Results of this risk assessment indicate that higher trophic mammals such as foxes and deer have hazard quotients less than 0.1 and therefore are not at risk of cPAH toxicity. Avian species have hazard quotients below 1.0, demonstrating that Site conditions do not impact these species. Finally, smaller animals were demonstrated not to have any potential risks associated with cPAHs. Hazard quotients for cPAHs in voles ranged from less than 0.1 to a maximum of 1.2 in Area 26. The assumed cPAH exposure concentration in soil at Area 26 was 37 mg/kg (Appendix I). The results of the ecological risk assessment indicate that cPAH concentrations in individual areas below approximately 30 mg/kg (37 mg/kg/1.2) are protective of ecological receptors at the Site. This level is greater than the acceptable range of human health based cleanup levels established for total cPAHs of 1.0 to 10.0 mg/kg; therefore, cleanup based on human health risk would also be protective of ecological receptors on the Site.

TPH

Bunker C fuels are the primary petroleum constituent on the Site. Limited toxicity data are available for Bunker C in mammalian species. Recognizing that the risk posed by Bunker C is largely attributable to its cPAH components, the risk to ecological receptors from exposure to Bunker C-derived TPH was evaluated based on normalized cPAH concentrations.

The results of the ecological risk assessment indicate that cPAH concentrations in individual areas below approximately 30 mg/kg are protective of ecological receptors at the Site. This level corresponds to a TPH concentration of 76,000 mg/kg based on the regression analysis of the combined Bunker C-impacted areas (Appendix V). This level is greater than the range of cleanup levels established for the Site of 3,100 and 27,000 mg/kg, and therefore cleanup based on human health risk would be protective of ecological receptors on the Site.

Conclusions

Results of the ecological risk assessment indicate that a cPAH concentration of 30 mg/kg would be protective of ecological receptors on the Site. This level corresponds to a TPH concentration of 76,000 mg/kg, much greater than the range of cleanup levels for the Site of 3,100 and 27,000 mg/kg based on human health risk. Therefore cleanup to these levels would also be protective of ecological receptors on Site.

Appendix D – Toxicity Information for Select Constituents

D.1 Monomethyl Amine Nitrate – Monomethylamine

D.1.1 Derivation of Oral Reference Dose

Monomethylamine nitrate (MMAN) was produced by DuPont for use as a sensitizer with water gel explosive formulations. There are no other industrial applications for MMAN. MMAN readily dissociates in water to monomethylamine (MMA) and nitrate, and is not expected to be persistent in the environment. Current analytical methods do not distinguish MMAN from MMA.

EPA has not published toxicity information or toxicity values (e.g., RfD) for MMAN or MMA. MMAN/MMA are not considered carcinogens by EPA. Chronic studies of the toxicological effects of MMA were not found in the current literature. Evidence from occupational studies have shown no long-lasting health effects when workers were exposed to MMAN via inhalation and dermal contact (ACGIH, 1988).

In the absence of human or animal toxicity dose-response studies, the RfD in the draft final RA was derived using an alternative approach. MMA is a natural ingredient in many foods including vegetables (e.g., average concentration in several different types of vegetables was 21.95 ppm) and seafood (Neurath et al., 1977). The RfD was derived based on the amount of MMA an individual consumes daily via ingestion of vegetables. It is assumed that consuming MMA in the diet does not result in any adverse health effects.

The RfD represents the amount of MMA that the average adult and child consumes daily as part of their normal diet (i.e., vegetables only) and then the dose is determined by dividing these values by the child and adult body weights, respectively. These doses are conservative approximations of the average doses of MMA in the diet because (1) the vegetables considered represent a small part of the American diet which contains other sources of MMA (e.g., seafood), (2) the ingestion rate of vegetables used was a U.S. population average which may underestimate the intake of vegetables and MMA by some groups such as vegetarians, and (3) the measurements of MMA in uncooked vegetables are underestimates of the amount consumed because cooking and canning increase MMA content of foods (Lin et al.,1983).

The derived oral RfD is 0.0175 mg/kg-day for a child and 0.0081 mg/kg-day for an adult. The RfD for the adult is lower (i.e., more protective when used in a risk evaluation) than the RfD for the child because the average adult eats less MMA each day per kilogram of body weight. These RfDs are adequate (protective) for evaluating potential risks associated with human exposure to MMAN or MMA. The lower, more protective RfD (i.e., 0.0081) was selected for the Dupont Works Site and approved by Ecology (PIONEER, 1997).

D.2 Toxicity Profile for Arsenic

D.2.1 Introduction

Arsenic is a naturally occurring element that is widely distributed in the earth's crust. In the environment, arsenic is combined with oxygen, chlorine, and sulfur to form inorganic arsenic compounds. It is released into the air by volcanoes, the weathering of arsenic-containing minerals and ores, and by commercial or industrial processes (EPA, 2002a). Arsenic is persistent and does not breakdown in the environment. It can only change its form. Once it is released into the air, it will settle to the ground or be washed out of the air by rain. Once in soil, arsenic can be taken up and converted to organic arsenic by plants and animals.

The primary commercial use of inorganic arsenic is as a wood preservative, while organic arsenic compounds are typically used in pesticides (ATSDR, 2001). At the Site, arsenic is most likely present due to its use as a pesticide to control vegetation along the narrow gauge railroad. Speciation of arsenic at the Site has shown it to be present primarily in the inorganic form.

D.2.2 Health Effects

Inorganic arsenic compounds are generally more toxic to humans than organic arsenic compounds. Breathing high levels of inorganic arsenic can cause a sore throat or irritated lungs. Inhalation of lower levels of arsenic over a long time can cause darkening of the skin and appearance of small "corns" or "warts" on the body (ATSDR, 2001). Inhalation of arsenic has also been associated with development of lung cancer (EPA, 2002a).

Ingestion of high levels of inorganic arsenic can cause death, while ingestion of lower levels can cause nausea, vomiting, anemia, abnormal heart rhythm, and circulatory system damage (ATSDR, 2001). Ingestion of inorganic arsenic has been linked to a form of skin cancer and also to bladder, liver, and lung cancer (EPA, 1994). The World Health Organization, the Department of Health and Human Services, and the EPA have determined that inorganic arsenic is a human carcinogen (ATSDR, 2001).

D.2.3 Basis for Toxicity Values Used in the Risk Assessment

Toxicity values for both cancer and non-cancer health effects were used in the RA to calculate remediation levels. The value used to calculate a remediation level based on non-cancer health effects was an oral reference dose (RfD) of 0.0003 mg/kg-day, based on the observance of hyperpigmentation, ketatosis, and possible vascular complications in people exposed to inorganic arsenic in drinking water. The value used to calculate a cleanup levels and remediation levels based on cancer risk was a cancer potency factor (CPF) of 1.5 $(mg/kg\text{-}day)^{-1}$, based on the occurrence of skin cancer in humans exposed to inorganic arsenic in drinking water (EPA, 2002b).

D.3 Toxicity Profile for Lead

D.3.1 Introduction

Lead is a naturally occurring metal found in small amounts in the earth's crust. Lead is also present due to human activities such as burning fossil fuels, mining, and manufacturing. Manufacturing uses of lead include the production of batteries, ammunition, metal products, and devices used to shield x-rays (ATSDR, 2001).

Lead does not breakdown in the environment. It can only change its form. When lead is released to the air, it may travel long distances before it settles out and sticks to soil particles.

Because of health concerns, the lead content in gasoline, paints, ceramic products, caulking, and pipe solder has been dramatically reduced or eliminated in recent years (ATSDR, 2001).

Human exposure to lead occurs through a combination of inhalation and oral exposure, with the oral route generally contributing a greater proportion of the dose for the general population. The effects associated with exposure to lead are the same regardless of the route of exposure (inhalation and oral) (EPA, 2002).

D.3.2 Health Effects

Lead effects almost every organ and system in the body. The most sensitive system is the central nervous system, particularly in children, where slow cognitive development and delayed growth have been noted following chronic exposure (EPA, 2002). Lead also damages kidneys and the reproductive system. At high levels, lead may decrease reaction time, cause weakness in fingers, wrists, or ankles, and possibly affect memory. Lead may also cause anemia.

Although there is evidence that lead can cause cancer in laboratory animals, there is inadequate evidence to clearly determine that it causes cancer in humans (ATSDR, 2001).

D.3.3 Basis for Toxicity Evaluation in the Risk Assessment

The EPA has chosen to evaluate potential adverse health effects of lead using a physiologically-based model that takes into account lead consumption through diet and environmental sources such as air, soil, and water. The model used for establishing lead remediation levels in non-residential areas like the DuPont Site is the Adult Lead Model (EPA, 1996). This model estimates fetal blood lead concentrations in women exposed to lead in soil. A developing fetus is considered the most sensitive receptor associated with adult exposure to lead. The soil cleanup levels and remediation levels presented in the RA for lead were based on limiting the fetal blood lead level to 10 ug/dl.

D.4 Toxicity Profile for Mercury

D.4.1 Introduction

Mercury is a naturally occurring metal found in the environment. Mercury enters the environment as the result of the normal breakdown of minerals in rocks and soil from exposure to wind and water. Human activities have also resulted in the release of mercury to the environment. Most of the mercury released from human activities comes from the burning of fossil fuels, mining, smelting, and from solid waste incineration (ATSDR, 1999). Mercury can exist in three general forms: as metallic mercury, inorganic mercury, and organic mercury.

Mercury is persistent and does not breakdown in the environment. Once it is released into the air, mercury will settle to the ground or be washed out of the air by rain. Once in soil, mercury combines with other elements, such as chlorine, sulfur, or oxygen, to form inorganic mercury compounds or "salts". Alternatively, mercury deposited on the soil may be taken up by microorganisms and converted to organic mercury (ATSDR, 1999). Metallic mercury is not typically found in the environment.

