for wildlife. The exposure routes assessed for this off-property TEE include ingestion of soil and of dioxins in consumed plant material or prey.

Exposure Points: The exposure point evaluated for this off-property TEE includes the area east and south of the LRIS and is defined by the soil point of compliance of 0 to 15 feet below ground surface (bgs) as stated in WAC 173-340-7490 (4)(b). However, all samples collected in the off-property area are representative of surface soil (0 to 0.5 foot bgs) concentrations.

CECs: CECs are identified by comparing off-property soil concentrations to EICs. EICs are from WAC 173-340-900 Table 749-3, except for zinc and dioxins and furans (derivation of zinc and dioxin and furan EICs are described further below). Tables 1, 2, and 3 summarize concentrations in soil for metals, pentachlorophenol and PAHs, and dioxins and furans, respectively. For metals, off-property soil concentrations are also compared with default natural background soil metals concentrations for Clark County (Ecology, 1994). Only concentrations of zinc and dioxins and furans exceeded EICs. Exceedances are described further below:

> Zinc concentrations exceeded the EIC for plants of 160 milligrams per kilogram (mg/kg)[1] in one of 13 samples at sample location SS-37 (see Table 1).

---

[1] The EIC for zinc is based on a literature survey conducted by MFA consistent with MTCA requirements, submitted on May 30, 2012, and accepted by Ecology via electronic mail on June 15, 2012. See Attachment 1.

Zinc concentrations do not appear to result in adverse effects to plants. Plant life in the area appears abundant and unaffected by chemical impacts. Further, the off-site area complies with MTCA criteria identified in 173-340-740 as follows:

- The 95 percent upper confidence limit on the mean is 121, which is less than the EIC of 160 mg/kg (see Attachment 2 for statistics).
- No single sample concentration is greater than two times the soil cleanup level.
- No more than ten percent of the sample concentrations exceeds the soil cleanup level.

In addition, all sample concentrations are well below the soil biota and wildlife EICs. Therefore, zinc is not selected as a CEC.

- As shown in Table 2, pentachlorophenol and PAHs do not exceed screening levels for ecological receptors. Therefore, these constituents are not selected as CECs for the off-property.
- For dioxins, Table 749-3 presents indicator concentrations only for wildlife and not for plants or soil biota; therefore, this off-property TEE assessed only exposures of wildlife to dioxins in off-property soils. The Table 749-3 EIC for total dioxins and total furans is 2 nanograms per kilogram (ng/kg). This EIC has remained unchanged since at least 2003, and does not reflect recent updates in how Ecology evaluates the toxicity of dioxin and dioxin-like compounds (Ecology, 2007a,b; U.S. Environmental Protection Agency [USEPA], 2008; Van den Berg et al., 2006). In addition, the Table 749-3 EIC is also below Ecology's estimated natural background concentrations for Washington soils. Furthermore, Ecology recognizes that MTCA does not appear to be specific on methodology for dioxins and furans in terms of ecological risk and that an updated method for calculation of dioxin and furan EICs is needed. Ecology and MFA developed a method for developing dioxin and furan EICs appropriate for the PWT site; the method for developing EICs and evaluating dioxin and furan risk to ecological receptors is discussed below.

Ecological Indicator Concentrations for Dioxins and Furans

Ecology is in the process of formulating methodology as part of the forthcoming Terrestrial Ecological Evaluation Technical Assistance document. The process for developing EICs for dioxins and furans for ecological risk assessment is different from the approach used for calculating cleanup levels for human health risk assessment. Ecological risk assessment treats dioxins as one chemical mixture and furans as another, whereas human health risk assessment (in MTCA) treats dioxins and furans as one combined chemical mixture.

For ecological risk assessment, the sum of the toxic equivalency factor (TEF) for the seven dioxin congeners (commonly referred to as the toxicity equivalency quotient, i.e., TEQ) is compared to the calculated EIC for the dioxin sentinel congener. Similarly, the TEQ for the ten furan congeners is compared to the calculated EIC of the furan sentinel congener. The sentinel congener for each group is the congener with the highest TEF (equal to 1) against which the relative toxicity of other congeners within each group is measured. For dioxins, both 1,2,3,7,8-pentochloro dibenzo-p-dioxin and 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) have mammal-based TEF values equal to 1. For furans, both 2,3,7,8-tetrachlorodibenzofuran (2,3,7,8-TCDF) and 2,3,4,7,8-pentachloro dibenzofuran have avian-based TEF values equal to 1. However, use of 2,3,7,8-TCDD in calculations is preferable, given that it has been best studied and has associated toxicity and bioaccumulation values readily available in literature. For the same reason, use of 2,3,7,8-TCDF in calculating furan-associated risk is most reliable. A description of the derivation of dioxin and furan EICs follows.

Table 749-4 (Attachment 3) presents the MTCA wildlife exposure model to be used for site-specific evaluations, with default dioxin- and furan-specific parameters noted in Table 749-5 (see Attachment 4). The following equations are applied to evaluate risk to three receptors (shrew [*Sorex*], robin [*Turdus migratorius*], and vole [*Microtus*]) that act as surrogate receptors for mammalian predators, avian predators, and mammalian herbivores, respectively:

(1) Mammalian predator:

$$SC_{MP} = (T_{Shrew})/[(FIR_{Shrew,DW} \text{ x } P_{SB(Shrew)} \text{ x } BAF_{Worm}) + (SIR_{Shrew,DW} \text{ x } RGAF_{Soil,Shrew})]$$

(2) Avian predator:

$$SC_{AP} = (T_{Robin})/[(FIR_{Robin,DW} \text{ x } P_{SB(Robin)} \text{ x } BAF_{Worm}) + (SIR_{Robin,DW} \text{ x } RGAF_{Soil,Robin})]$$

(3) Mammalian herbivore:

$$SC_{MH} = (T_{Vole})/[(FIR_{Vole,DW} \text{ x } P_{Plant,Vole} \text{ x } K_{Plant}) + (SIR_{Vole,DW} \text{ x } RGAF_{Soil,Vole})]$$

Briefly, SC represents soil concentrations protective of wildlife (EICs), T represents toxicity reference values (or TRVs), FIR represents food ingestion rate, P is proportion of contaminated food in diet, BAF is the earthworm bioaccumulation factor, SIR is soil ingestion rate, RGAF is the gut adsorption factor for a hazardous substance in soil expressed relative to the gut adsorption factor for the hazardous substance in food, and K_{Plant} is the plant uptake coefficient. Units and default values are presented in Table 749-4 (Attachment 3). As specified in Table 749-4, the lowest of the three SC values calculated is to be used as the EIC for a site-specific evaluation.

MTCA (WAC 173-340, Sections 7490 to 7494) uses K_{Plant} and soil to earthworm BAFs in the wildlife exposure model to estimate the concentration of a hazardous substance expected to be present in biota, given a measured concentration in the soil. The site-specific wildlife exposure model presented here varies K_{Plant} and BAFs to calculate EICs (SC); all other parameters are MTCA defaults.

Plant Uptake Coefficients: In general, chemicals that migrate from subsurface soil into aboveground plant structures (e.g., leaves) first dissolve from soil into soil pore water, and are then taken up by roots (McKone and Maddalena, 2007). They can be transported from roots to leaves in the dissolved phase through either transpiration or translocation. Plant uptake of chemicals from soil is determined by numerous factors such as the species of plant, soil type, pH in soil, organic carbon content of soil, temperature, and nutrient levels. Organic compounds with high molecular weights (e.g., dioxins) are relatively insoluble and plant uptake of these chemicals is low (McKone and Maddalena, 2007; Travis and Arms, 1988).

K_{Plant} for aboveground plant parts is typically defined as the ratio of the chemical concentration in the plant over the concentration in soil (expressed as dry weight). Travis and Arms (1988) found that a K_{Plant} was associated with the logarithm of the octanol-water partition coefficient (log K_{ow}) for a chemical. The K_{ow} is a measure of chemical solubility. The following equation can therefore be used to estimate a conservative K_{Plant} for organic chemicals (Travis and Arms, 1988):

$$\mathrm{Log}K_{Plant} = 1.588 - 0.578\log K_{ow}$$

MTCA uses the equation based on Travis and Arms (1988) to model uptake of organic chemicals into plants (Table 749-5; see Attachment 4), and this equation was applied for 2,3,7,8-TCDD to determine mammalian herbivore EICs for dioxins. Mammalian herbivore EICs were not calculated for furans, and a furan mammalian herbivore TRV currently is not provided in MTCA (Attachment 4). Log K_{ow} values were sourced from the USEPA (2003); the minimum values reported were used in equations, as these result in the most protective EICs (see Table 4).

Soil to Earthworm Bioaccumulation Factors: Soil to earthworm BAFs are typically defined as the ratio of the chemical concentration in the earthworm over the concentration in soil (expressed as dry weight). MTCA uses a soil to earthworm BAF value of 48 (dry weight basis) for both dioxin and furan congeners; the basis and source of this value are not identified in Table 749-5 (Attachment 4). The USEPA (1999) presented a recommended 2,3,7,8-TCDD soil to soil invertebrate BAF of 1.59 (wet weight basis). Soil to soil invertebrate BAFs expressed on a wet weight tissue concentration basis can be converted to a dry weight tissue concentration basis, using an assumed water content of 84 percent for earthworms (USEPA, 1993). Converted to a dry weight basis, the recommended 2,3,7,8-TCDD BAF is 9.94.

The recommended 2,3,7,8-TCDD BAF is within the range of BAFs presented in other studies. Sample et al. (1998) evaluated literature-derived soil to earthworm BAFs for 2,3,7,8-TCDD and presented a mean BAF of 11.7 (dry-weight basis) and a 90th percentile BAF of

22.2 (dry-weight basis). At the Rayonier site in western Washington, colocated soil and earthworm samples were analyzed to determine a BAF of 0.361 (dry weight basis) for 2,3,7,8-TCDD, showing relatively low bioaccumulation potential (Malcolm Pirnie, 2007).

To ensure consistency with derivation of the 2,3,7,8-TCDD BAF, the 2,3,7,8-TCDF BAF was calculated based on the USEPA (1999) reported value (1.27 as measured on a wet weight basis). The resulting recommended 2,3,7,8-TCDF BAF is 7.94 (dry weight tissue basis).

TRVs: 2,3,7,8-TCDD TRVs are provided in MTCA for both mammalian and avian receptors, and dioxin EICs were calculated for all receptor surrogates. For 2,3,7,8-TCDF, only an avian receptor TRV is provided. Thus the furan EIC was calculated only for the avian surrogate. The furan EIC is expected to be protective of other receptor types, given that furan toxicity is known to impact birds most significantly (USEPA, 2008).

For a summary of all calculated EICs see Table 4. Multiple MTCA default parameters (e.g. ingestion proportions/rates and TRVs) used in calculations are protective of the conservative end of the species exposure distribution. For example, the proportion of contaminated food for mammalian herbivore receptors is assumed to be 100% and all TRVs are based on lowest observable effects levels. Given multiple layers of conservatism inherent to the EIC model, calculated EICs may therefore be overly conservative. In addition, the following selected EICs are the lowest and therefore the most protective of all calculated EICs. The selected 2,3,7,8-TCDD EIC is 9.8 ng/kg for dioxins (based on the shrew surrogate receptor for mammalian predators) and the selected 2,3,7,8-TCDF EIC is 11.4 ng/kg (based on the robin surrogate receptor for avian predators).

Dioxin and Furan Screening

For the purposes of this screening evaluation, all soil data collected throughout the off-property area for dioxins and furans were included. The sum of the TEF applied to the seven dioxin congeners (dioxin TEQ) is compared to the calculated EIC. Similarly, the furan TEQ for the ten furan congeners was calculated and compared to the calculated EIC. To be consistent with the receptor of question, mammalian TEFs were applied for dioxin screening, whereas avian TEFs were applied for the furan screening (Van den Berg et al., 2006).

Table 5 presents the results of the ecological screening evaluation. Data were screened only against the most protective EIC for dioxin and furan TEQs, respectively. The screening was completed only on a point-by-point basis (WAC 173-340-740). Thirteen locations exceeded the dioxin TEQ EIC, while 12 exceeded the furan TEQ EIC (see Table 5 and Figure 3). Thus, based on this preliminary screening, dioxins are identified as CECs for off-property soils.