Exposure to organic mercury is generally only of concern when consumption of fish and other aquatic organisms is considered likely, due to the ability of methyl mercury to concentrate in animal tissues. At the DuPont Site, potential exposure to mercury is through direct contact with soil. Therefore, the focus of this toxicity profile is on the health effects associated with inorganic mercury.

D.4.2 Health Effects

In general, exposure to inorganic mercury is less harmful than exposure to the other forms of mercury because inorganic mercury is less able to reach the brain. Inhalation of inorganic mercury is not associated with adverse health effects. However, ingestion of high levels of inorganic mercury can permanently damage the brain, kidneys, and developing fetuses. Effects on brain functioning may result in irritability, shyness, tremors, changes in vision or hearing, and memory loss (ATSDR, 2001).

Although there is evidence that inorganic mercury can cause cancer in laboratory animals, there is inadequate evidence to clearly determine that it causes cancer in humans (ATSDR, 2001).

D.4.3 Basis for Toxicity Value Used in the Risk Assessment

The toxicity value used to calculate cleanup and remediation levels based on non-cancer health effects was an oral reference dose (RfD) of 0.0003 mg/kg-day. This value was calculated from a study showing immune system effects in rats fed inorganic mercury in their diet (EPA, 2002).

D.5 Toxicity Profile for 2,4,6-Trinitrotoluene (TNT)

D.5.1 Introduction

2,3,6-Trinitrotoluene (TNT) is a yellow, odorless solid that does not occur naturally in the environment. It is an explosive used in military shells, bombs, grenades, for industrial uses, and in underwater blasting. TNT enters the environment resulting from manufacturing activities, processing and destruction of bombs, and the recycling of explosives (ATSDR, 2001). Once in the environment, it is rapidly broken down by sunlight. It can also be broken down by microorganisms, but this is a much slower process. TNT can accumulate in small amounts in fish and plants, but potential exposure to humans at the DuPont Site is through accidental ingestion of soil.

D.5.2 Health Effects

Workers who were exposed to high airborne levels of TNT during production of explosives experienced health effects such as anemia and abnormal liver function. Other effects seen in humans include skin irritation after prolonged skin contact, and cataract development after more than one year of exposure (ATSDR, 2001).

Although there is evidence that TNT can cause cancer in laboratory animals, there is inadequate evidence to clearly determine that it causes cancer in humans (ATSDR, 2001).

D.5.3 D.5.3 Basis for Toxicity Values Used in the Risk Assessment

Toxicity values for both cancer and non-cancer health effects were used in the RA to calculate remediation levels. The value used to calculate cleanup levels and remediation levels based on non-cancer health effects was an oral reference dose (RfD) of 0.0005 mg/kg-day, based on the observance of liver effects in dogs exposed to TNT in their diet. The value used to calculate a remediation level based on cancer risk was a cancer potency factor (CPF) of 0.03 $(mg/kg\text{-}day)^{-1}$, based on the occurrence of bladder tumors in rats exposed to TNT in their diet (EPA, 2002).

D.6 Toxicity Profile for Total Petroleum Hydrocarbons (TPH)–as Bunker C Fuel

D.6.1 Introduction

Total petroleum hydrocarbons (TPH) is a term used to describe a large family of several hundred chemical compounds that originally come from crude oil. Crude oil is used to make petroleum products. These products contain so many individual compounds that it is not practical to quantify each one. Instead, identification is made by performing chemical analysis of a category of TPH, as defined by weight of product. Some compounds that may be found in TPH are hexane, jet fuels, mineral oils, benzene, toluene, xylenes, naphthalene, and fluorine, as well as other petroleum products and gasoline components. However, it is likely that any given sample of TPH will only contain a subset of these compounds (ATSDR, 2001).

TPH may enter the environment through accidental spills, from industrial releases, or as byproducts from commercial or private uses. Once in the environment, certain fractions of TPH may be broken down by microorganisms, while other fractions may move into soil where they may persist for a long time (ATSDR, 2001).

The TPH product used at the DuPont Site was Bunker C fuel. Therefore, the discussion of health effects will pertain to those associated with exposure to this TPH product.

D.6.2 Health Effects

Human contact with Bunker C fuel has been associated with skin irritation. In addition, ingestion can cause nausea, vomiting, diarrhea, and central nervous system effects such as restlessness (U.S. Oil & Refining Co., 1998).

Bunker C Fuel may also contain some polycyclic aromatic hydrocarbons (PAHs), that have been shown to cause skin cancer in laboratory animals, however, there is inadequate evidence to clearly determine that they cause cancer in humans.

D.6.3 Derivation of a Bunker C Cleanup Level

Recognizing that the risk posed by Bunker C is largely attributable to its carcinogenic polycyclic aromatic hydrocarbon (cPAH) components, a Site-specific correlation analyses were performed to assess the statistical relationship between cPAH and TPH concentrations. Thus the Bunker C cleanup level is based on the cPAH toxicity values. See Appendix C for details on how this information was used to derive the cleanup level.

Appendix E – Soil Cleanup Level and Remediation Level Calculations

E.1 Introduction

This appendix presents the calculations that were performed to develop the cleanup levels and remediation levels presented in Chapter 3. The equations used to calculate soil cleanup and remediation levels were obtained from the WAC 173-340-745. The EPA has chosen to evaluate the potential health effects of lead using a physiologically based model and the model equations and inputs are discussed in Chapter 3 of the RA.

The equations, inputs, and resulting cleanup or remediation levels are presented in the following tables:

- Table E-1 – Commercial Land Use Soil Remediation Levels.
- Table E-2 – Golf Course Land Use Soil Remediation Levels.
- Table E-3 – Historical Land Use Soil Remediation Levels.
- Table E-4 – Industrial Land Use Soil Cleanup Levels.
- Table E-5 – Open Space Land Use Soil Remediation Levels.

Appendix F – Summary Statistics and Comparison to Standards

F.1 Introduction

This Appendix presents the summary statistics that were calculated for each EU as well as the comparison between of the resulting exposure point concentrations and the cleanup levels and remediation levels which are described in Chapter 3.

F.2 Summary Statistics For Each Evaluation Unit

The summary statistics for each EU are presented in Tables F-1 through F-48 as follows:

Table F-1 – Commercial Evaluation Unit 1 (0 to <=1 foot)
Table F-2 – Commercial Evaluation Unit 1 (>1 to <=15 feet)
Table F-3 – Commercial Evaluation Unit 2 (0 to <=1 foot)
Table F-4 – Commercial Evaluation Unit 2 (>1 to <=15 feet)
Table F-5 – Commercial Evaluation Unit 3 (0 to <=1 foot)
Table F-6 – Commercial Evaluation Unit 3 (>1 to <=15 feet)
Table F-7 – Commercial Evaluation Unit 4 (0 to <=1 foot)
Table F-8 – Commercial Evaluation Unit 4 (>1 to <=15 feet)
Table F-9 – Commercial Evaluation Unit 5 (0 to <=1 foot)
Table F-10 – Commercial Evaluation Unit 5 (>1 to <=15 feet)
Table F-11 – Commercial Evaluation Unit 6 (0 to <=1 foot)
Table F-12 – Commercial Evaluation Unit 6 (>1 to <=15 feet)

Table F-48 – Open Space Evaluation Unit 4 (>1 to <=15 feet)

F.3 Statistical Formulas Used To Calculate the Summary Statistics

This section presents the statistical formulas that were used to calculate the summary statistics presented in Tables F-1 through F-48.

F.3.1 Geometric Mean

Returns the mean value of the natural logarithm transformed values. The geometric mean is calculated as follows:

$$\hat{m} = e\left(\bar{y} + \frac{s_y^2}{2} \right)$$

F.3.2 Logarithmic Upper Confidence Limit for the Mean

Returns the one-sided natural logarithm upper confidence limit on the mean. The upper confidence limit on the lognormal mean is calculated as follows:

$$UL_{1-a} = e\left(\bar{y} + 0.5 s_y^2 + \frac{s_y H_{1-a}}{\sqrt{n-1}} \right)$$

Values of the H statistic not found in the lookup table were calculated using 4-Point Lagrangian Interpolation. Lagrangian interpolation is calculated as follows:

$$y_i = \sum_{i=0}^{n} \frac{II_n(X)}{(X - X_{i)} II'(X_i)} y_i, \quad i = 0,1,\cdots n,$$

$$II(x) = (X - X_o)(X - X_1)\cdots(X - X_n)$$

$$II'(X) = \frac{d}{d_x} II_n(X)$$

F.3.3 Mean (arithmetic)

Returns the arithmetic mean of the values. The mean is calculated as follows:

$$\overline{X} = \sum \frac{X_i}{n}$$

F.3.4 Median

Returns the median value of the distribution. The median is the value that divides a distribution exactly in half. The median is also referred to as the 50th percentile. The median is calculated as follows:

1. Order data from lowest to highest to obtain sample order statistics.

   $X_{[1]} \le X_{[2]} \le \cdots \le X_{[n]}$

2. If n is odd the sample median is the $\frac{(n+1)}{2} th$ value.
3. If n is even the sample median is the average of the $\frac{n}{2} th$ and the $\frac{(n+2)}{2} th$ values.

F.3.5 Maximum Detected Value

Returns the maximum detected value in the distribution.

F.3.6 Maximum Non-Detected Value

Returns the maximum non-detected value in the distribution.

F.3.7 Minimum Detected Value

Returns the minimum detected value in the distribution.