Assessing risk to receptors based on surface soil results alone (i.e., not including subsurface) is likely to be unrepresentative of the actual exposure to ecological receptors. Burrowing mammals, for example, are exposed to subsurface soils in addition to surface soils, and birds feed on organisms that inhabit subsurface as well as surface soils. Given that the dioxins and furans are thought to be atmospherically deposited and that these chemicals are relatively immobile in soils, surface soil is likely to have the highest concentrations. If subsurface exposure is taken into account, then the exposure to ecological receptors is likely to be significantly reduced.

In summary, metals, pentachlorophenol, and PAHs are not identified as CECs for off-property soils. Dioxins and furans in surface soil exceed screening levels at certain locations in off-property surface soils; however, actual exposure to ecological receptors is anticipated to be less than concentrations representative of surface soil. If you have any questions, please contact us.

Sincerely,

Maul Foster & Alongi, Inc.

LIMITATIONS

The services undertaken in completing this report were performed consistent with generally accepted professional consulting principles and practices. No other warranty, express or implied, is made. These services were performed consistent with our agreement with our client. This report is solely for the use and information of our client unless otherwise noted. Any reliance on this report by a third party is at such party's sole risk.

Opinions and recommendations contained in this report apply to conditions existing when services were performed and are intended only for the client, purposes, locations, time frames, and project parameters indicated. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations subsequent to performance of services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this report.

NOTES:

Clark County Background from Washington State Department of Ecology October 1994 Natural Background Soil Metals Concentrations in Washington State.

TEE values from WAC 173-340-900 Table 749-3.

ft. bgs = feet below ground surface.

mg/kg = milligrams per kilogram.

TEE = terrestrial ecological evaluation.

[a] Zinc TEE value based on USEPA Eco-SSL value. See text for further details.

Table 2
Pentachlorophenol and Polycyclic Aromatic Hydrocarbons in Surface Soil (µg/kg)
Off-Property Lake River Industrial Site

NOTES:

E = estimated concentration.

ft. bgs = feet below ground surface.

HpCDD = heptachloro dibenzo-p-dioxin.

HpCDF = heptachloro dibenzofuran.

HxCDD = hexachloro dibenzo-p-dioxin.

HxCDF = hexachloro dibenzofuran.

J = estimated concentration.

MRL = method reporting limit.

ng/kg = nanogram per kilogram (parts per trillion).

OCDD = octachloro dibenzo-p-dioxin.

PeCDF = pentachloro dibenzofuran.

TCDD = tetrachloro dibenzo-p-dioxin.

TCDF = tetrachloro dibenzofuran.

U = not detected at or above MRL.

UJ = because of matrix interference, analyte could not be quantified; concentration is no greater than elevated MRL presented on table.

Vancouver, Washington 98661-462

Re: Proposal for a Zinc Soil EIC for Plants based on a Literature Survey, Former Pacific Wood Co. Treating Site, Agreed Order No. 01TCPSR-3119

Dear Mr. Rankine:

On behalf of the Port of Ridgefield, Maul Foster & Alongi (MFA) has prepared this letter to propose a zinc soil ecological indicator concentration (EIC) based on a literature survey. MFA understands that levels of zinc in the upland off-property area exceed the plant EIC of 86 mg/kg in Table 749-3 of the Model Toxics Control Act (MTCA). Upland off-property soil concentrations are well below wildlife and soil biota MTCA EICs of 360 mg/kg and 200 mg/kg, respectively. Soil concentrations only exceed the EIC listed for plants of 86 mg/kg. The listed EIC is footnoted in MTCA with "Benchmark replaced by Washington state natural background concentration". Therefore, it appears that the EIC for protection of plants is based on background levels rather than on anticipated adverse effects on plants.

A literature survey was conducted in accordance with WAC 173-340-7493(4) to determine an alternative EIC that is protective of plants based on anticipated adverse effects. As stated in WAC 173-340-7493, a literature survey may be used for purposes including identifying a soil concentration for the protection of plants relevant to site-specific conditions. The use of the US Environmental Protection Agency (USEPA) ecological soil screening level (Eco-SSL) for zinc of 160 mg/kg is proposed. WAC 173-340-7493(4) requirements are provided below in italics; justification for the appropriateness of the alternative zinc EIC of 160 mg/kg is provided below each relevant section.

(4) Literature surveys.

(a) Toxicity reference values or soil concentrations established from the literature shall represent the lowest relevant LOAEL found in the literature. Bioaccumulation factor values shall represent a reasonable maximum value from relevant information found in the literature.

USEPA identified 680 papers from the literature search process for further review. Of these papers acquired, 78 met acceptance criteria and 5 were classified eligible for Eco-SSL derivation. The Eco-SSL is calculated as the geometric mean of the maximum acceptable toxicant concentration (MATC) values. MATC values are calculated as the geometric mean of both NOAEL (no observed adverse effects level) and LOAEL (lowest observed adverse effects level) values. Thus MATC values are more conservative (i.e., protective) than the LOAEL values MTCA specifies for use (see section (a) above) and Eco-SSLs are therefore protective of the conservative end of the exposure and effects species distribution.

(i) Literature benchmark values should be obtained from studies that have test conditions as similar as possible to site conditions.

The Eco-SSL is calculated as the geometric mean of MATC values for three plant species (representative of several widely distributed and utilized species) under varying test conditions (pH and percent organic matter); pH ranged from 4.3-6.5 and organic matter from 0.8 percent to 2.6 percent. Given studies with varying species and test conditions were incorporated, site conditions similar to those found at the upland off-property area are likely accounted for.

(ii) The literature benchmark values or toxicity reference values should correspond to the exposure route being assessed.

Eco-SSLs for plants correspond to the exposure route being assessed, i.e., root uptake of zinc from soil.

(iii) The toxicity reference value or bioaccumulation factor value shall be as appropriate as possible for the receptor being assessed. The toxicity reference value should be based on a significant endpoint, as described in subsection (2) of this section.

Plant toxicity concentrations for oats (*Avena sp.*) were predominantly used in development of zinc Eco-SSLs (and to a lesser extent soybean [Glycine max] and lettuce [Lactuca sativa]). Oats are part of the true grass family (*Poaceae*) and therefore likely approximate the physiology and therefore susceptibility to zinc found in the ruderal grasses and plants common to the off-property upland.

(iv) The literature benchmark value or toxicity reference value should preferably be based on chronic exposure.

Studies selected for Eco-SSL derivation evaluated impacts of chronic zinc exposure on plant growth.

(v) The literature benchmark value, toxicity reference value, or bioaccumulation factor should preferably correspond to the chemical form being assessed. Exceptions may apply for toxicity reference values

where documented biological transformations occur following uptake of the chemical or where chemical transformations are known to occur in the environment under conditions appropriate to the site.

The Eco-SSL discussed corresponds to the chemical form being assessed (zinc).

(b) A list of relevant journals and other literature consulted in the survey shall be provided to the department. A table summarizing information from all relevant studies shall be provided to the department in a report, and the studies used to select a proposed value shall be identified. Copies of literature cited in the table that are not in the possession of the department shall be provided with the report. The department may identify relevant articles, books or other documents that shall be included in the survey.

Please see http://www.epa.gov/ecotox/ecossl/pdf/eco-ssl_zinc.pdf for the USEPA document detailing studies evaluated and studies included in Eco-SSL calculations (Table 3-1).

Summary

Based on a literature survey in accordance with MTCA requirements, the Eco-SSL for zinc of 160 mg/kg is protective of the conservative end of the exposure and effects species distribution. The majority of the upland off-property soil samples are less than 160 mg/kg, with only one sample exceedance at 161 mg/kg. The offsite area complies with MTCA criteria using the tests identified in 1713-340-740, i.e., the 95 percent upper confidence limit on the mean is less than the soil cleanup level, no single sample concentration is greater than two times the soil cleanup level, and less than ten percent of the sample concentrations exceed the soil cleanup level. Please also note that vegetation in the vicinity of elevated zinc concentrations is abundant (i.e., shows no signs of toxic effects).

Sincerely,

Maul Foster & Alongi, Inc.

Re: Supplemental Terrestrial Ecological Evaluation for the Off-Property
Former Pacific Wood Treating Corporation Site
Agreed Order No. 01TCPRSR-3119

Dear Mr. Rankine:

On behalf of the Port of Ridgefield (Port), Maul Foster & Alongi, Inc. (MFA) has prepared this terrestrial ecological evaluation (TEE) of the off-property areas located adjacent to the Port's Lake River Industrial Site (LRIS) at 111 West Division Street in Ridgefield, Washington, formerly operated by Pacific Wood Treating Corporation. A final off-property TEE, indicating potential unacceptable ecological risk resulting from exposure to polychlorinated dibenzo dioxins (dioxins) and polychlorinated dibenzo furans (furans) in surface soil in the off-property areas, was submitted by MFA (MFA, 2012a) and approved by the Washington State Department of Ecology (Ecology) on July 31, 2012 (Ecology, 2012a). Additional sampling was proposed to refine the ecological exposure to dioxins and furans in soil. A supplemental sampling and analysis plan (SAP) was submitted to Ecology in August 2012 (MFA, 2012b) and was approved by Ecology on August 22, 2012 (Ecology, 2012b). The results of the additional sampling and an assessment of risk to ecological receptors resulting from potential exposure to dioxins and furans are provided below.

BACKGROUND

In coordination with Ecology, the Port has conducted several soil sampling events in upland off-property areas adjacent to the LRIS. Off-property areas and sampling locations are shown on Figure 1. As shown on Figure 1, the off-property includes areas owned by the Port (Railroad Avenue and Marina properties), and other areas (Ridgefield National Wildlife Refuge property, the residential area, and the privately-owned McCuddy's marina). Off-property sampling was previously conducted in July 2008; February 2009; June, August, and September, 2010; and May 2011. Wood-treating chemicals, including metals (arsenic, chromium, copper, and zinc), pentachlorophenol, and polycyclic aromatic hydrocarbons, along with dioxins and furans, were analyzed in off-property soil samples. The final TEE (MFA, 2012a) shows that chemicals in the off-property areas are not expected to result in unacceptable risk to ecological receptors, with the possible exception of dioxins and furans. Dioxin and furan ecological indicator concentrations (EICs) protective of avian receptors that may feed on worms that have the potential to accumulate organics present in the soil were established in the final TEE. Dioxin and furan toxicity equivalent quotients (TEQs) in multiple samples exceeded these levels. Ecology approved the TEE on July 31, 2012 (Ecology, 2012a).

Historical soil samples were collected from the surface (top 0.5 foot) of soil. However, assessing risk to ecological receptors based on surface soil results alone (i.e., not including subsurface) is likely to be unrepresentative. Assuming that dioxin and furan concentrations decrease with depth, actual receptor exposure is expected to be less than surface soil concentrations indicate. Vertical composite sampling (specifically, homogenizing a core sample then analyzing the result) is appropriate when the goal is to obtain the mean concentration over a depth of interest in which receptor exposure can occur (Ecology 1995). Therefore, vertical composited samples of surface and subsurface soil were collected, consistent with the Ecology-approved SAP (MFA, 2012b) and a Ecology memorandum regarding the use of composite samples for ecological risk assessment (Ecology 2012c), to refine the ecological exposure assessment.

2012 OFF-PROPERTY COMPOSITE SOIL SAMPLING

The objective of the supplemental soil sampling was to estimate the ecological exposure of worms that are the main food source for birds to dioxins and furans in off-property soil. Vertical soil samples integrating surface and subsurface soil layers were collected with a continuous coring device on September 20, 2012, at eight off-property locations. The composite soil sample locations were selected based on whether historical surface soil concentrations exceeded dioxin and/or furan EICs. However, as specified in the SAP, additional sample collection was specifically excluded in Port-owned properties:

- The Railroad Avenue Property (see Figure 1) is undeveloped at this time, but because the Port anticipates developing commercial parking lots on these parcels, future ecological exposure to soil in this area is expected to be minimal.
- Ecological exposure at the Port-Owned Marina Property south of the LRIS is limited. This area includes primarily paved parking and landscaped areas for the Port-owned boat launch; the Port plans to retain ownership and continue to use the area for parking and/or to develop this waterfront for mixed use in the foreseeable future. The soil around historical sample, SS-6, collected between the LRIS property boundary and the paved area of the Marina property (see Figure 1) has been capped with approximately 1 foot of clean soil and a polypropylene geotextile fabric has been placed above the native, impacted soil and below the clean layer. This fabric acts as a barrier to potential ecological exposure. Because ecological receptors are not exposed to soil surrounding sample SS-6, the sample results are not further evaluated in terms of ecological risk.

The samples were integrated over the biologically active soil zone of 0 to 6 feet below ground surface (bgs) (Washington Administrative Code [WAC] 173-340-7490(4)(a)) in accordance with the SAP. This sampling depth provides data that are representative of the depths where exposure to persistent organic compounds such as dioxins and furans may occur, and composite sampling is appropriate for understanding risk to invertebrates inhabiting the soil column (Ecology, 2012c) and their potential predators. Specifically, three main ecological types of earthworms (which higher trophic level predatory receptors such as birds may feed on) are found in the Columbia River Basin: epigeic, endogeic, and anecic (USDA, 2000). Epigeic worms are generally found on the surface and in shallow subsurface in areas of substantial leaf litter. Endogeic worm are generally found at depths of up to 20 cm below the surface. Anecic worms are the largest worms and construct vertical burrows that can reach up to 6 feet deep (e.g., Gupta et al., 2009). All of these worm types are potentially present in the off-property area (soil moisture, pH, and soil temperature is likely adequate to support all worm type; e.g. [USDA 2000]) and are found at the surface or come to surface to acquire organic matter, leaving them exposed to predators. In the off-property area, the soil cores collected verify that adequate soil (i.e., damp silt/fine sand/clay soils which retains organic matter [see boring logs provided as an Attachment]) at depths up to 10 feet is generally present. Therefore, worms in the off-property area potentially acquire organic matter from soils at depths up to approximately 6 feet, and any soil contamination acquired at the off-property area has the potential to transfer in the food chain because all worm types can be present at shallow subsurface and surface.

A continuous soil sample spanning only the top 4 feet of soil was collected at location SS-51 because woody debris at 4 feet bgs prevented collection of soil below this depth. Significant woody debris was also observed at SS-50 from approximately 6 to 10 feet bgs. Figure 1 shows the eight locations sampled, including six locations in the residential area and two locations in McCuddy's Marina (SS-50 and SS-51).

Composite samples were collected and described following procedures outlined in the SAP; soils from the sample interval (0-6 feet bgs) were thoroughly mixed (i.e., homogenized) and then subsampled to prevent an unbiased mean (Ecology, 2012c). All composite samples were analyzed for dioxins/furans by U.S. Environmental Protection Agency Method 1613B at Pace Analytical, Inc. (an Ecology-approved laboratory) under appropriate laboratory quality assurance/quality control procedures. The rest of the samples (i.e., archived samples collected from each 1-foot interval) were archived at the laboratory.

The laboratory analytical report is included as Attachment 1. A data quality assurance/quality control review of the analytical data was conducted; the review indicated that the data are acceptable for their intended use with the assigned data qualifiers. The data quality assurance/quality control review memorandum is provided as Attachment 2. The analytical sensitivity was adequate to compare with EICs.

SOIL COMPOSITE RESULTS

Dioxin and furan TEQs were calculated using the methods developed in coordination with Ecology and described by MFA (2012a). Qualified data were handled as follows:

- Congeners qualified as non-detect and flagged with a "U" are used in the TEQ calculations at one-half the associated value.
- Congeners qualified as estimated and flagged with a "J" are used without modification in the TEQ calculations.

Composite results for each location are provided in Table 1, and were compared to applicable EICs (dioxin TEQ EIC = 9.8 nanograms per kilogram [ng/kg]; furan TEQ EIC = 11.4 ng/kg) (MFA, 2012a) to evaluate the potential for ecological risk in the off-property areas (see Table 2). Dioxin TEQs ranged from 0.3 ng/kg to 14.4 ng/kg. Two samples, SS-47-Comp-0-6 (14.4 ng/kg) and SS-50-Comp-0-6 (11.2 ng/kg), exceeded the EIC, while the other six samples were at or well below the EIC. Only one sample (SS-47-Comp-0-6 at 12.8 ng/kg furan TEQ) exceeded the furan TEQ of 11.4 ng/kg. Figure 2 shows EIC exceedances for all locations based on samples previously collected (in locations where composite samples were not collected) and composite samples.

ECOLOGICAL RISK EVALUATION

To evaluate risk to ecological receptors resulting from off-property soils, a 95th upper confidence limit (UCL) was calculated for both the dioxin and furan TEQs. Calculations included all composite soil results reported here and previous surface sample results (MFA, 2012a) at stations where composite samples were not collected. Table 2 shows all samples used in the UCL calculation. TEQs were recalculated for historical data, as an updated approach to qualifying dioxin data has been coordinated with Ecology since the final TEE submission.

Note that this UCL evaluation is conservative, as surface samples (in addition to composite samples) are included in calculations. Surface samples are likely elevated relative to the subsurface, and actual exposure to receptors is anticipated to be less than surface soil concentrations indicate. This is further supported by the composite soil results that are consistently substantially lower than collocated surface sample results (see Table 2 for results of composite samples and previously collected collocated surface samples). As a result, the analyses conducted are likely to overestimate ecological risk.

Off-Property Ecological Risk

When including all off-property locations, the dioxin TEQ UCL (13.9 ng/kg and 22.1 ng/kg assuming gamma and lognormal distribution, respectively) exceeds the dioxin EIC of 9.8 ng/kg, while the furan TEQ UCL (10.5 ng/kg and 17.1 ng/kg assuming gamma and lognormal distribution, respectively) is below or above the furan EIC of 11.4 ng/kg, depending on the statistics applied. Therefore, unacceptable risk to ecological receptors may result from exposure to dioxins. The ProUCL output is provided as Attachment 3; gamma and lognormal distribution results are provided because data follow both gamma and lognormal distributions.

The highest dioxin TEQ concentrations in the off-property areas are generally in the Port-owned properties (see Table 2). The soil at sample location SS-6 has been remediated (see above) and additional analysis was conducted to evaluate whether remediation of the remaining Port-owned soils (i.e., the area including SS-37, SS-38, SS-39, SS-41, and SS-42) would mitigate for potentially unacceptable risk resulting from dioxins. A UCL was therefore calculated excluding Port-owned property samples; the ProUCL output is provided in Attachment 4.

Both the dioxin TEQ UCL (5.3 ng/kg and 7.9 ng/kg assuming gamma and lognormal distribution, respectively) and the furan TEQ UCL (3.6 ng/kg and 5.0 ng/kg assuming gamma and lognormal distribution, respectively) are well below the dioxin and furan EICs of 9.8 ng/kg and 11.4 ng/kg, respectively, for the off-property areas when excluding the Port-owned Properties. Other Model Toxics Control Act criteria for unrestricted land use (WAC 713-340-740) are also met, i.e., less than ten percent of the sample concentrations exceed the soil cleanup level (EIC), and no single sample concentration is greater than two times the soil cleanup level (EIC).

UNCERTAINTY ANALYSIS

Sampling methodology may, in some cases, contribute to uncertainty associated with exposure estimates. In the case of this TEE, vertical composite sampling was selected to limit the bias associated with estimating exposure using discrete samples. As discussed above, bioaccumulation of dioxins and furans in worms and subsequent ingestion by avian receptors is the exposure scenario for which the soil EICs were generated. Analyzing a composite of the top six feet of soil results in the most representative exposure concentration in any one location.

CONCLUSIONS

The analysis indicates that Port Railroad Avenue Property soils may result in unacceptable risk to ecological receptors, due to elevated dioxin TEQ. If this area is remediated (e.g., capped), no significant ecological risk is expected to result from concentrations of dioxins and furans remaining in off-property soils.

DISCUSSION

This report presents the results from the analyses performed on eight samples submitted by a representative of Maul Foster & Alongi. The samples were analyzed for the presence or absence of polychlorodibenzo-p-dioxins (PCDDs) and polychlorodibenzofurans (PCDFs) using USEPA Method 1613B. The reporting limits were based on signal-to-noise measurements. Method blank and field sample results with reporting limits corresponding to the lowest calibration points and adjusted for sample amount were included in Appendix A.

The recoveries of the isotopically-labeled PCDD/PCDF internal standards in the sample extracts ranged from 19-96%. Except for two low values, which were flagged "R" on the results tables, the labeled standard recoveries obtained for this project were within the target ranges specified in Method 1613B. Also, since the quantification of the native 2,3,7,8-substituted congeners was based on isotope dilution, the data were automatically corrected for variation in recovery and accurate values were obtained.

In some cases, interfering substances impacted the determinations of PCDD or PCDF congeners. The affected values were flagged "I" where incorrect isotope ratios were obtained or "P" where polychlorinated diphenyl ethers were present.

A laboratory method blank was prepared and analyzed with each sample batch as part of our routine quality control procedures. The results show the blanks to contain trace levels of selected congeners. These levels were below the calibration range of the method. Sample levels similar to the corresponding blank levels were flagged "B" on the results tables and may be, at least partially, attributed to the background. It should be noted that levels less than ten times the background are not generally considered to be statistically different from the background.

Laboratory spike samples were also prepared with the sample batches using clean sand that had been fortified with native standard materials. The results show that the spiked native compounds were recovered at 83-125%, indicating a high degree of accuracy for these determinations. Matrix spikes were prepared with the sample batches using sample materials from separate projects; results from these analyses will be provided upon request.

Results reported on a dry weight basis and are valid to no more than 2 significant figures.

Reporting Flags

A = Reporting Limit based on signal to noise

B = Less than 10x higher than method blank level

C = Result obtained from confirmation analysis

D = Result obtained from analysis of diluted sample

E = Exceeds calibration range

I = Interference present

J = Estimated value

Nn = Value obtained from additional analysis

P = PCDE Interference

R = Recovery outside target range

S = Peak saturated

U = Analyte not detected

V = Result verified by confirmation analysis

X = %D Exceeds limits

Y = Calculated using average of daily RFs

* = See Discussion

DATA VALIDATION MEMORANDUM

DATA QUALITY ASSURANCE/QUALITY CONTROL REVIEW

PROJECT NO. 9003.01.39 | OCTOBER 25, 2012 | PORT OF RIDGEFIELD

This report provides the results of the data quality assurance/quality control review of analytical results for soil samples collected by the Maul Foster & Alongi, Inc. project team at the off-property area at the former Pacific Wood Treating site. The samples were collected in September 2012.

Pace Analytical Services, Inc. (Pace) in Minneapolis, Minnesota, performed the analyses. Pace report number 10206267_1613B was reviewed. Polychlorinated dibenzo dioxins and polychlorinated dibenzo furans were analyzed by U.S. Environmental Protection Agency (USEPA) Method 1613B.

DATA QUALIFICATIONS

Analytical results were evaluated according to applicable sections of USEPA procedures (USEPA, 2005) and appropriate laboratory and method-specific guidelines (MFA, 2012; Pace, 2012; USEPA, 1986).

Results reported as an estimated maximum potential concentration (EMPC) were qualified with a "U" qualifier.

Method blank detections associated with total tetrachlorodibenzofuran (TCDF) also resulted in "U" qualification of select samples. Details are provided in the Blanks section of this document.

The data are considered acceptable for their intended use, with the appropriate data qualifiers assigned.

HOLDING TIMES, PRESERVATION, AND SAMPLE STORAGE

Holding Times

Extractions and analyses were performed within the recommended holding time criteria.

Preservation and Sample Storage

The samples were preserved and stored appropriately.

BLANKS

Method Blanks

Laboratory method blank analyses were performed at the required frequencies. For purposes of data qualification, the method blanks were associated with all samples prepared in the same analytical batch. Multiple method blank results had blank detections between the estimated detection limit (EDL) and the reporting limit for various compounds. No actions were taken when the sample result was greater than five times the blank result. Sample results that were not greater than five times the method blank detections resulted in the following qualifications:

Sample	Analyte	Original Results (ng/kg)	Qualified Result (ng/kg)
SS-48-Comp-0-6	Total TCDF	0.22	0.22 U
SS-44-Comp-0-6	Total TCDF	0.13 U	0.13 UJ

ng/kg = nanograms per kilogram.
UJ = The analyte was not detected at a level greater than or equal to the adjusted CRQL and the reported adjusted CRQL is approximate.