F.3.8 Minimum Non-Detected Value

Returns the minimum non-detected value in the distribution.

F.3.9 Mode

Returns the most frequently occurring score in the distribution.

F.3.10 Sample Standard Deviation

The standard deviation returns the deviation of the sample distribution. The sample standard deviation is calculated as follows:

$$s = \sqrt{\frac{SS}{n-1}}$$

Where,

s	=	Sample standard deviation
SS	=	Sum of Squared deviations
n	=	Number of scores in the sample

The sum of squared deviations is calculated using the following formula:

$$SS = \sum X_i^{\,2} - \frac{(\sum X_i)^2}{N}$$

F.3.11 Upper Confidence Limit for the Mean

Returns the one-sided upper confidence limit on the mean using the following formula. The t-statistic is used to estimate the location of the mean in a sample distribution when the population standard deviation (s) and the population mean (μ) are unknown. The t-statistic is calculated as follows:

$$\mu = \overline{X} \pm t s_{\overline{x}}$$

The standard error of a distribution of sample means is calculated as follows.

$$s_{\overline{X}} = \frac{s}{\sqrt{n}}$$

How well the sample standard deviation (s) estimates the population standard deviation depends mainly on sample size, which is described in terms of degrees of freedom. The degrees of freedom describes the number of scores in a sample that are free to vary. The degrees of freedom is calculated as follows.

$$df = n - 1$$

F.3.12 Distribution Tests

Shapiro and Wilk Test (W Test)

The W statistic tests the null hypothesis (H_0) that the data have been drawn from a normal distribution. The alternative (H_1) is that the underlying population is not normally distributed. This test is applicable when the sample size is ≤ 50. The W statistic is calculated as follows:

1. Compute the denominator of the W test statistic

$$d = \sum_{i=1}^{n} (X_i - \overline{X})^2$$

2. Order data from lowest to highest to obtain sample order statistics.

$$X_{[1]} \le X_{[2]} \le \cdots \le X_{[n]}$$

Where,

$X_{[1]}$	=	Lowest score

$X_{[n]}$ = Highest score

3. Compute K.

   $K = \frac{n}{2}$ if n is even

   $K = \frac{n-1}{2}$ if n is odd

4. Get coefficients for a_i from a lookup table based on the K value.

5. Compute W statistic

$$W = \frac{1}{d}\left[\sum_{i=1}^{K} a_i\left(X_{[n-i+1]} - X_{[i]}\right)\right]^2$$

6. Reject H_o at the α significance level (an α of 0.05 was used) if W is less than the quantile provided in the lookup table.

Note: To test the Null Hypothesis

H_o: The population has a lognormal distribution

versus

H_1: The population does not have a lognormal distribution

The W Test can also be used to test the null hypothesis (H_o) that the data have been drawn from a lognormal distribution by using $Y_i = \ln X_i$ in place of X_i in the calculations.

D'Agostino's Test

The D statistic is a compliment to the W Test in that it also tests the null hypothesis of normality or lognormality. However the D statistic is applicable to sample sizes between 50 and 1,000. The D statistic is calculated as follows:

1. Order data from lowest to highest to obtain sample order statistics.

$$X_{[1]} \le X_{[2]} \le \cdots \le X_{[n]}$$

Where,

$X_{[1]}$ = Lowest score

$X_{[n]}$ = Highest score

2. Compute the D statistic.

$$D = \frac{\sum_{i=1}^{n}\left[i - \frac{1}{2}(n+1)\right]X_{[i]}}{n^2 S}$$

Where,

$$S = \left[\frac{1}{n} \sum_{i=1}^{n} \left(X_i - \overline{X} \right)^2 \right]^{\frac{1}{2}}$$

3. Transform D to the Y statistic by performing the following computation.

$$Y = \frac{D - 0.28209479}{0.02998598 \div \sqrt{n}}$$

4. Reject at the α significance level (an α of 0.05 was used) the null hypothesis that the data were drawn from a normal distribution if Y is less than $\frac{\alpha}{2}$ quantile or greater than the $1 - \frac{\alpha}{2}$ quantile distribution of Y. The quantiles are obtained from a lookup table.

Values of quantities of the y statistic not found in the lookup table are calculated using linear interpolation. Linear interpolation is performed as follows:

$$fp = (1 - p) f_o + p f_1,$$

$$p = \frac{(X - X_o)}{(X_1 - X_o)}$$

Note: The Y statistic can also be used to test the null hypothesis of a lognormal population by using $Y_i = \ln X_i$ in place of X_i in the calculations.

F.4 Comparison to Standards

The MTCA RME concentrations that are presented in Tables F-1 through F-48 were compared to land use specific cleanup levels and remediation levels. Only constituents of concern that were evaluated in Chapter 4 of the RA were compared to the cleanup levels and remediation levels. Tables F-49 through F-53 present the EU and constituent-specific evaluation of the MTCA RME concentrations to the cleanup levels and remediation levels as well as an evaluation of the MTCA three-fold criteria. The tables are organized as follows:

- Table F-49 – Comparison of Commercial EUs to Soil Cleanup Levels and Remediation Levels
- Table F-50 – Comparison of Golf Course EUs to Soil Cleanup Levels and Remediation Levels
- Table F-51 – Comparison of Historical EUs to Soil Cleanup Levels and Remediation Levels
- Table F-52 – Comparison of Industrial EU to Soil Cleanup Levels and Remediation Levels
- Table F-53 – Comparison of Open Space EUs to Soil Cleanup Levels and Remediation Levels

TABLE OF CONTENTS

SECTION 1 – INTRODUCTION AND GENERAL INFORMATION 1-1

1.1 Introduction 1-1
1.2 Goals of the Cleanup Action 1-1
1.3 Specific Cleanup or Performance Requirements 1-1
1.4 Owners and Operators 1-1
1.5 Site Characterization Information 1-2
1.6 Schedule 1-3
1.7 Basis for Plan of Action 1-3
1.8 General Process - Large Scale, Small Scale, and Groundwater Actions 1-3
1.8.1 General Process – Large Scale Applications 1-4
1.8.2 General Process – Small Scale Applications 1-4
1.8.3 No Action 1-4
1.8.4 General Process – Groundwater 1-5
1.8.5 Cleanup Units 1-5
1.8.6 Facilities 1-5
1.9 Permits and Approvals 1-6
1.10 Health and Safety 1-6

SECTION 2 – GENERAL DESIGN SPECIFICATIONS 2-1

2.1 Engineering Design 2-1
2.1.1 Engineering Design and Performance Criteria 2-1
2.1.1.1 Threshold Criteria 2-1
2.1.1.2 Performance Criteria and Goals - Cap Construction 2-1
2.1.2 Engineering Justification for Design and Operation Parameters 2-1
2.1.3 Management and Disposal of Residual Contamination 2-2
2.2 Environmental Controls 2-2
2.2.1 Control of Hazardous Materials Spills and Accidental Discharges 2-2
2.2.2 Air Pollution Controls 2-2
2.2.3 Water Pollution Controls 2-3
2.2.4 Erosion Control 2-3
2.2.5 Slope Stability Concerns 2-3
2.2.6 Re-contamination Controls 2-4
2.2.7 Dust Suppression Controls 2-4
2.2.8 Decontamination of Equipment 2-4
2.2.9 Solid Waste 2-4
2.3 Facility Specific Characteristics 2-4
2.3.1 Operating Facilities 2-4
2.3.2 Force Majure 2-4
2.3.3 Local Planning and Development Issues or SEPA Information not in RI/RA/FS 2-5
2.3.4 Permits and Approvals 2-5
2.3.5 Institutional Controls 2-5
2.4 Construction Documentation 2-5
2.4.1 As-Builts 2-5
2.4.2 Survey Steps 2-6
2.4.3 Documentation and Record Keeping 2-6

SECTION 3 – HEALTH AND SAFETY 3-1

3.1 Health and Safety Plan 3-1
3.1.1 General Policies 3-1
3.1.2 Responsibility 3-2
3.1.2.1 Project Direction 3-2
3.1.2.2 Project Manager/Site Supervisor 3-3
3.1.2.3 Contractor Health and Safety Managers 3-3
3.1.2.4 Project Personnel 3-4
3.1.3 Site Access 3-4
3.1.3.1 Access Restrictions 3-4
3.1.3.2 Site Access Procedures 3-5
3.1.4 Health and Safety Training 3-5
3.1.5 Communication 3-5
3.2 General Cleanliness 3-6
3.2.1 Clean, Orderly, and Hazard-Free Work Site 3-6
3.2.2 Decontamination of Personnel 3-6

SECTION 1 – INTRODUCTION AND GENERAL INFORMATION

1.1 Introduction

The purpose of this Remedial Design Report (RDR) is to provide design criteria and information, engineering concepts, and construction plans and specifications for the cleanup actions at the former DuPont Works Site (Site). A Consent Decree between the lead agency, Washington State Department of Ecology (Ecology), and the principal responsible parties, the Weyerhaeuser Company (Weyerhaeuser) and E.I. duPont de Nemours and Company, Inc. (DuPont) to enact these actions was entered into effective August 14, 2003. The RDR was developed in accordance with the Model Toxics Control Act Cleanup Regulation (MTCA).

1.2 Goals of the Cleanup Action

The goals of cleanup actions at the Site are to complete the work necessary to protect human health and the environment (WAC 173-340-350). In particular this means: Achieve cleanup standards that will be protective of human health and the environment; and comply with chemical-, location-, and action-specific applicable, relevant, and appropriate requirements (ARARs).