All other method blank results met acceptance criteria.

Trip Blanks

Trip blanks were not required for this sampling event.

Equipment Rinsate Blanks

Equipment rinsate blanks were not required for this sampling event, as all samples were collected using dedicated, single-use equipment.

SURROGATE/INTERNAL STANDARD RECOVERY RESULTS

The samples were spiked with internal standard compounds to evaluate laboratory performance on individual samples.

The reviewer took no action based on minor internal standard acceptance criteria exceedances for percent recovery, as the affected compounds were previously qualified as "U" based on EMPC results.

The laboratory appropriately documented and qualified internal standard outliers. Associated batch quality assurance/quality control for samples with internal standard outliers was within acceptance limits. All remaining internal standard recoveries were within acceptance limits.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE RESULTS

MS/MSD results are used to evaluate laboratory precision and accuracy. No MS/MSD analyses were performed for these results, as they are not required by USEPA Method 1613B.

LABORATORY DUPLICATE RESULTS

Duplicate results are used to evaluate laboratory precision. No duplicate analyses were performed for these results, as they are not required by USEPA Method 1613B.

LABORATORY CONTROL SAMPLE/LABORATORY CONTROL SAMPLE DUPLICATE RESULTS

An LCS/LCSD is spiked with target analytes to provide information on laboratory precision and accuracy. The LCS/LCSD samples were extracted and analyzed at the required frequency. All LCS/LCSD analytes were within acceptance limits for percent recovery.

REPORTING LIMITS

Pace used both routine reporting limits and EDLs for non-detect results, except for samples requiring dilutions because of high analyte concentrations and/or matrix interferences. Sample results are being reported using the EDLs provided with proper data qualifications assigned.

DATA PACKAGE

The data packages were reviewed for transcription errors, omissions, and anomalies. None were found.

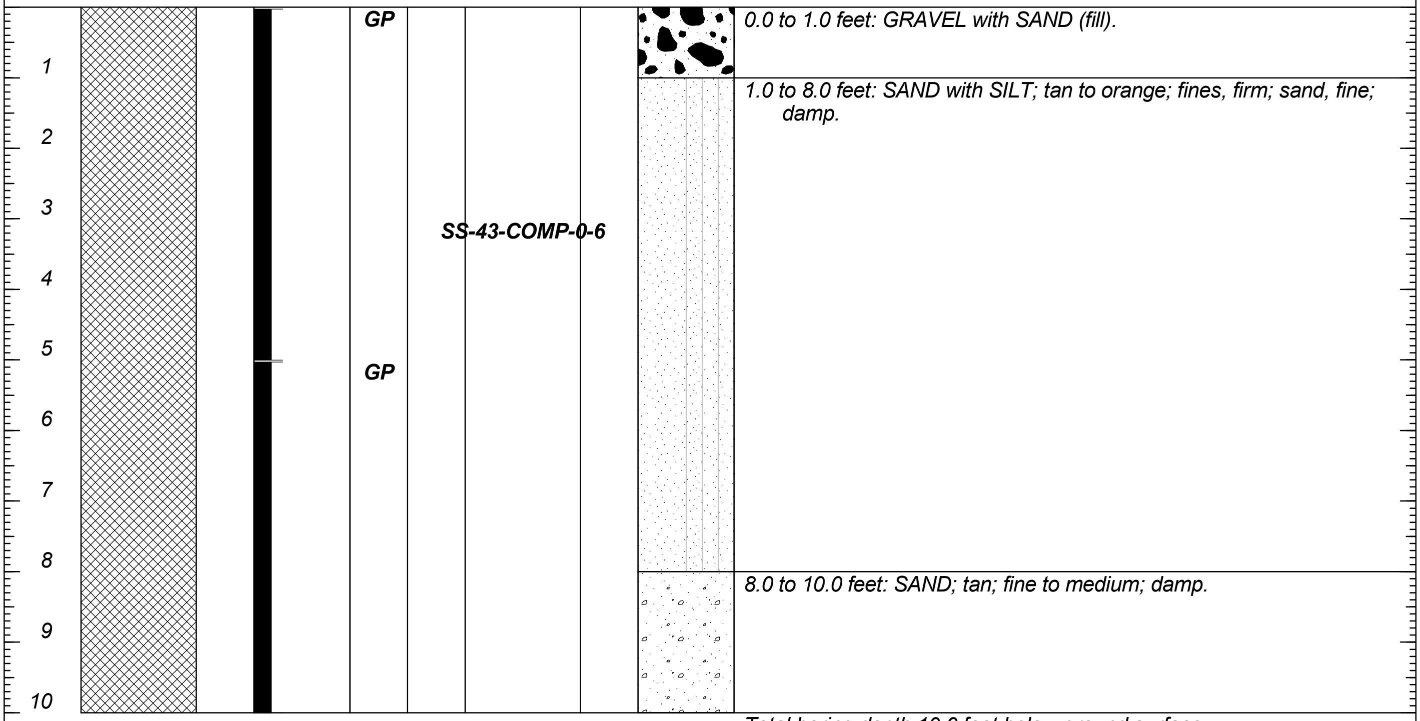
BORING LOGS

Maul Foster & Alongi, Inc.	**Geologic Borehole Log/Well Construction**		
	Project Number ***9003.01.39***	*Well Number* ***SS-43***	*Sheet* ***1 of 1***

Project Name	***Port of Ridgefield***	*TOC Elevation (feet)*	***N/A***
Project Location	***Ridgefield, Washington***	*Surface Elevation (feet)*	
Start/End Date	***9/20/2012 to 9/20/2012***	*Northing*	
Driller/Equipment	***Cascade Drilling, LLC/Geoprobe 6600***	*Easting*	
Geologist/Engineer	***Mike Murray and Phil Wiescher***	*Hole Depth*	***10.0-feet***
Sample Method	***Direct Push***	*Outer Hole Diam*	***2.25-inch***



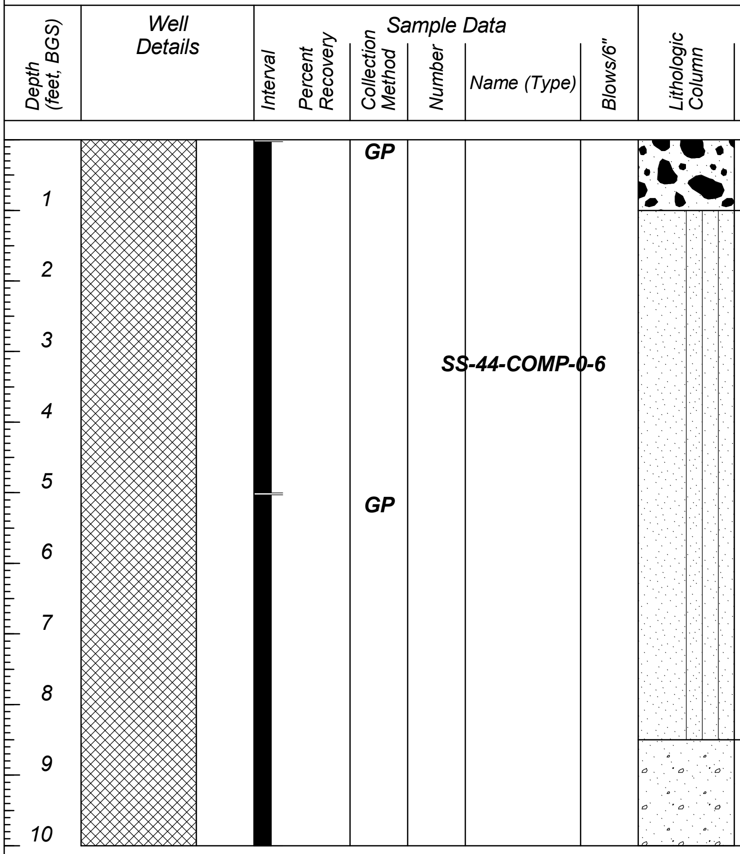
Depth (feet, BGS)	Well Details	Sample Data: Interval	Percent Recovery	Collection Method	Number	Name (Type)	Blows/6"	Lithologic Column	Soil Description
0–1				***GP***		***SS-43-COMP-0-6***			*0.0 to 1.0 feet: GRAVEL with SAND (fill).*
1–8									*1.0 to 8.0 feet: SAND with SILT; tan to orange; fines, firm; sand, fine; damp.*
5				***GP***					
8–10									*8.0 to 10.0 feet: SAND; tan; fine to medium; damp.*

Total boring depth 10.0 feet below ground surface.

NOTES: *(1) Borehole was backfilled with bentonite chips hydrated with potable water. (2) Composite soil sample interval collected between 0.0 and 6.0 feet.*

Maul Foster & Alongi, Inc.	**Geologic Borehole Log/Well Construction**		
	Project Number **9003.01.39**	Well Number **SS-44**	Sheet **1 of 1**

Project Name	**Port of Ridgefield**	TOC Elevation (feet)	**N/A**
Project Location	**Ridgefield, Washington**	Surface Elevation (feet)	
Start/End Date	**9/20/2012 to 9/20/2012**	Northing	
Driller/Equipment	**Cascade Drilling, LLC/Geoprobe 6600**	Easting	
Geologist/Engineer	**Mike Murray and Phil Wiescher**	Hole Depth	**10.0-feet**
Sample Method	**Direct Push**	Outer Hole Diam	**2.25-inch**



Soil Description

0.0 to 1.0 feet: GRAVEL with SAND (fill).

1.0 to 8.5 feet: SAND with SILT; tan to orange; fines, firm; sand, fine; dry.

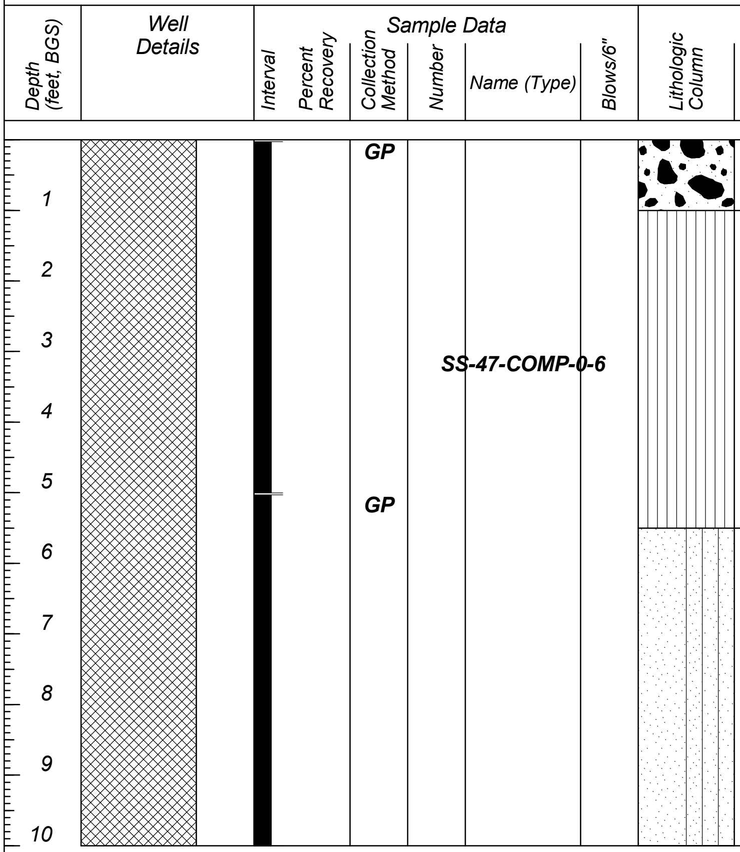
8.5 to 10.0 feet: SAND; tan; fine to medium; firm; damp.

Total boring depth 10.0 feet below ground surface.

NOTES: (1) Borehole was backfilled with bentonite chips hydrated with potable water. (2) Composite soil sample interval collected between 0.0 and 6.0 feet.

Maul Foster & Alongi, Inc.	**Geologic Borehole Log/Well Construction**		
	Project Number	*Well Number*	*Sheet*
	9003.01.39	***SS-47***	***1 of 1***

Project Name	***Port of Ridgefield***	*TOC Elevation (feet)*	***N/A***
Project Location	***Ridgefield, Washington***	*Surface Elevation (feet)*	
Start/End Date	***9/20/2012 to 9/20/2012***	*Northing*	
Driller/Equipment	***Cascade Drilling, LLC/Geoprobe 6600***	*Easting*	
Geologist/Engineer	***Mike Murray and Phil Wiescher***	*Hole Depth*	***10.0-feet***
Sample Method	***Direct Push***	*Outer Hole Diam*	***2.25-inch***



Soil Description

0.0 to 1.0 feet: GRAVEL with SAND (fill).

1.0 to 5.5 feet: SILT; tan to orange; fines, firm; some sand, fine; dry.

5.5 to 10.0 feet: SAND with SILT; fines, firm, medium plasticity; sand, medium; damp.

Total boring depth 10.0 feet below ground surface.

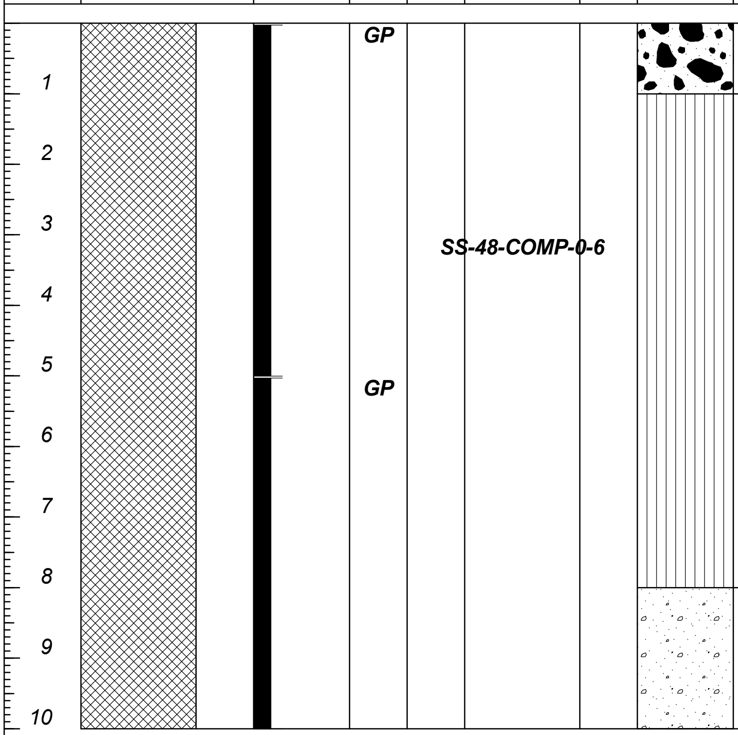
NOTES: *(1) Borehole was backfilled with bentonite chips hydrated with potable water. (2) Composite soil sample interval collected between 0.0 and 6.0 feet.*

Maul Foster & Alongi, Inc.

Geologic Borehole Log/Well Construction

Project Number	Well Number	Sheet
9003.01.39	**SS-48**	**1 of 1**

Project Name	**Port of Ridgefield**	TOC Elevation (feet)	**N/A**
Project Location	**Ridgefield, Washington**	Surface Elevation (feet)	
Start/End Date	**9/20/2012 to 9/20/2012**	Northing	
Driller/Equipment	**Cascade Drilling, LLC/Geoprobe 6600**	Easting	
Geologist/Engineer	**Mike Murray and Phil Wiescher**	Hole Depth	**10.0-feet**
Sample Method	**Direct Push**	Outer Hole Diam	**2.25-inch**



Soil Description
0.0 to 1.0 feet: GRAVEL with SAND (fill).
1.0 to 8.0 feet: SILT; occasional silt to silt/clay inclusions; tan to orange; fines, firm, medium plasticity; trace sand, fine; dry.
8.0 to 10.0 feet: SAND; trace fines, nonplastic, firm; damp.

Total boring depth 10.0 feet below ground surface.

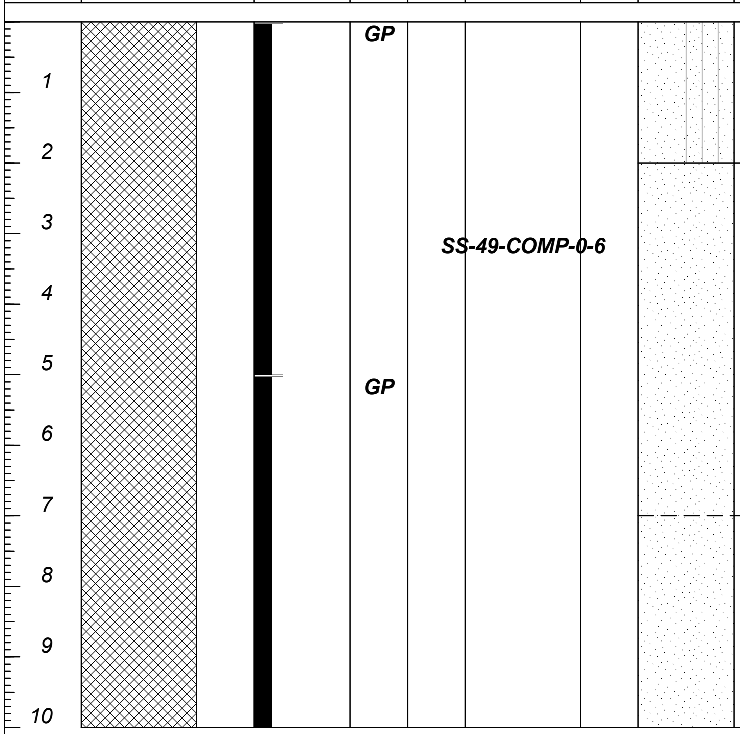
NOTES: (1) Borehole was backfilled with bentonite chips hydrated with potable water. (2) Composite soil sample interval collected between 0.0 and 6.0 feet.

Maul Foster & Alongi, Inc.

Geologic Borehole Log/Well Construction

Project Number	Well Number	Sheet
9003.01.39	**SS-49**	**1 of 1**

Project Name	**Port of Ridgefield**	TOC Elevation (feet)	**N/A**
Project Location	**Ridgefield, Washington**	Surface Elevation (feet)	
Start/End Date	**9/20/2012 to 9/20/2012**	Northing	
Driller/Equipment	**Cascade Drilling, LLC/Geoprobe 6600**	Easting	
Geologist/Engineer	**Mike Murray and Phil Wiescher**	Hole Depth	**10.0-feet**
Sample Method	**Direct Push**	Outer Hole Diam	**2.25-inch**

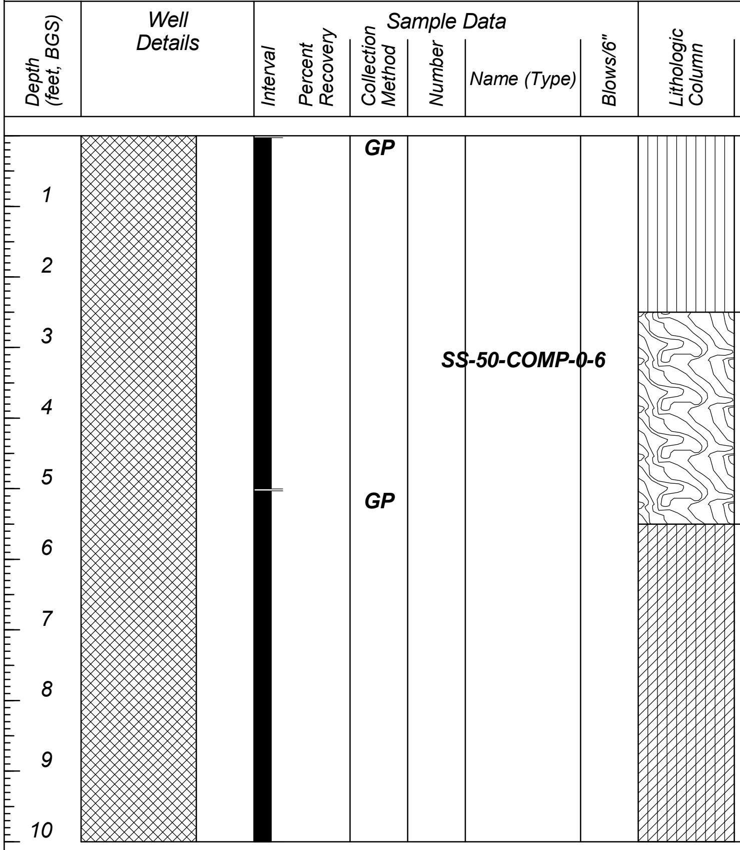


Depth (feet, BGS)	Interval	Percent Recovery	Collection Method	Number	Name (Type)	Blows/6"	Soil Description
0.0			**GP**		**SS-49-COMP-0-6**		0.0 to 2.0 feet: SAND with SILT; tan to orange; fines, loose; sand, fine; dry.
2.0							2.0 to 7.0 feet: SAND; trace fines; sand, medium; damp.
5.0			**GP**				
7.0							7.0 to 10.0 feet: SAND; medium; moist.
10.0							Total boring depth 10.0 feet below ground surface.

NOTES: (1) Borehole was backfilled with bentonite chips hydrated with potable water. (2) Composite soil sample interval collected between 0.0 and 6.0 feet.

Maul Foster & Alongi, Inc.	Geologic Borehole Log/Well Construction		
	Project Number **9003.01.39**	Well Number **SS-50**	Sheet **1 of 1**

Project Name	**Port of Ridgefield**	TOC Elevation (feet)	**N/A**
Project Location	**Ridgefield, Washington**	Surface Elevation (feet)	
Start/End Date	**9/20/2012 to 9/20/2012**	Northing	
Driller/Equipment	**Cascade Drilling, LLC/Geoprobe 6600**	Easting	
Geologist/Engineer	**Mike Murray and Phil Wiescher**	Hole Depth	**10.0-feet**
Sample Method	**Direct Push**	Outer Hole Diam	**2.25-inch**



Soil Description

0 to 2.5 feet: SILT; tan; fines, loose; dry.

2.5 to 5.5 feet: WOOD DEBRIS; fresh; no odor.

5.5 to 10.0 feet: SILT with CLAY; gray; fines, medium plasticity; damp.

Total boring depth 10.0 feet below ground surface.

NOTES: (1) Borehole was backfilled with bentonite chips hydrated with potable water. (2) Composite soil sample interval collected between 0.0 and 6.0 feet.

Maul Foster & Alongi, Inc.	Geologic Borehole Log/Well Construction		
	Project Number **9003.01.39**	Well Number **SS-51**	Sheet **1 of 1**

Subject: January 15, 2013, Supplemental Terrestrial Ecological Evaluation Report.

All,

Ecology reviewed the above referenced report and this e-mail is approval of that document. The referenced report documents the off-property terrestrial ecological evaluation (TEE) work.

The *Supplemental TEE* is already included in an appendix of the redline-strike out version of the *Final Former PWT Remedial Investigation and Feasibility Study* (RI/FS) submitted to Ecology on January 24, 2013 .

Please include this e-mail approval in the same appendix of the RI/FS with the *Supplemental TEE*.

Thank you,

Craig

Re: Final Terrestrial Ecological Evaluation for the Former Pacific Wood Co. Treating Site
Agreed Order No. 01TCPSR-3119

Dear Mr. Rankine:

On behalf of the Port of Ridgefield (Port), Maul Foster & Alongi, Inc. (MFA) has prepared this terrestrial ecological evaluation (TEE) for the Port's Lake River Industrial Site (LRIS, also referred to as "the property") at 111 West Division Street in Ridgefield, Washington. Historical operations of Pacific Wood Treating Company on the LRIS resulted in wood-treating chemical impacts to soil and groundwater. Remedial investigations (RIs) and feasibility studies (FSs) are being performed to evaluate and manage site-related chemical impacts to soil and groundwater. The RI/FSs will be completed in accordance with the requirements of the Model Toxics Control Act (MTCA) and the Agreed Order No. 01TCPSR-3119 entered between the Washington State Department of Ecology (Ecology) and the Port.

A TEE was included in the draft RI/FS report for Cell 4 (MFA, 2009). Ecology has requested a more expansive TEE that addresses the entire LRIS, not just Cell 4.