1.3 Specific Cleanup or Performance Requirements

Because of the complexity of the Site, a Site-specific risk assessment (RA) using land use specific exposure scenarios was used to develop Site-specific cleanup levels (CLs) and remediation levels (RLs) protective of human health and the environment (WAC 173-340-700 (3)(c)). These levels are listed in Table 1-1.

1.4 Owners and Operators

Weyerhaeuser is the current owner of the Site. DuPont owned the property between 1906 and 1974, and was the operator of the former DuPont Works Facility. All work described in this document will be conducted under the supervision of both Weyerhaeuser and DuPont (the Companies). West Shore Corporation will perform the day-to-day project management tasks. Active Construction is the Remediation Contractor. A contractor will be selected in late 2003 to build the golf course (GC). Asmundson and Company (A&C) is the GC Designer.

Various other consultants and contractors will be used, as needed, to complete specific tasks. Operations and maintenance (O&M) tasks following construction will also be completed by contractors of the Companies until the GC can be sold or donated to a third party. The names and qualifications of these contractors have not been finalized.

1.5 Site Characterization Information

The Site is located in DuPont, Washington, as shown in Drawing PTC-1. Site contamination is present in soils, debris and groundwater. Of the 213 constituents evaluated during Site characterization, 11 in soil (aldrin, arsenic, benzo(a)pyrene, dinitrotoluene (DNT), copper, lead, mercury, nitrobenzene, 2,4,6-trinitrotoluene (TNT), tetrachlorethene, and total petroleum hydrocarbon (TPH)) and one in groundwater (only DNT) were identified for remedy. The contamination is a result of manufacturing at, and decommissioning of the former explosives manufacturing facility. While the contamination is Site-wide, the highest concentrations occur in areas associated with former building foundations, in areas where manufacturing materials were disposed, and along the Narrow Gauge Railroad (NGRR) tracks. Drawing PTC-2 identifies the areas where interim source removal actions have occurred, and require no further action. Drawing PTC-3 presents the future land use areas for the Site.

Site soil contamination occurs as two distinct categories: lead and arsenic impacted surface soils, and isolated small occurrences of TPH, mercury, DNT and TNT, nitrobenzene, benzo(a)pyrene, and/or arsenic/lead impacted subsurface (i.e., depth greater than one foot below ground surface [BGS]) soils. The first group, referred to as Large Scale Remediation Units, is identified in Drawing PTC-4. The second group, referred to as Miscellaneous Small Remediation Units (MSUs) throughout this RDR, represents less than one percent of the total volume of contaminated soils, and is identified in Drawings PTC-5 through PTC-8. The total volume of contaminated soil is approximately 905,000 cubic yards (CY). The industrial area north of Sequalitchew Creek is in compliance with industrial cleanup standards with the exception of two MSUs.

NGRR MSUs are located within Sequalitchew Creek Canyon, an environmentally-sensitive area (see Drawing PTC-6). The NGRR track bed has elevated arsenic and lead concentrations. The estimated volume of contaminated soil along the Sequalitchew Creek NGRR is 7,800 CY. In addition, there are former NGRR track beds south of Sequalitchew Creek that will be

remediated. The total volume of contaminated soil associated with NGRR track beds is approximately 34,606 CY (these locations are also shown in Drawing PTC-6).

Contaminated debris is also categorized as a MSU (see Drawing PTC-8). It occurs as piping, brick and other construction materials painted with lead-based paint. The majority of this debris is buried making volume calculations uncertain. The volume of contaminated debris is estimated to be 33,400 CY.

Stockpiles of formerly-excavated material are also categorized as a MSU (see Drawing PTC-8). Stockpiles primarily consist of soil, although in some cases there is also demolition debris. The volume of stockpile contaminated debris is estimated to be 1,000 CY.

DNT is the only chemical that is of potential concern in groundwater. All other chemicals are either below levels of concern, were not detected, or are below background concentrations. Data from 34 rounds of sampling at 30 well locations indicate that low DNT concentrations have been consistently detected in five of 30 Site groundwater monitoring locations.

1.6 Schedule

Table 1-2 presents the project schedule as it is known at the time of this document. It is highly dependant upon regulatory issues and the final volume of soil requiring remediation.

1.7 Basis for Plan of Action

The cleanup action decision is based on the Remedial Investigation (RI), Risk Assessment (RA) and Feasibility Study (FS) completed by Weyerhaeuser and DuPont, and other relevant documents in the administrative record including the Cleanup Action Plan (CAP) issued by Ecology. These reports document current and former Site conditions and considerations as well as the selected remedial alternatives for the different remediation units (RU).

Actions undertaken at the Site will be done under a consent decree agreed to by the Companies and Ecology and filed with the Pierce County Superior Court on August 14, 2003. This consent decree requires that the Companies undertake the remedial actions identified in the CAP.

In accordance with MTCA, the purpose of this action is to protect human health and the environment. Human health and ecological evaluations have been performed for the Site. Ingestion of contaminated soil by future on-Site workers and ingestion of soil, plants, or soil biota by ecological receptors are the primary pathways of concern. By removing the contaminated soils from the Site or covering them with a cap/cover system, these pathways are eliminated. Institutional controls will prevent disruption to the cap/cover and thereby prevent exposure to contaminated soils.

1.8 General Process - Large Scale, Small Scale, and Groundwater Actions

Remediation of the Site will be completed by two different groups of methods:

- Those for large scale applications (lead and arsenic soils).
- Those for small scale applications (MSUs).

No active remediation other than long-term monitoring of groundwater will occur. These methods/decisions are discussed in the following sections.

1.8.1 General Process – Large Scale Applications

In general, this alternative involves the mass excavation of the top one-foot of soil in targeted areas of the Site, followed by the transfer of the excavated soil, and the consolidation of these soils in selected locations on-Site. Additional excavation will be required for soil greater than one foot below current ground surface if either confirmational or RI testing shows that they contain contaminant concentrations greater than RLs. If the confirmation results are greater than the GC placement area (PA) RLs, then the soil will be disposed of off-Site. Each of these consolidation locations (also called placement areas or PAs) will be capped and lie beneath the planned GC.

1.8.2 General Process – Small Scale Applications

Four remediation methods will be used for small-scale applications. They are:

- **Off-Site Disposal at a Landfill –** For this application, soils above Site-specific CLs or RLs for non-lead and non-arsenic contaminated soils will be excavated and transported for disposal at an off-Site disposal facility. Additional excavation will be required if either confirmational or RI testing shows that soil beyond the initially excavated area contains contaminant concentrations greater than CLs or RLs. These excavated soils will also be stockpiled, sampled for designation, and transported to an approved off-Site disposal facility.

- **Cap/Cover –** This alternative involves the installation of an engineered cap/cover 18 inches (?) in thickness over the contaminated soil. This cap will be placed on the GC and, if applicable, historical land use areas with in-situ contaminant concentrations less than the applicable RL but greater than the Site-specific commercial CL.

- **On-Site Deposition with Cap/Cover** – This alternative will involve the excavation of the existing soils containing contaminant concentrations above the CL but below the RL for a particular area, followed by the transfer, consolidation and capping of the excavated soils beneath the planned GC. If the confirmation sample results exceed the GC PA RLs, then the soil will be disposed of off-Site. This alternative will be used for lead and arsenic impacted soils only.

- **Capping** – A gravel and asphalt cap will be used along the Sequalitchew Creek NGRR to cap existing soils containing lead concentrations above the CL (118 mg/kg) but below the RL for a particular area. This asphalt and sub-base cap will act as the human health and ecological exposure barrier. No excavation of underlying soils will occur outside the Sequalitchew Creek NGRR except down slope of LR-68. This is an area where debris was dumped and is the only place where excavation will occur other than the actual track bed. Efforts will be made to minimize logging down slope during this excavation.

1.8.3 No Action

No action is appropriate in areas that are highly ecologically sensitive. These areas, the Sequalitchew Creek Canyon (excluding railroad track beds, and down slope of LR-68), and the open space setbacks surrounding Old Fort Lake, require special consideration to the impacts required to cleanup existing contamination (largely low concentrations) vs. impacts to the local

ecology if no action were taken. This net environmental benefit evaluation indicates that no action is a positive approach for these areas.

No action is also appropriate for small isolated occurrences of cadmium; an element that was not used or generated as part of the manufacturing activities or decommissioning of the buildings at the Site. No action is appropriate since the following conditions have been met:

- Cadmium has not been detected in groundwater;
- Cadmium concentrations are low (near the CL);
- The average/mean cadmium concentration is below the CL;
- The number of exceedances (less than five percent) of the cadmium CL are low in comparison to the number of detections and/or samples collected; and
- No known sources of cadmium are associated with activities at the Site.

1.8.4 General Process – Groundwater

DNT has been detected in groundwater below the Site at concentrations above drinking water standards but consistently below the MTCA Method B value. Because the majority of detected DNT concentrations are consistently low, are not affecting the regional aquifer, are not affecting surface water, and the aquifer is not used as a drinking water source, Natural Restoration has been selected as the remedy. Ecology agreed to the selection of this alternative by issuing a "No Active Remedial Action" letter for Site groundwater (Ecology 1996).

Groundwater monitoring will be required at the Site until DNT concentrations below drinking water standards are obtained in four consecutive sampling rounds. Monitoring at individual wells will discontinue based on approval from Ecology. The wells that will be monitored as part of the cleanup action are monitoring wells MW-3, MW-6, MW-19, and MW-22 and a new monitoring well installed down gradient of RI Area 25. Seep 1 will be sampled during annual groundwater monitoring events after the surface soil mass excavation remediation work has been completed. Ecology may also require groundwater monitoring at other locations.