A site-specific TEE for the entire LRIS was performed following the procedures outlined in Washington Administrative Code (WAC) 173-340-7490 and WAC 173-340-7493. The purpose of this TEE is to present sufficient information to evaluate the ecological protectiveness of the remedial alternatives being evaluated for the LRIS (see WAC 173-340-7490(1)(b)). The TEE includes problem formulation and an ecological screening evaluation (WAC 173-340-7493(1)(c)).

In addition to evaluating the TEE, this letter assesses the ecological protectiveness of a soil cap proposed for the LRIS. As described in the draft FS reports for Cell 3 (MFA, 2008) and Cell 4 (MFA, 2009), a cap will be part of the recommended interim remedial action to protect human health. The cap over contaminated soil can also protect potential future ecological receptors. Different cap options for the property are discussed in this report. This proposed interim remedial action is also consistent with recommended options discussed with Ecology.

This site specific TEE demonstrates that a future soil cap for the site, along with the proper institutional controls and monitoring, will protect ecological receptors and meets the purpose and requirements of WAC 173-340-7490, such that no additional ecological protective measures will be necessary.

PROBLEM FORMULATION

One of the early steps in any ecological evaluation is problem formulation (U.S. Environmental Protection Agency [USEPA], 1998). Problem formulation involves identifying chemicals of ecological concern (CECs), describing pathways by which ecological receptors may contact CECs in soil, and identifying current or potential future terrestrial ecological receptors that may contact soil (WAC 173-340-7493(2)). The conceptual site model (CSM) and other aspects of problem formulation are described below.

Conceptual Site Model

The LRIS CSM describes potential chemical sources, release mechanisms, environmental transport processes, exposure routes, and receptors. The primary purpose of the CSM is to describe pathways by which terrestrial ecological receptors could be exposed to CECs in soil. A complete exposure pathway consists of four necessary elements: (1) a source and mechanism of chemical release to the environment, (2) an environmental transport medium for a released chemical, (3) a point of potential contact with the impacted medium (referred to as the exposure point), and (4) an exposure route (e.g., soil ingestion) at the exposure point.

Sources

The LRIS was used to treat lumber and to store both treated and untreated wood. Historical wood-treating activities were conducted primarily in Cell 1. Cell 2 was used for fabrication; Cell 4 was historically used to store untreated poles and green lumber before treatment with wood preservatives; and Cell 3 was used to store treated wood. Accidental releases of wood-treating chemicals occurred as part of treatment operations and during storage of treated wood. It appears that wood-treating chemicals were transported on the tires of vehicles throughout most of the LRIS. As a result, soil in much of the LRIS has elevated concentrations of some wood-treating chemicals.

Fate and Transport

The primary mechanisms that influence the fate and transport of chemicals in soil include natural biodegradation of organic chemicals, sorption to soil, redistribution due to vehicle tracking, and leaching of chemicals from soil to groundwater. In some areas of the LRIS, nonaqueous-phase liquid is present in the subsurface and has caused impacts to both soil and groundwater.

Setting

The LRIS was formerly an industrial property that was first used for industrial purposes in the early 1900s. The Port currently restricts public access to much of the LRIS, and the property is largely unused. The LRIS is zoned by the City of Ridgefield for waterfront mixed use. Under this classification, allowed uses include ground floor commercial with upper story living units; retail, restaurants and lodging; and service industries. The City of Ridgefield zoning of the LRIS is consistent with the Port's plans for redevelopment of the property.

Currently, gravel, pavement, and buildings cover most of the LRIS, creating unsuitable substrate for most native plants. Because activity on the property has been low in the recent past, some mostly nonnative invasive plants (e.g., Himalayan blackberry) capable of growing in highly disturbed substrate have become established in some graveled areas. The density and diversity of plants are low. The property is devoid of significant ecological habitats (Ecological Land Services, Inc. [ELS], 2007), and would otherwise have qualified for an exclusion under the Simplified TEE procedures (WAC 173-340-7492) if not for the presence of the adjoining Ridgefield National Wildlife Refuge (RNWR). While it is possible for wildlife to visit the site, because there are no important resources for wildlife (little natural food or cover), potential exposures to impacted soil would be minimal.

Chemicals of Ecological Concern

Wood-treating chemicals detected in soil at concentrations greater than the ecological indicator concentrations given in MTCA Table 749-3 are considered CECs (WAC 173-340-7493(2)(a)(i)). According to WAC 173-340-7490(3)(b), the Table 749-3 ecological indicator concentrations for industrial or commercial sites are those for terrestrial wildlife unless threatened or endangered plant or invertebrate species are present. Because the property was used for industrial purposes for nearly a century, is currently zoned for waterfront mixed use, is planned for redevelopment that will support commercial operations (see Attachment A), and does not support threatened or endangered plants or invertebrates (ELS, 2007; MFA, 2007), only Table 749-3 ecological indicator concentrations for wildlife were used to identify CECs. Attachment B is ELS's habitat evaluation for the property.

The wood-treating chemicals identified in soil include metals (arsenic, chromium, copper, and zinc), diesel, pentachlorophenol (PCP), polycyclic aromatic hydrocarbons (PAHs), and dioxins/furans. With a few exceptions, wildlife screening levels are available in MTCA Table 749-3 for all of these wood-treating chemicals. For example, both creosote and diesel were used as part of historical site operations, and these products may contain several different PAHs. Ecological indicator concentrations for wildlife are presented in Table 749-3 with numeric values for key PAHs (i.e., those that are common, well-studied, and/or relatively toxic).

Two forms of inorganic arsenic are common in the environment: trivalent arsenic (arsenite or As III), and pentavalent arsenic (arsenate or As V). Arsenate is more common under oxidizing conditions and is more stable and less toxic. Arsenite is more prevalent under reducing conditions and is more toxic. For a variety of reasons, that most of the anthropogenic arsenic in soil of the LRIS is arsenate. First, the common wood-treating solutions that include arsenic such as chromate copper arsenate and ammoniacal copper zinc arsenate contain the arsenate species. Therefore, mainly arsenate, and not arsenite, was the form of arsenic accidentally released at the site. Also, surface soil at the LRIS is likely oxidizing, so the arsenate species is the predominate species present in surface soil. The Table 749-3 wildlife indicator concentration for arsenate is substantially higher than the value for arsenite. However, to be conservative, this TEE uses the wildlife indicator concentration for arsenite even though this will result in overestimates of potential risks to wildlife.

Table 749-3 gives separate ecological indicator concentrations for total dioxins and total furans. These MTCA screening values have remained unchanged since at least 2003, and do not reflect recent updates in how Ecology evaluates the toxicity of dioxin and dioxin-like compounds (Ecology, 2007a,b; USEPA, 2008; Van den Berg et al., 2006). The current Ecology evaluation method recognizes that dioxins and dioxin-like substances (i.e., furans) have a common mode of action, and the toxicity of mixtures of these types of chemicals are estimated by summing the relative toxicities of various congeners in the mixture (Ecology, 2007b; USEPA, 2008; Van den Berg et al., 2006). As a result, the wildlife indicator values of 2E-06 milligrams per kilogram given in Table 749-3 for both chlorinated dibenzofurans and for chlorinated dibenzo-p-dioxins are not comparable to the toxicity equivalent concentrations given in Table 1. Ecology recognizes that the Table 749-3 values are inappropriate, and is considering changing them to reflect current standards (Ecology, 2009). Instead of using inappropriate wildlife screening values that will be corrected by Ecology in the near future, this TEE uses updated ecological screening levels for dioxins/furans that were recently developed for another site in western Washington (Malcolm Pirnie, 2007). The updated ecological screening values are based on empirical data for biota of western Washington where each dioxin or furan was measured in colocated soil and biota samples, and were calculated using current Ecology guidance for estimating toxicity of dioxins and furans (Malcolm Pirnie, 2007). The lowest wildlife indicator value for 2,3,7,8-tetrachloro dibenzo-p-dioxin (TCDD) was 182 nanograms per kilogram for voles (Malcolm Pirnie, 2007).

Ecological Screening

The ecological screening evaluation was performed to identify locations where wood-treating chemicals in soil were found at concentrations greater than the ecological indicator concentrations from Table 749-3. As mentioned previously, chemicals with concentrations above these values are considered CECs. Table 1 compares chemical concentrations in soil with ecological indicator concentrations for metals, PCP, benzo(a)pyrene, dioxins, and petroleum hydrocarbons that are listed in Table 749-3. The ecological screening evaluation was performed to identify chemicals in soil with concentrations greater than the ecological indicator concentrations from Table 749-3.

For the purposes of this screening evaluation, all soil data collected throughout the LRIS for the above CECs were included in Table 1. Some of the soil samples were collected almost two decades ago and it is likely that soil conditions have improved over time. For example, remedial actions such as soil removal and steam-enhanced extraction have likely decreased concentrations in soil, and natural biodegradation has also likely reduced concentrations of some organic chemicals in soil. Therefore, the ecological screening evaluation is considered conservative.

Seven chemicals were detected in soil above the ecological indicator concentrations and are considered CECs: arsenic, chromium, copper, zinc, benzo(a)pyrene, dioxins/furans, and PCP (Table 1). The nature and extent of CECs in Cells 3 and 4 have been discussed in previous reports (MFA, 2007, 2009). The nature and extent of CECs in soil of Cells 1 and 2 will be presented in an upcoming report(s). Based on a visual inspection of data in Table 1, it appears that CECs in soil have a heterogeneous spatial distribution. In general, only soil near the surface had CEC concentrations above background levels. With a few exceptions, concentrations of CECs in soil more than approximately 2.5 feet below ground surface were similar to background concentrations.

REMEDY EVALUATION

Concentrations of wood-treating chemicals in soil are above MTCA Method B cleanup levels, background levels, and Table 749-3 ecological indicator concentrations at several locations in the LRIS. Because concentrations exceed MTCA cleanup levels, there is an unacceptable risk for humans and ecological receptors at the LRIS. Therefore, remedial actions are necessary to address both human health and ecological risk.

A capping remedy is proposed to address direct contact, uptake and ingestion by both human and ecological receptors. The purpose of the cap is to prevent future occupants from directly contacting chemicals by creating a physical exposure barrier. The proposed cap profiles, based on land use, are as follows:

Cap Profiles	
Type of Use	Typical section
Landscaping	See landscaping cap profiles below.
Parking	Impermeable surface (min. thickness 3 in.) with clean sub-base as necessary for construction
Building/structure	Slab-on-grade (min. thickness 3 in.) with sub-base as necessary for construction
Sidewalk/pathway	Impermeable surface (min. thickness 3 in.) with clean sub-base as necessary for construction

Based on land use plans, the LRIS will be redeveloped to support commercial activities. If an existing cap is disturbed during development, an equally protective cap will be installed based on the intended use of the area, in accordance with a soil management and cap maintenance plan.

The planned development will include landscaped areas (see Attachment A). Although these do not represent significant ecological habitat for native wildlife, Ecology requested an evaluation of how wildlife could be exposed to contamination below an engineered soil cap in landscaped areas. As discussed below, the proposed cap profiles for landscaped areas will be protective of ecological receptors.

Engineered Soil Cap

The type of cap used in any particular place depends on future development of the site. For example, in some areas the cap may comprise relatively impermeable features such as a building foundation or parking area made of asphalt or concrete. For the purposes of evaluating the ecological protectiveness of a soil cap, it is assumed that the soil cap will consist of a geotextile liner beneath a minimum of 2 feet of clean soil. The geotextile liner will serve as a demarcation layer indicating the bottom of the soil cap, and it will prevent upward migration of fine-grained material while enhancing the barrier effect of the overlying soil cover. A geotextile (SKAPS GT-160 Nonwoven Geotextile™ or equivalent) has an apparent opening size of 0.21 millimeter, which allows for surface water infiltration and avoids creation of a hydraulic barrier while providing negligible pathways for ecological receptors. Additionally, this geotextile has a puncture strength of 90 pounds, minimizing root penetrations. The nonwoven geotextile to be used in the capping will be a polypropylene material. Polypropylene materials typically are subject to degradation by ultraviolet light, but as the material will not be exposed before installation and will be covered with a soil cap following installation, the ultraviolet light degradation will be minimized. According to the manufacturer, the SKAPS geotextile resists ultraviolet deterioration, rotting, biological degradation, and naturally encountered bases and acids.