1.8.5 Cleanup Units

The Site has been divided into seven different cleanup units based on several factors including: location, haul distances, excavation, placement logistics, staging, and GC construction considerations. These areas have been designated as Cleanup Units (CUs). Drawing SHEET 3 identifies each of the CUs. The intention is to complete the remediation of one CU before moving on to the next unit. The groundwater CU is considered separately from the seven soil CUs.

1.8.6 Facilities

The Site has no operating facilities. The only structures on Site are temporary office trailers and three well houses. The well houses will be removed as part of the remediation process. The maintenance buildings, clubhouse and other GC support structures will be completed concurrently with the GC construction but not as part of the remediation. The design of these

structures is outside the scope of this RDR, but the conceptual support facility plan is presented in drawing SHEET 2.

1.9 Permits and Approvals

MTCA includes an exemption from local government permits and approval processes for remedial actions performed under a consent decree, order, or agreed order (RCW 70.105D.090). State and local permits are not required for actions undertaken in association with MTCA, but Ecology must ensure that the substantive requirements of any permit that will normally be required for any activities occurring during the cleanup are met.

However, Ecology determined that the remedial action may result in probable significant adverse impacts to several elements of the environment and, therefore, determined that an Environmental Impact Statement (EIS) was required. An EIS for the cleanup action was completed in 2000 (Ecology, 2000). Sections 2.3.3 and 2.3.4 present more specific information concerning permit issues.

1.10 Health and Safety

All work conducted during this remedial action will comply with Washington State Industrial Safety and Health Administration (WISHA) regulations and requirements and policies of the Companies. A project specific Health and Safety Plan (HASP) has been developed and is part of the Hazards Communication Program.

Table 1-1 – Soil and Groundwater Cleanup, Screening, and Remediation Levels for each Land Use

Chemical	Commercial and Golf Course Cleanup and Remediation Levels (mg/kg)	Golf Course Cap Remediation Levels (mg/kg)	Historical and Open Space Cleanup and Remediation Levels (mg/kg)	Industrial Cleanup and Remediation Levels (mg/kg)	Groundwater Screening Concentration (ug/L)

SECTION 2 – GENERAL DESIGN SPECIFICATIONS

2.1 Engineering Design

2.1.1 Engineering Design and Performance Criteria

Certain criteria were assumed and/or established during the design process. They fall into two categories; threshold criteria and performance criteria or goals. These criteria are discussed in the following sections.

2.1.1.1 Threshold Criteria

The threshold criterion chosen for the design was to provide remedial alternatives that protect human health and the environment (WAC 173-340-350). In particular, this means the proposed Remedial Action Objectives (RAO) for the Site are designed to:

- Achieve cleanup standards that will be protective of human health and the environment; and

- Comply with chemical-, location-, and action-specific ARARs.

2.1.1.2 Performance Criteria and Goals - Cap Construction

The engineered cap/cover will be designed and constructed so that it acts as a protective barrier against direct contact with humans or animals. At a minimum the cap/cover will include:

- Ecological Barrier: This will consist of a minimum of 12 inches of gravel. This decision is based upon the determination of Ecology's Ecological Risk Specialist that there is low likelihood that soil biota will travel through this depth of gravel to get to underlying soils. On-Site observations show that Steilacoom gravels do not support biological growth or activity. In lieu of gravels, a geo-textile that meets the same performance standards can be used. The specific liner to be used has not been selected. Field requirements will determine the need and specification of the liner.

- Human Health Barrier: This barrier will consist of the soil necessary to make the cap/cover a minimum of 18 inches thick. If gravel is used for an ecological barrier, the depth of soil cover will be no less than six inches. If geo-textile is used, the soil will be a minimum of 18 inches thick. This decision is based upon the maximum depth in which a GC worker is expected to excavate to make repairs to waterlines and irrigation piping.

- Vegetated Areas: Additional soil may be required above the ecological and human health cap/cover in areas where vegetation will be planted. At a minimum, this soil will be thick enough to accommodate the root ball of any planted vegetation.

2.1.2 Engineering Justification for Design and Operation Parameters

The engineering design criteria are intended to ensure that the threshold criteria and cap construction performance goals are met. The GC and associated PAs are designed to meet the following engineering criteria:

- Ensure adequate capacity for placement of all impacted Site soils for which the on-Site deposition and Cap/Cover alternative was selected (i.e., approximately 1,900,000 CY).
- Ensure that all potential runoff and irrigation water from the GC remain in the GC footprint.
- Locate lateral irrigation lines within the CAP in the placement areas.
- Where possible, avoid putting irrigation and drainage lines in PAs.
- Backfill irrigation trenches with clean material.
- Locate PAs to minimize haul distances.
- Create an ecological barrier consisting of at least 12 inches of gravel.
- Create a human health barrier consisting of at least six inches of soil.
- Ensure vegetated areas above placement areas will have at least four inches of clean soil below the root ball of shrubs.

2.1.3 Management and Disposal of Residual Contamination

Residual contamination will be controlled by installation of the cap/cover described in section 2.1.1.2. The installation of the cap/cover will meet the RAOs by preventing direct contact exposure with soil above the cleanup standards. This combination will act as an exposure barrier to both ecological receptors and humans.

2.2 Environmental Controls

This section identifies the actions to be taken to mitigate or avoid causing adverse environmental impacts related to: air quality, water quality, soil erosion, hazardous liquid and solid waste caused by construction activities. The remedial activities are to be performed in compliance with all applicable laws and regulations and in accordance with the requirements of the Companies and Ecology.

2.2.1 Control of Hazardous Materials Spills and Accidental Discharges

Liquid storage or treatment is not part of the remediation process and therefore, containment structures and leak detection devices are not of concern. An accidental spill response cleanup and notification plan has been developed and the procedures will be understood and used by all applicable employees. In general, all equipment will be re-fueled in the equipment storage and staging area.

2.2.2 Air Pollution Controls

The following steps will be taken to minimize wind blown dust:

1. Loads of materials, debris and waste materials will be covered if taken from the Site.
2. Water will be applied at all construction site areas and haul routes to control visible dust.

3. Vehicle speeds will not exceed posted limits.

The Site Air Monitoring Plan has been developed and is presented in Appendix A.

2.2.3 Water Pollution Controls

Runoff waters will be minimized and contained. No pollutants such as chemicals, fuels, lubricants, or other harmful wastes will be allowed into or alongside streams and impoundments or into channels leading thereto or onto the ground. Lubricating oils, hydraulic fluids, greases, and other such products will be handled carefully to minimize any potential for release. An accidental spill response cleanup and notification plan has been developed and the procedures will be understood and used by all applicable employees.

2.2.4 Erosion Control

Due to high infiltration rates and past experience, erosion will be a minor concern during the remediation of the Site. In areas where remediation activities could impact surface water bodies (i.e. within 200 feet of Sequalitchew Creek and Old Fort Lake), active erosion and sediment control procedures will be used. These methods and procedures include the minimum requirements for storm water control outlined in Ecology's storm water manual. Temporary erosion controls for the Sequalitchew Creek NGRR remediation will consist of continuous, silt fencing along the top of the slope on the creek side, and sediment ponds formed with hay bales at approximately 50-foot spacing along the wet areas in the track bed. Rip rap at outfalls of existing culvert pipes where scouring may occur, might also be required. Along the potentially impacted areas of Old Fort Lake, the primary method to be used will be silt fences and gravel filters. Other measures that may be used, based upon need, include sediment ponds and vegetated interceptor swales as warranted by water velocities and site slopes. The following will also be included, if necessary:

- Exposed slopes will be covered, and if necessary construction runoff (e.g., concrete wastes, equipment oils) will be collected.

- Sediment ponds will be used to retain/infiltrate runoff during construction, allowing for clean-out of ponds to finish grade elevation after Site stabilization.

- Accidental spill response cleanup and notification procedures will be available if needed.

- Wet Ponds will be used to provide dead storage for particulate/contaminant settling prior to discharge to infiltration systems constructed in conjunction with the GC.

2.2.5 Slope Stability Concerns

Slope stability is a potential concern associated with NGRR remediation work in Sequaltichew Creek Canyon. All of the work in the Sequalitchew Creek Canyon NGRR will occur on the railroad bed, and down slope of LR-68. This is the only place where excavation will occur, other than the actual track bed. Efforts will be made to minimize logging down slope during this excavation. In addition, erosion controls will be implemented to minimize the potential impact of erosion, which could decrease slope stability.

2.2.6 Re-contamination Controls

It will be unacceptable to track, spill or dump contaminated soils on remediated areas. Once the excavation takes place, an area will be assumed to be clean, and heavy equipment and trucks will stay out of the area if they are working in adjacent areas that have yet to be remediated. Confirmation sample results will then be collected to document that the resulting concentrations are below the Site-specific RLs. Once this step is complete, the goal is to avoid re-contaminating an area by moving equipment from contaminated areas into the areas that already have been remediated. The overall strategy for remediating each CU, individually, will also facilitate avoiding cross-contamination by staging the excavation in a manner that all on-going work is performed in areas that are yet to be excavated. Haul routes will be planned and constructed to eliminate, as best as possible, the use of remediated areas. If a remediated area must be used as a haul route an additional three inches of soil will be excavated and placed in a PA following its use, and the underlying soils retested for compliance.

2.2.7 Dust Suppression Controls

Visible dust will be suppressed with water. Water trucks will apply water to all work areas in which visible dust is present. During the dry summer months, pre-watering (i.e., watering before the normal work hours) to soak the work area prior to daily excavation work will be done. Air monitoring (see Appendix A for more details) will be conducted in the work area and on the personnel most likely to breath dust.