At the request of Ecology, the cap will be planted with species that have shallow root systems. Attachment C presents some of the plant species that may be planted in the cap areas. Grasses and shallow-rooted ground cover plants are preferred in areas with 2 feet of soil capping. Grasses and shallow-rooted trees and shrubs are preferred in areas with 3 feet of soil capping. No geotextile liner or landscaping restrictions are proposed for soil capping greater than 6 feet. Cover over the soil cap could also include gravel surfaces for roadways or paths. In addition, as part of the soil management and cap maintenance plan, inspection and maintenance of landscaping will be included.

In accordance with Ecology's recommendation, the proposed cap profiles for protection of ecological receptors in landscaped areas, based on soil cap thickness, are as follows:

Landscaping Cap Profiles

Cap Soil Thickness	Additional Cap Components/Restrictions
<2 feet	Geotextile as demarcation; no landscaping; impermeable surface required (e.g., pavement and buildings)
2 to 3 feet	Geotextile as demarcation layer; ground cover as outlined in Attachment C, gravel surfaces, or additional as approved by Ecology, any grasses
3 to 6 feet	Geotextile as demarcation layer; shrubs or trees as outlined in Attachment C, gravel surfaces, or additional as approved by Ecology, any grasses
>6 feet	No geotextile and no vegetation planting restrictions

Although only shallow-rooted plants are proposed for areas where the soil cap is less than 6 feet thick, as described in greater detail below, the proposed soil cap will be protective of terrestrial ecological receptors regardless of the rooting depths of plants on the cap.

Institutional controls will also be used in conjunction with the cap as part of the remedial action. The institutional controls will be in the form of a restrictive environmental covenant requiring adherence to a soil management plan and monitoring to ensure acceptable performance in the future. The soil management plan will outline methods for protecting and maintaining the surface cap and managing residual contaminated soils during redevelopment or subsurface work. A restrictive covenant will also be implemented to prohibit the use of groundwater for drinking, and prevent installation of a water well that could influence groundwater flow and affect the dynamics of contaminant plumes. A cap monitoring program will be implemented to aid in the identification and repair of breaches in the cap.

Potential Future Ecological Receptors

When considering ecological receptors that may be exposed to soil contamination, it is very important to distinguish between current and proposed future conditions that will exist after a cap has been established. Under current conditions, terrestrial wildlife could visit the property and an individual bird or mammal could have incidental exposure to chemicals in soil. Given the poor habitat conditions, current site use by humans (e.g., the adjoining Marina, public boat ramp, and miscellaneous Port activities), and the lack of significant wildlife resources, local populations of birds and mammals will not have sufficient exposure to impacted soil to result in adverse effects. However, current conditions are less relevant than future conditions for evaluating ecological protectiveness of a cap. If the current soil surface were to be capped with 2 feet of clean soil, most wildlife would be unable to directly contact chemicals in the subsurface. Of the wildlife in the region, only a few species have physical attributes or behaviors that would allow them to penetrate 2 feet of soil. The future plantings in landscaped areas are not considered ecologically significant habitat under MTCA regulations (see WAC 173-340-7491(2)(c)(ii)).

According to the U.S. Fish and Wildlife Service species list for the RNWR (USFWS, 2009), biological surveys at the refuge have identified two mammals that routinely develop burrow systems that could extend more than 2 feet below the ground surface in upland habitats (not stream banks): Townsend mole (*Scapanus townsendii*) and California ground squirrel (*Spermophilus beecheyi*). Voles sometimes construct shallow burrows, but these rarely extend more than a few inches below the surface (Maser, 1998). Coyotes may construct underground dens, and other wildlife on the refuge may occasionally use burrows constructed by other species. However, species other than the Townsend mole and California ground squirrel are unlikely to have significant regular exposures to subsurface soil.

The Townsend mole is an invertivore that feeds primarily on earthworms in the subsurface. These moles tend to develop shallow burrows and prefer moist areas with deep friable soil (Maser, 1998). The LRIS does not support moles, and moles will not have significant exposure to contaminants after a soil cap is constructed. Based on visual inspections, soil over most of the LRIS appears compacted. Heavy vehicles have operated over most of the LRIS for decades, and soil was likely graveled and compacted to support industrial operations. Chemicals are located in highly compacted soil that has not supported significant plant growth in decades. As a result, impacted soil does not offer important food resources for earthworms, which forage primarily on decomposed plant materials. Also, compacted soil is not preferred by either earthworms or moles because it is relatively difficult for burrowing animals to move through. Because the compacted soil does not provide good habitat for earthworms, it will not offer significant resources for moles. However, if the soil cap is revegetated in the future, earthworms may colonize the cap to feed on decomposed plant materials, and moles may then follow. Moles that may forage in the soil cap are unlikely to have significant exposure to contaminants because their diet will comprise of earthworms that reside in the soil cap and are uncontaminated.

California ground squirrels, also known as Beechey ground squirrels, are omnivorous rodents that forage primarily on aboveground plant materials. They may develop extensive burrow systems, which are used during hibernation and to escape predators (Maser, 1998). These squirrels are relatively recent invaders in Washington. They appear to have traveled on bridges built over the Columbia River in the early 1900s, and have now settled into areas of south-central Washington. In general, California ground squirrels forage in close proximity to their burrows (within approximately 100 feet). Therefore, unless the landscaping on the future soil cap contains a sufficient density of edible plants, the cap will not be colonized by ground squirrels. Most landscaped features on commercial sites in western Washington are structurally simple (e.g., lawns, ornamental trees and shrubs, perennial showy flowers) and do not represent significant food resources for ground squirrels.

In summary, two mammal species in the area near the LRIS are known to frequently develop and inhabit burrows, and in some cases these burrows can extend more than 2 feet below the ground surface. However, for a variety of reasons, the likelihood that several individuals of either species would colonize the cap is low. The typical landscaping at commercial properties does not offer important food resources for either species. Also, the relatively small size of the landscaped area and the high frequency of human disturbance associated with many commercial areas may make the site unattractive to burrowing mammals.

The cap monitoring program will include regular inspections for burrowing mammals. Provisions will be included in the cap monitoring program that call for the removal of burrowing mammals if they are discovered on the cap.

Indirect Ecological Exposure Scenarios

There are two potential scenarios by which wildlife could potentially have indirect exposure to chemicals in subsurface soil beneath a cap. First, it is theoretically possible that burrowing invertebrates such as earthworms could dig through the cap, ingest impacted soil, migrate back up to the top of the cap, and be caught and consumed by wildlife. Similarly, it is theoretically possible that some plants could develop roots that grow into the soil beneath the cap, uptake contaminants from soil, and then translocate contaminants to plant parts that are consumed by wildlife. As discussed below, neither of these theoretically possible ecological exposure scenarios will lead to significant exposures for wildlife that could visit future landscaped areas. Note that the purpose of limiting the plant species in the soil cap is to minimize the risk of this theoretical possibility.

As mentioned previously, the impacted soil now present at the property does not offer important food resources for populations of earthworms or other soil invertebrates. Soil is compacted, making it difficult for worms to move through, and because no significant plant community has been present for decades, the soil will not contain significant organic material that make up the diet of worms. After plants are established on a soil cap, it will be colonized by worms and other invertebrates that feed on plant materials in the cap.

CEC migration from soil into aboveground foliage will not recontaminate the cap. First, at the request of Ecology, plants with shallow root systems will be planted on the soil cap. In mesic environments such as western Washington, most native plants have shallow root systems designed to capture precipitation and nutrients that infiltrate from the ground surface. Root density for almost all plants decreases exponentially with depth. In ecological risk assessments, 30 centimeters (approximately 12 inches) has often been used as a default estimate of the depth below which plant root exposure to contaminants is insignificant (Suter, 2007). The proposed cap will be at least twice as thick as this default rooting depth estimate (Suter, 2007).

In general, chemicals that migrate from subsurface soil into aboveground plant structures (e.g., leaves) first dissolve from soil into soil pore water, and are then taken up by roots (McKone and Maddalena, 2007). They can be transported from roots to leaves in the dissolved phase through either transpiration or translocation. Plant uptake of chemicals from soil is determined by numerous factors such as the species of plant, soil type, pH in soil, organic carbon content of soil, temperature, and nutrient levels. The primary organic CECs in soil include PCP, PAHs, and dioxin/furans. Organic compounds with high molecular weights (e.g., dioxin/furans, PAHs, PCP) are relatively insoluble and plant uptake of these chemicals is low (Travis and Arms, 1988; McKone and Maddalena, 2007)

Plant uptake factors (PUFs) for aboveground plant parts are typically defined as the ratio of the chemical concentration in the plant over the concentration in soil (expressed as dry weight). Travis and Arms (1988) found that a PUF was associated with the logarithm of the octanol-water partition coefficient (log K_{ow}) for a chemical. The K_{ow} is a measure of chemical solubility. The following equation can be used to estimate conservative PUFs for organic chemicals (Travis and Arms, 1988):

$$\log PUF = 1.588 - 0.578 \log K_{ow}$$

The log K_{ow} and the calculated PUF is given in Table 2 for four representative CECs (i.e., highest frequency of exceedances of screening levels and/or highest relative toxicity of CECs) in soil: benzo(a)pyrene, 2,3,7,8-TCDD, and PCP. The estimated PUFs range from approximately 0.005 to 0.016, indicating that the concentrations of chemicals in aboveground plant parts would be approximately two orders of magnitude lower than concentrations in soil. It should be noted that conservative PUFs typically overestimate chemical concentrations in plant leaves due to translocation from roots (Efroymson et al., 2001). Relative to other processes by which plant leaves may accumulate chemicals (e.g., air-to-plant accumulation processes), plant root uptake and translocation of high-molecular-weight chemicals such as dioxins are insignificant (IOM, 2003). Similarly, concentrations of PAHs in plants due to root uptake are substantially lower than soil concentrations, and foliar herbivory does not appear to be a significant pathway by which wildlife may be exposed to PAHs in the environment (USEPA, 2009).

As with organic chemicals, plant uptake of inorganic chemicals such as arsenic can be complex. Factors that affect plant uptake of arsenic include reduction and oxidation conditions, the species of arsenic, plant types, pH, and phosphate levels. Two separate evaluations of conservative PUFs for arsenic estimated a value of approximately 0.04 (Baes et al., 1984; Efroymson et al., 2001). Plant translocation of arsenic from soil to aboveground parts is minor for most settings, and concentrations in plant parts are expected to be about two orders of magnitude lower than concentrations in soil. It should be noted that arsenic occurs naturally in plants, but concentrations of arsenic in plant parts are typically ten to 1,000 times lower than concentrations in soil (Eisler, 1988).

To evaluate the effect on wildlife from potential bioaccumulation of CECs in plants, conservative PUFs were applied to mean soil concentrations (see Appendix D) to estimate CEC concentrations in aboveground plant parts that wildlife may contact. Although this evaluation was not performed to demonstrate compliance, statistical methods consistent with WAC 173-340-740(7)(c)(iv)(B) were used to estimate CEC concentrations in soil (Table 2). Specifically, the 95 percent upper confidence limit about the mean concentration (95% UCL) of a CEC in soil was used as the soil exposure point concentration. The 95% UCL is a value that has a 95 percent probability of being greater than the true population mean. The 95% UCL provides an estimate of the population mean that is biased on the high side to account for the uncertainty introduced by extrapolating from a sample to the population. The USEPA statistical software ProUCL 4.00.04 was used to calculate 95% UCLs for CECs. The statistical methods used in this USEPA software program are more appropriate than many of the methods described in WAC 173-340-740(7), which is now outdated. The output from ProUCL is presented as Attachment D.

As shown in Table 2, conservative estimates of future CEC concentrations in plants growing in impacted soil are below wildlife ecological indicator concentrations. Therefore, even if no protective soil cap was placed over contamination, CECs would not significantly bioaccumulate in aboveground plant parts. Concentrations in plants on a clean cap will be lower than these conservative estimates because few plant roots will extend into the contaminated soil layer. Therefore, the proposed engineered cap remedy will be protective of terrestrial wildlife that could visit landscaped areas in the future.

Summary

A soil cap with a minimum thickness of 2 feet has been proposed for the LRIS to protect human health. All available evidence suggests that this type of cap is also protective of ecological receptors. Most wildlife that could visit the surface of the cap would be incapable of penetrating the cap (e.g., birds, mice). Given the commercial nature of the property, the future landscaped cap will not provide good habitat. Contaminated soil beneath the future cap will not pose a risk to wildlife that may visit the future landscaped areas at the LRIS.