2.2.8 Decontamination of Equipment

Any equipment (e.g., excavators, back hoes, scrapers, etc.) that have been used in the remediation areas of the Site will be decontaminated before it is removed from the Site. Decontamination of equipment (i.e., removal of any soil particles from the equipment) will occur on the asphalted vehicle staging area using a pressure washer. The pad will periodically be cleaned and the residual soil will be placed in a PA. Trucks will proceed through the truck wash each time they leave the Site remediation areas. If needed, trucks will also be pressure washed.

2.2.9 Solid Waste

Solid waste (e.g., packaging for construction materials) will be disposed of off-Site at a permitted solid waste landfill. If it is likely that solid waste could be contaminated from Site activities, the waste will be tested to confirm that it can be disposed of as solid waste.

2.3 Facility Specific Characteristics

2.3.1 Operating Facilities

The Site has no operating facilities. The only structures on Site are temporary office trailers and three well houses. The maintenance buildings, clubhouse and other GC support structures will be completed concurrently with the GC construction, but not as part of the remediation. The design of these structures is outside the scope of this RDR.

2.3.2 Force Majure

The Site sits on a high bluff that rises 200 feet above Puget Sound and, thus, there is no potential for flooding. Earthquakes are a potential hazard and have been recorded within the immediate vicinity of the Site (Nisqually Earthquake, 1999). Temperatures as high as 100 degrees F have been recorded in the area. The Site's HASP will contain contingencies and special considerations to address these hazards.

2.3.3 Local Planning and Development Issues or SEPA Information not in RI/RA/FS

Local planning and development issues were addressed in the draft Environmental Impact Statement (EIS) for Site remediation completed on February 18, 2000. This EIS was finalized and approved after public review and comment on July 28, 2000 (Ecology, 2000). No State Environmental Policy Act (SEPA) requirements are outstanding. This EIS included an assessment of the "substantive requirements of local permits."

2.3.4 Permits and Approvals

Table 2-1 presents the ARARs that were evaluated to determine if any permits were required for Site cleanup. All permits will be addressed by ensuring that the substantial requirements are met.

2.3.5 Institutional Controls

Institutional controls are measures undertaken to limit or prohibit activities that may interfere with the integrity of a cleanup action or result in exposure to hazardous chemicals at the Site. Such measures are required to assure both the continued protection of human health and the environment, and the integrity of the cleanup action whenever hazardous chemicals remain at the Site at concentrations that exceed the applicable CL (WAC 173-340-440(1) and (4)).

Institutional controls are a critical component of this proposed cleanup action. Residual contamination will remain on-Site, beneath the cap/cover. Both physical controls and legal and administrative mechanisms will be used to ensure that current and future citizens and wildlife do not come into contact with residual contamination, and that the integrity of the cap/cover containment system is maintained. Institutional controls will take the form of restrictive covenants placed with the deed. The restrictive covenants will limit Site use with the purpose of minimizing disturbance to the cap/cover system, and will prevent any unauthorized excavation on the property.

Deed restrictions to limit Site uses will be imposed for different land uses including commercial, recreational (GC), historical, industrial, and open space. An additional deed restriction will be required for the property inside the GC footprint, limiting this property to that sole use and placing restrictions on activities that could disturb the cap/cover. A deed restriction will also be placed upon the Site to restrict the use of groundwater to non-potable uses only, until such time as it meets CLs.

2.4 Construction Documentation

Construction documentation will include as-builts, a variety of survey steps, and other record-keeping procedures.

2.4.1 As-Builts

As-builts will be generated for each of the construction components in order to document the remedial action as well as to provide a record if such information is needed in the future. As-builts will also be generated for all aspects of the GC construction and the construction of the CAP.

2.4.2 Survey Steps

There are a number of different survey steps that will occur throughout the remedial action. In some cases surveys will be done using a survey crew and a control station. In other cases surveying will be done using a Global Positioning System (GPS). The following survey steps will occur as part of the remedial action:

1. A topographic survey of the areas of the Site that will undergo remedial action was performed using a GPS. This survey was done on 50-foot centers outside the GC and on 25-foot centers inside the GC. This information serves as the baseline elevation of the Site before remediation takes place.

2. Excavated areas will be surveyed after soil is removed. The pre-remediation grid nodes (see Step 1) will be used as the point of compliance to ensure that a minimum of 1 foot of soil has been removed. This survey will be performed using a GPS system.

3. PA elevations will be surveyed using a total station after all of the soil is placed in a PA. This survey will establish the elevation of the PA and will serve as a baseline to demonstrate that the eco-cap meets the performance standard at all grid nodes. If the performance standard is not met, additional cap material will be added in order to achieve the standard at all grid nodes. This survey will also determine the final boundaries of the contaminated material.

4. The elevations in PAs will be surveyed using a GPS after the eco-cap is in place. This survey will establish the elevation of the eco-cap and will serve as a baseline to demonstrate that the human health cap meets the performance standard at all of the grid nodes. If the performance standard is not met, additional cap material will be added in order to achieve the standard at all grid nodes.

5. The elevations in PAs will be surveyed using a GPS after the human health cap is in place. This survey will establish the elevation of the human health cap and will demonstrate that the human health cap meets the performance standard at all of the grid nodes. If the performance standard is not met, additional cap material will be added in order to achieve the standard at all grid nodes.

6. GC infrastructure, such as irrigation main lines and infiltration wells, will be documented via a survey using the GPS.

7. The rough finish grade of the GC will be recorded via a GPS survey.

8. Once the GC is completed, the footprint will be surveyed by a registered surveyor.

2.4.3 Documentation and Record Keeping

During construction, detailed records will be kept of all aspects of the work performed including construction techniques and materials used, items installed, and tests and measurements performed. This information will be documented and captured in the Site files by daily field inspections (including pictures as appropriate), GPS or total station surveys, as well as through the retention of information identifying manufacturers, manufacturing specifications, etc.

Table 2-1 – ARARs and Associated Permit Requirements

Applicable, Relevant, and Appropriate Requirements or Regulation (ARAR)	Permit Required?	Action
The Model Toxics Control Act (Chapter 173-340 WAC).	No	Overriding regulation
Washington State Shoreline Management Act (Chapter 90.58 RCW; Chapters 173-18, 173-22, and 173-27 WAC).	No	
Pierce County Shoreline Management Use Regulation (Title 20).	No	
Pierce County Development Regulations—Critical Areas (Title 18E).	No	
Washington State Hydraulic Projects Approval (Chapters 75.20.100 Through 75.20.160 RCW; Chapter 220-110 WAC).	No	
The Fish and Wildlife Coordination Act.	No	
Endangered Species Act (16 USC 1531 et seq.; 50 CFR Parts 17, 225, and 402).	No	
Native American Graves Protection and Repatriation Act (25 USC 3001 Through 3013; 43 CFR Part 10) and Washington's Indian Graves and Records Law (Chapter 27.44 RCW).	No	Regulations will apply if burial is discovered during remedial action.
Archaeological Resources Protection Act (16 USC 470aa et seq.; 43 CFR Part 7).	No	
Washington Dangerous Waste Regulations (Chapter 173-303 WAC).	No	
Solid Waste Management Act (Chapter 70.95 RCW; Chapter 173-304 and 173-351 WAC).	No	
Water Quality Standards for Surface Waters of the State of Washington (Chapters 90.48 and 90.54 RCW; Chapter 173-201A WAC).	No	
Federal, State, and Local Air Quality Protection Programs.	No	
Department of Transportation Hazardous Materials Regulations (40 CFR Parts 171 Through 180).	No	
Washington State Water Well Construction Act (Chapter 18.104 RCW; Chapter 173-160 WAC).	No	Requirement will be followed during well closure or installation
City of DuPont Regulations and Standards.	Yes	Ecology to ensure that substantial requirements of City Zoning codes are included in design criteria WAC 173-340-710 . See the EIS.

SECTION 3 – HEALTH AND SAFETY

3.1 Health and Safety Plan

The health and safety (H&S) of Site workers and local residents is the highest priority of this remediation. Dust generation represents the highest concern and will require monitoring so that the level of dust generated during soil handling does not exceed allowable levels in downwind areas. Dust control methods (i.e. applying water to work areas prior to and during excavation) will be implemented. The air quality impacts will be monitored to protect Site workers from unsafe working conditions. In addition, work done within 500 feet of the boundary of the Site will require perimeter dust monitoring and extensive dust prevention measures to prevent off-Site impacts. A detailed air monitoring plan is presented in Appendix A.

Personal protective equipment (PPE) appropriate for the type of potential exposure will be worn when appropriate, to reduce worker exposure. Workers will be trained in the H&S procedures appropriate for their respective tasks, and in the operation of equipment (trucks, backhoes, and other heavy equipment), and will comply with the appropriate safety regulations.

Some Site soil will be transported off-Site for disposal. This will add an additional risk of exposure for on-Site workers. This risk will be managed by wetting the soil during handling, paving the centralized storage area, and/or covering stockpiles when not adding or removing material. All truck loads will be covered prior to leaving the Site. Transportation of soil to the landfill will be managed by conforming to applicable Department of Transportation regulations.

The former DuPont Works Project (Project) has established a safety policy that, along with the project specific HASP, outlines the safety requirements of the Companies. This policy is intended to assure the long-term safety of workers and others and is summarized below. In addition to the procedures listed below, the Site has an active H&S program that meets WISHA requirements and regulations. The program includes a written HASP and daily safety meetings. The details of the specific H&S requirements for each remedial action are presented below.