Table 1 Notes
Lake River Industrial Site

-- = not analyzed.

Bold number indicates detected concentration that exceeds screening criteria.

feet bgs = feet below ground surface.

H = sample analyzed outside recommended holding time.

J = estimated concentration.

K_{ow} = octanol-water partitioning coefficient.

mg/kg = milligrams per kilogram (parts per million).

MTCA = Model Toxics Control Act.

µg/kg = micrograms per kilogram (parts per billion).

NA = not available.

ng/kg = nanogram per kilogram (parts per trillion).

PCP = pentachlorophenol.

PHC = petroleum hydrocarbons.

PUF = plant uptake factor, calculated using equation in report.

TCDD = tetrachloro dibenzo-p-dioxin.

U = not detected at or above method reporting limit.

UH = not detected at or above method reporting limit, but sample was analyzed outside recommended hold time.

UCL = upper confidence limit, calculated using ProUCL (see Attachment D).

Z = analyte detected, but its chromatographic fingerprint does not resemble a petroleum product.

[a] Used arsenic III (arsenite) value of 7 mg/kg, not arsenic Vi (arsenate) value of 132 mg/kg.

[c] Residual saturation also has to be considered.

[d] Value is outside control criteria.

Table 2
Plant Uptake
Lake River Industrial Site

Chemical	log K_{ow} [A]	PUF [B]	95% UCL of Mean [C] (µg/kg)	Concentration in Plants [D] (µg/kg)	Wildlife Screening Value [E] (µg/kg)
Benzo(a)pyrene	6.1	0.0115	4303	4.97E+01	1.20E+04
2,3,7,8-TCDD	6.8	0.0045	1.463	6.65E-03	1.82E-01
PCP	5.86	0.0159	39700	6.31E+02	4.50E+03
Arsenic	NA	0.04	21590	8.64E+02	7.00E+03

Notes:

A. log octanol/water partitioning coefficient (K_{ow}) from USEPA 2004.

B. Plant uptake factor (PUF) for organics from Travis and Arms, 1988; PUF for arsenic from Efroymson et al., 2001.

C. 95 percent upper confidence limit (UCL) about the mean from Appendix D. All concentrations have been converted to micrograms per kilogram (ug/kg).

D. Conservative estimate of the concentration in above-ground plant parts = PUF * 95% UCL.

E. MTCA Table 749-3 ecological indicator concentration for wildlife (see Table 1).

HABITAT EVALUATION

ECOLOGICAL LAND SERVICES, INC.

November 13, 2007

Todd Johnson
Group Mackenzie
601 Main Street, Suite 101
Vancouver, Washington 98660

Re: Habitat Evaluation for the Port of Ridgefield Lake River Site; ELS Project # 1268.04

Dear Mr. Johnson:

Enclosed are 5 copies of the Habitat Evaluation Report for the Port of Ridgefield Property adjacent to Lake River within Sections 13 and 24 of Township 4 North, Range 1 West, W.M.

While there are no critical area buffers on-site, it is likely that in the future, a No Effect determination may need to be made to comply with WDFW standards.

If you have any questions or I may be of further assistance, please feel free to contact me at (360) 578-1371.

Sincerely,

Lisa F. Willis

TABLE OF CONTENTS

FIGURES

APPENDIX A

INTRODUCTION

Ecological Land Services, Inc. (ELS) performed a Critical Areas evaluation and a riparian habitat inventory for Group Mackenzie as required by Ridgefield Municipal Code (RMC 18.280) for the potential redevelopment of the former Pacific Wood Treatment Company site and a portion of the current City of Ridgefield sewage treatment facility property. The 42.93 acre site (Table 1) is located at 109 and 111 West Division Street, Ridgefield, Washington, in a portion of Section 24, Township 4 North, Range 1 West of the Willamette Meridian. Group Mackenzie proposes to redevelop the site for multiple uses with a hotel, retail space, office space, public open space, and a pedestrian walkway along the Lake River shoreline.

Table 1: Subject Parcel Account Numbers, Owners, and Land Area

Parcel	*Owner*	*Acres*
219386-000	Port of Ridgefield	4.23
068360-000	Port of Ridgefield	5.78
068362-000	City of Ridgefield	0.44
068354-000	City of Ridgefield	1.32

067998-000	Port of Ridgefield	0.21
067883-000	Port of Ridgefield	0.29
	Approximate Total	**42.93**

SITE DESCRIPTION

The subject site consists of an estimated 42.93 acres located immediately south of the Carty Lake Wetland within the Ridgefield National Wildlife Refuge, east of Lake River, and west of downtown Ridgefield, Washington. The site is bordered by Burlington Northern railroad to the east, a small public marina to the south, Lake River to the west, and Ridgefield National Wildlife Refuge to the north.

Multiple buildings and structures associated with the former Pacific Wood Treatment Company located in the northern and central region of the property will be demolished in preparation for future development (Figure 2). Historic photographs show that virtually all surface area on-site not currently or previously covered by buildings is covered with gravel or pavement or was previously filled, continuing up to approximately 10 to 20 linear feet from the Line of Mean High Tide (Figures 2, 2A). The site is generally flat topographically, with steep slopes into Lake River to the west (Figure 2B).

The property was used as a wood processing and shipping site between 1963 and 1993. Contaminants were discovered in an approximately four acre area in the central-northeastern region of the site in 1985. A steam enhanced remediation project has been in process since 2004.

The clean-up project is being carried out by Port of Ridgefield personnel and overseen by the Washington Department of Ecology.

The on-site banks of Lake River slope at approximately 30 to 70 percent and are loosely covered with rip-rap and erosion control gravel. Treated lumber retaining walls are located at the northern and northeastern site boundaries adjacent to the National Wildlife Refuge (NWR; Figure 2B). A former dock and ship loading area are located in the southern region of the site on the riverbank. The loading area is constructed of treated lumber acting as a retaining wall. A fire emergency irrigation pump is located on piles at the northwestern extreme of the property beyond the OHWM. A number of abandoned piles are located beyond the OHWM of Lake River (Figure 2). The area between the OHWM of Lake River and paved surfaces is heavily vegetated, primarily with non-native herbaceous and scrub-shrub plants including California false indigo and Himalayan blackberry, and native trees including black cottonwood and Douglas-fir.

METHODS

Historic and current photographs dating back to 1929 were studied in order to determine the extent of historic disturbance on the site (see Appendix A). A site reconnaissance of the property was conducted by ELS on August 23, 2007 with focus to the western and northern boundaries. The western and northern property boundaries are located adjacent to critical habitat areas, or areas of concern. The current habitat functions within these off-site areas were assessed by ELS. Riparian functions on-site were rated qualitatively using the Clark County Habitat Conservation Ordinance Riparian Habitat Field Rating Form.

Significant trees along the river banks were located and surveyed by Barbieri and Associates, Inc. Only those trees that were six inches or greater in diameter at breast height (dbh) were counted. Trees and shrubs isolated by gravel or paved pads were not counted due to their lack of available habitat. Edges of gravel and pavement as well as existing buildings were also surveyed (Figure 2).

The OHWM of Lake River was not flagged as it was not needed to establish the buffer on-site. The line of Mean High Tide (MHT) was used in place of the OHWM due to the tidal nature of Lake River and the similarity in location of the OHWM and MHT. The existing eastern buffer of Lake River along the project site is functionally isolated by fill, impervious surfaces, and structures (*RMC 18.280.030(B)(2))*. The proposed re-development of the project site will not increase the impervious surface area within the Riparian Management Area or Riparian buffer; therefore, no riparian buffers will be required to extend on-site across the functionally isolated boundary. See "Edge of Gravel as Surveyed" boundary line, Figure 2.

The off-site Carty Lake Wetland located within the National Wildlife Refuge north of the project site was inventoried from the Port Property and aerial photography.Functions for the off-site wetland were assessed using the Wetland Rating Form for Western Washington (DOE 2004). The existing on-site buffer located south of the Carty Lake Wetland is functionally separated from the wetland and does not protect the wetland from adverse impacts. Therefore, a wetland buffer will not be required to extend on-site across the functionally isolated boundary (*RMC 18.280.150.(C)(ii)(f)).* See "Edge of Gravel as Surveyed" boundary line, Figure 2.

SOILS

Soils on-site are mapped as Hillsboro silt loam, 8 to 15 percent slopes (HoC), Hillsboro silt loam, 15 to 20 percent slopes (HoD), Hillsboro silt loam, 30 to 65 percent slopes (HoG), and Sauvie silt loam, 3 to 8 percent slopes (SmB), according to Natural Resource Conservation Service Web Soil Survey Data (NRCS 2007).

Hillsboro silt loam soils are well drained soils formed from alluvium and found on terraces. Sauvie silt loam soils are moderately well drained soils formed from alluvium and found on flood plains. The majority of the soils mapped on-site are Sauvie silt loam (Figure 3). None of the soils mapped on-site are listed as hydric soils by the NRCS (2007).

Soils on-site are significantly disturbed and consist mainly of fill placed prior to 1963. Native soils are not likely to be encountered on-site within the upper two feet of the soil profile adjacent to Lake River.

VEGETATION

Vegetation on-site is generally restricted to the area between MHT and the line of impervious surface. Vegetative cover along the shoreline on-site was dense, predominantly consisting of California false indigo (*Amorpha fruticosa*), Himalayan blackberry (*Rubus armeniacus*), Pacific willow (*Salix lucida*), Douglas fir (*Pseudotsuga menziesii*), and black cottonwood (*Populus balsamifera*). Dominant shrub species on-site were non-native, invasive species. The canopy is composed of mature native species.

Washington State Priority Species

The Washington Department of Fish and Wildlife considers Oregon White Oak (*Quercus garryana*) a protected species (Habitats and Species Report October, 2006). There are protected populations of these trees in the Ridgefield National Wildlife Preserve to the east, north, and south of the property and across Lake River to the west of the site. No other documented priority plant species are located within or near the subject site.

HYDROLOGY

Mapped on-site soils are classified as non-hydric by the Natural Resource Conservation Service (NRCS). The majority of the property is covered by impervious surfaces in the form of buildings, pavement, and gravel. Lake River forms the western boundary of the site and is nearly 300 feet wide at this reach. The river is tidally influenced and flows north toward the Columbia River from Vancouver Lake. Two outlets discharge filtered water into Lake River from the steam-based ecological cleanup on-site. Three additional outlets drain stormwater and runoff from on-site into Lake River. The southern and western regions of the property are within the mapped flood plain (Figure 5A).

WETLANDS INVENTORIES

The National Wetlands Inventory (NWI) has classified Lake River as riverine, tidal, unconsolidated bottom, permanent tidal (R1UBV; Figure 4). No wetlands are mapped on-site. A ponded wetland identified as Carty Lake is located north of the subject site in the National Wildlife Refuge and is classified as palustrine, unconsolidated bottom, permanently flooded (PUBH). NWI maps should be used with discretion because they provide general wetland information about a regional area and therefore are limited in accuracy for smaller sites because of their large scale.

The Clark County Wetlands Inventory maps wetland habitat adjacent to the property to the west and north in the same locations as the identified Lake River and Carty Lake Wetland (Figure 5). ELS did not identify riverine wetlands associated with the Lake River habitat along the western shoreline of the project site.

CRITICAL AREAS

The Clark County Sensitive and Habitat Areas map shows the presence of a threatened or endangered species in the northwestern region of the property (Figure 5). Please see Wildlife section for species information. A Riparian Habitat Conservation area shown in the western region of the property and at the northern boundary is associated with Lake River and Carty Lake Wetland.

WILDLIFE

Numerous species of fauna are known to inhabit Lake River and its associated shorelines. A nesting osprey was observed atop the hopper in the central region of the property (Figure 2). Various songbirds, raptors, and waterfowl are common in the area due to the proximity of the high-quality habitat in the Wildlife Refuge. Chinook, Coho, Sockeye, Chum, and Pink Salmon steelhead, sturgeon, and rainbow and cutthroat trout, as well as numerous other less dominant species populate Lake River and Gee Creek. Mink, river otter, opossum, coyote, and raccoons are very common along the shores of Lake River and are likely to be seen at the subject site.

Washington State Priority Species