3.1.1 General Policies

The following general H&S policies have been established for the project:

- **Safety is the single most important factor in the work place.** No work will be done on the Project except under the highest safety standards. At a minimum, this means following the rules and restrictions imposed by WISHA, the Occupational Safety and Health Administration (OSHA) and Weyerhaeuser and DuPont Company Safety Policies.

- **Safety is a condition of employment.** All contractors and employees must realize that the practice of unsafe work habits will result in immediate removal from the Site.

- **The project's goal is no incidents, accidents or loss of workdays.** All accidents are preventable. As such, all Project contractors and employees will look for and report unsafe working conditions and personnel to the Project Management Team (PMT) as soon as possible.

- **Safety procedures must apply to all contractors and workers**. All contractors working on the Site have the potential to impact each other. As such, everyone working on the Site must follow the same procedures and precautions.

- **All activities will follow Weyerhaeuser and DuPont Policies and Procedures.** This will include Weyerhaeuser's Incident Investigations Program.

- **All field or construction activities will be audited on a regular basis.** Annual audits will be conducted by an independent or company auditor. DuPont company representatives will perform periodic audits.

- **A safety briefing and debriefing will be held at the start and completion of each phase of the Project.** A safety kickoff meeting will be held at the start of each activity. A debriefing will be held at the completion of each activity.

- **A safety meeting will be held at the start of each work day**. The safety meeting held at the start of each work day will provide the opportunity to discuss the work to be completed, any specific safety issues associated with that work and any observations or safety issues noted during the previous workday.

- **Safety is the responsibility of each employee and contractor**. All workers on-Site must share in making the Site a safe work environment.

- **Each Contractor is responsible for the health and safety of its employees.** The PMT and Project Manager/Site Supervisor (PM/SS) will aid in the development of specific general guidelines but will not oversee the implementation of any H&S program other than their own.

- **Contractors are directly responsible for their subcontractors.** The PMT will assess the safety performance of all contractors, not only by their actions but by those of their subcontractors as well.

3.1.2 Responsibility

Safety is a line management responsibility. The responsibility of each member of the Site organization is presented below.

3.1.2.1 Project Direction

The PMT consists of the following:

- Bob Martin – Weyerhaeuser Company.

- Ron Buchanan – DuPont Company.

- Jeff King - West Shore Corporation, NW.

Responsibilities include overall coordination of Site activities. The PMT has overall responsibility for the safety of operations and the H&S of all personnel. The PMT is responsible

for ensuring that the project is periodically audited to verify compliance with the project H&S program.

3.1.2.2 Project Manager/Site Supervisor

The PM/SS is Jeff King of West Shore Corp. NW. The PM/SS is responsible for field-related activities under the PMT's direction and for maintaining field operations in accordance with project requirements. He is responsible for enforcing daily implementation of the HASP and resolving H&S issues. He will lead the daily Site briefings and make sure that the meetings are documented in the field logbook. He is also responsible for coordinating safety with subcontractors. In particular, the PM/SS will, if applicable:

- Ensure that personnel are aware of the provisions of the Site H&S Program and are instructed in work practices, safety, waste management, and emergency procedures.
- Establish and ensure maintenance of Site work zones.
- Ensure that appropriate monitoring of the work area and personal breathing zone is being conducted. Compliance of workers relative to pre-established personal protection levels will be assessed during these programs.
- Evaluate Site conditions (i.e., weather, chemical, physical) and recommend any modifications to existing levels of protection.
- Ensure that daily safety briefings are conducted.
- Initiate emergency response procedures.
- Exercise stop-work authority in the event of imminent danger to project personnel.
- Resolve any noncompliance issues.
- Conduct regular inspections to determine effectiveness of the HASP.
- Be responsible for maintaining copies of documents (e.g., training, medical, fit test).

3.1.2.3 Contractor Health and Safety Managers

The H&S manager of each contractor is a resource for development of the Site-specific HASP and will be consulted on all related H&S issues that arise in the field, including any changes in the scope of work. The H&S manager will make all final decisions regarding questions concerning each contractor's HASP. He also must:

- Ensure that contractors' personnel are aware of the provisions of their HASP and are instructed in work practices, safety, waste management, and emergency procedures.
- Work with the PM/SS to ensure that appropriate monitoring of the work area and personal breathing zone is being conducted. Compliance of workers relative to pre-established personal protection levels will be assessed during these programs.

- Evaluate Site conditions (i.e., weather, chemical, physical) and recommend any modifications to existing levels of protection.
- Ensure that daily safety briefings are conducted.
- Initiate emergency response procedures.
- Exercise stop-work authority in the event of imminent danger to project personnel.
- Resolve any noncompliance issues.
- Conduct regular inspections to determine the effectiveness of the HASP.
- Maintain copies of documents (e.g., training, medical, fit test).

3.1.2.4 Project Personnel

Project personnel involved in field activities are responsible for:

- Taking all reasonable precautions to prevent injury to themselves and to fellow employees.
- Conducting only those tasks that they believe they can do safely.
- Reporting all occurrences and/or unsafe conditions to the PM/SS.

3.1.3 Site Access

Site access restrictions will be in effect during times of active fieldwork. This is necessary for the safety of the contractors working on the Site, visitors and vendors, and to control Company liability.

3.1.3.1 Access Restrictions

The following Site access restrictions have been put in place and will continue until the end of the Project.

- General Site Access: No casual visitors will be allowed on Site except to visit the Site office. General Site access will be denied to all visitors except as permitted by Weyerhaeuser. If Site access is granted, trained Site personnel will escort the visitor in the Site personnel's vehicle. No personal vehicles will be allowed on Site except for delivery of supplies. No one except those listed below will be allowed in the work areas or outside of vehicles within areas judged, by Weyerhaeuser, DuPont or the PMT, to be unsafe. This policy is in place to protect each individual from potential exposure to contaminants and other safety hazards.
- Work Area: No one who does not have active involvement in the corrective action process will be allowed within the work area. Access to the work area will be limited to Ecology, employees of Weyerhaeuser and DuPont, and their contractors.

3.1.3.2 Site Access Procedures

The Site access procedures include the following:

- General Conditions – Site Visitors and Vendors: All persons entering the Site will be required to check in with the guard at the guard shack. Access outside of working hours will be highly restricted and granted on a case-by-case basis only.

- Additional Conditions – Delivery Personnel: Delivery personnel will remain at the guard gate parking area until Site personnel can escort them to and from their destination. Deliveries to the Site office will be allowed without escort.

- Additional Conditions – Site Visitors and Vendors: All visitors and vendors must remain at the guard shack parking area until they can be escorted to the Site office. At the Site office they may request access to the Site. If granted they will be required to sign the Site Access Agreement and complete a brief orientation on Site safety requirements and hazards. Trained Site personnel will escort all visitors. No personal vehicles will be allowed on Site except for delivery of supplies. No visitors will be allowed in the work areas or outside of vehicles within areas, judged by Weyerhaeuser and DuPont to be unsafe.

3.1.4 Health and Safety Training

All Site workers will have H&S training commensurate with their work. Table 3-1 presents the training that will be required based on specific activities.

3.1.5 Communication

Regular communication is vital due to the multiple tasks being completed during this program. As such, each individual will be supplied with a two-way radio. In addition, one individual from each company and each work crew on Site will be required to carry a cellular telephone.

All contractors will be required to contact Weyerhaeuser or the PM/SS immediately if a H&S incident occurs. The PM/SS will contact the PMT and conduct a full investigation of the incident, following procedures established by the Companies. A report of findings will be issued.

Immediate contact with Weyerhaeuser or the PM/SS will also be necessary in all the following cases:

- Media contact.

- Unauthorized visitors.

- Contact by non-Project individuals.

- Unexpected findings.

Other individuals will also be contacted as required by the Project's Communication Plan.

3.2 General Cleanliness

3.2.1 Clean, Orderly, and Hazard-Free Work Site

A clean, orderly, and hazard-free work Site will be maintained at all times. As a standard practice all Site Contractors will:

- Maintain the work Site in a neat, orderly and hazard-free manner in conformance with all federal, state and local rules, laws, codes, regulations and orders including all OSHA and WISHA requirements, until final acceptance of the work;
- Inspect facilities regularly for hazardous conditions caused by construction activities;
- Maintain the work Site in such a manner as to permit access by other contractors;
- Clean the work Site every workday during the term of their involvement;
- Maintain structures, grounds, and areas of the work Site, free from accumulations of waste materials caused by construction operations;
- Maintain equipment in a safe, working condition;
- Remove dirt, dust, litter, corrosion, solvents, paint, stains, and extraneous markings;
- Remove surplus materials, except those materials intended for maintenance;
- Remove tools and equipment used in the construction; and
- Repair damaged materials to the specified condition, or remove and replace.

3.2.2 Decontamination of Personnel

Personnel who enter contaminated areas of the Site will choose suitable PPE based on the activities that will be undertaken and the associated hazards. Personnel who come into contact with soil will proceed through the appropriate decontamination procedures to ensure that no soil is transported into the clean areas of the Site. Detailed PPE and decontamination procedures are identified in the Contractors' HASPs.

Table 3-1 – Required Health and Safety Training

Individual/Position	Minimum Training Required
Weyerhaeuser Management	24 hours HAZWOPER Training
DuPont Management	24 hours HAZWOPER Training
Weyerhaeuser Employees – Site office visitors only	Safety Orientation
DuPont Employees – Site office visitors only	Safety Orientation
Weyerhaeuser Employees – On-Site, non-work area visitors	24 hours HAZWOPER Training
DuPont Employees – On-Site, non-work area visitors	24 hours HAZWOPER Training
Weyerhaeuser Employees – Work area visitors	40 hour HAZWOPER Training Annual 8 hour Refreshers
DuPont Employees – Work area visitors	40 hour HAZWOPER Training Annual 8 hour Refreshers
Project Manager/Site Supervisor	40 hour HAZWOPER Training Annual 8 hour Refreshers Site Supervisor Training
Project Coordinator – Non-work area, occasional escort	24 hours HAZWOPER Training
Project Employees/Contractors who will work regularly within the Exclusion Zone or may require use of an respirator	40 hour HAZWOPER Training Annual 8 hour Refreshers
Contractors Supervisors – In Field	40 hour HAZWOPER Training Annual 8 hour Refreshers Site Supervisor Training
Site Visitors	Safety Orientation

SECTION 4 – TECHNICAL AND CONSTRUCTION SPECIFICATIONS: REMEDIAL ACTION

4.1 Pre-Construction Tasks

The following tasks will be done prior to the start of work.

1. **Safety Review**: Prior to the start of work the following will take place:
    a. The Site will be inspected by the PMT to determine if measures have been taken to create a safe work environment.
    b. The Contractor's HASP will be reviewed for completeness and compliance with Site, state and federal regulations.
    c. Appropriate H&S training (e.g., HAZWOPER) for all personnel will be established. Without written documentation, personnel will not be allowed to work at the Site.
    d. All individuals must read, understand, and sign their companies' Site-specific H&S plan.
2. **Contractor Mobilization**: Following the authorization to proceed by Ecology, the Remediation Contractor (Active) will mobilize all needed equipment and materials to the Site. The materials will be stockpiled on the asphalt pad formerly used for the soil screening plant so that it will be centrally located. The equipment will be delivered to the equipment containment area.
3. **Inspection of Equipment and Materials**: All equipment will be inspected to look for obvious unsafe conditions by the Contractor and the PMT. All materials will be inventoried against invoices by the PMT.
4. **Archeology Training**: All personnel involved in excavation activities will be trained per the Site Cultural Resources Protection Plan.
5. **Truck Routes**: Truck traffic routing for access/egress outside the Consent Decree Boundary will be presented on a map and discussed. Inside of fence traffic procedures and routes will be presented on a map and discussed.
6. **Communications Proceedures**: Inside the fence, communication procedures using radios will be discussed.
7. **Kickoff Meeting**: A kickoff meeting will be held to initiate construction activities.

4.2 Cultural and Archeological Monitoring

By agreement with the Nisqually Tribe and the Office of Archeology and Historic Preservation (OAHP), all initial excavation work done within zero to three feet of the current ground surface will be monitored by trained archeologists to determine if cultural or archeological artifacts are present. If any artifacts are found, they will be treated in the manner described in the Cultural Resource Protection Plan for the Site. In addition, the Nisqually Tribe will have the option of

having a representative working full-time with the excavation crews and a trained Archeologist to audit the remediation.

4.3 Large Scale Applications

4.3.1 Excavation Methods

Excavation of soils greater than the Site-specific RLs for lead and arsenic will occur by the following methods. All of the material excavated, by either method, will be placed in the PAs within the GC areas and will be rough-graded. Any soil that is found that has concentrations greater than the GC PA RLs will be disposed of off site.

- **Method One: Scraping –** The majority of the shallow soils (up to one foot) will be excavated using self-loading pan scrapers. This method will be used on those areas within Parcel 1 that are not historical or open-space RUs. Some selected excavation could occur within the GC areas. The general scraping process will be:

    - Phase I – The top six inches of soil will be removed, using a self-loading pan scraper.

    - Phase II – The remaining six inches of soil will be graded into a windrow and picked up by the pan scraper. GPS will be used to confirm that the final excavation depth is at least one foot. If verification sampling identifies an exceedence after the initial excavation, then an additional foot will be excavated.

- **Method Two: Selected Excavation** – In those areas not accessible to the pan scrapers (because of topography or other reasons), an excavator will be used to selectively excavate the soil in six to eight inch lifts until the desired depth of one foot is achieved. The excavated soil will be loaded into off-road haul trucks and transported to the PAs for placement. Direct pushing of soil into the PA is also possible within the areas adjacent to the PA and in the glacial kettles (depressions in the surface topography) on the Site. Any soil that is found to have concentrations greater than the GC PA RLs, will be disposed of off site. GPS will be used to confirm that the final excavation depth is at least one foot.

4.3.2 General Excavation Types/Process/Logistics

Three work crews will be used to complete different components of the remediation. The work crews and their functions are as follows:

- **Crew Type 1 (Crew 1) - Sloped Area Excavation**: In those areas requiring mass excavation that are not accessible to the pan scrapers (because of topography or other reasons); a bulldozer will be used to push the top one foot of soil to a collection point. An excavator and off road haul trucks will be used to collect the soil at the collection point and transport it to the PAs for placement. Direct pushing of soil into the PA is also possible within the areas adjacent to the PA and in the glacial kettles (depressions in the surface topograpgy) on the Site. GPS will be used to confirm that the final excavation depth is at least one foot.

    Crew 1 will consist of one D8 dozer and operator, an 892 excavator with operator, three 22-29 ton off-road haul trucks with operators, one laborer, an archeologist and a tribal

monitor. Approximately 179,000 CY of soil will be excavated by Crew 1 and the effort will take approximately 125 workdays.

- **Crew Type 2 (Crew 2) - Scraped Area Excavation:** In areas of the Site where the topography is less than seven % slope, the majority of the shallow soils to be excavated up to one foot deep, will be excavated using self-loading pan scrapers. This work will be done in two lifts of six inches in depth so that archeological monitoring can be effective. GPS will be used to confirm the initial depth, followed by a complete survey to confirm the depth excavated. This method will be used on those areas within Parcel 1 that are not historical or open space RUs.

  In those areas not accessible to the pan scrapers (because of topography or other reasons), an excavator will be used to selectively excavate the soil in six to eight inch lifts until the desired depth of one foot is achieved. The excavated soil will be loaded into off-road haul trucks and transported to the PAs for placement. Direct pushing of soil into the PA is also possible within the areas adjacent to the PA and in the glacial kettles (depressions in the surface topography) on the Site. Any soil that is found to have concentrations greater than the GC PA RLs, will be disposed of off site. GPS will be used to confirm that the final excavation depth is at least one foot.

  Crew 2 will consist of one 14H road grader and operator, three 23 CY scrapers with operators, one laborer, an archeologist and a tribal monitor. Approximately 537,000 CY of soil will be excavated by Crew 2; the effort will take approximately 175 workdays.

- **Crew Type 3 (Crew 3) Secondary Excavation**: Contaminated soils found as a result of verification sampling will be excavated by Crew 3 using the method described above (i.e., using an excavator).

  Crew 3 will consist of one 892 excavator with operator, two 22-29 ton off-road haul trucks with operators and one laborer. Secondary excavations will not require an archeologist or tribal monitor, since the initial soil excavation will have already taken place. Volumes of soil requiring excavation and placement will be determined following verification sampling. GPS will be used to confirm that the final excavation depth is at least one foot below the initial excavation.

4.3.3 Placement Area Construction

Placement areas will be constructed in lifts as the material is received from the scrapers or off-road trucks. A D8 bulldozer will be used to flatten the soils deposited by the scrapers/trucks. Once the volume of soil earmarked for the PA is received, a D6 bulldozer will be used to contour the top of the PA. The contour is approximately 18 inches below GC design grade (to allow for 18 inches of cap). A survey to confirm that the desired grade has been reached will be conducted with a GPS. Once the contouring is complete, the edges and final PA contours will be surveyed by a registered surveyor.

4.3.4 Engineered Cap Construction

The GC will be constructed on the project Site as an engineered cover (cap) for contaminated soil and, if necessary, contaminated debris. The cap will be roughly 80.9 acres of the 180-acre

GC footprint and will cover the placed soils. The cap will be a minimum of 18 inches thick and will consist of two layers--an EcoCap to protect ecological receptors, and a Human Health Cap which, with the EcoCap, will prevent humans from coming into contact with the contaminated soil. The methods that will be used to create the cap are presented in the following sections.

4.3.4.1 Gravel and Soil Cap

The cap will consist of a minimum of six inches of clean soil being placed over a minimum of 12 inches of gravel. In this process, the gravel will act as an exposure barrier to ecological receptors. The clean soil will act as an additional exposure barrier to individuals most likely to be exposed—the GC worker who, on occasion, may find it necessary to install drainage ditches or repair an irrigation pipe.

4.3.4.2 EcoCap Methodology and Specifications

Gravels will be excavated on-Site within ¼ mile of the placement area. Steilacoom Gravels excavated on-Site will be used. There will be no specifications for this material. Scrapers or trucks will be used to transport the gravel to the PA, where a bulldozer will be used to spread it. A GPS survey will be performed to ensure that a minimum of 12 inches of gravel has been placed over all placed material.

4.3.4.3 Human Health Cap Methodology and Specifications

Soils for the Human Health Cap will be excavated from on-Site stockpiles or on-Site burrow areas within ¼ mile of the PA. Off-road trucks will primarily be used to transport the majority of these soils to the PA for placement. A D8 bulldozer will be used to spread it to an initial depth of 18 inches over the contaminated soils with the EcoCap. Additional soils will be added until the depth of the Human Health and EcoCap is greater than 18 inches. Once this thickness has been reached, a GPS will be used to survey the final contours of the cap.

The soils to be used to construct the human health cap will vary in composition but will meet one standard; they will meet all Ecology standards for "clean material." The majority of these soils will be topsoil obtained from off-Site sources and oversize sands purchased off-Site. Site soils may also be used if off-Site soils are not available or financially viable, provided that they meet all Ecology standards for "clean material." No particle size or other geotechnical specifications will apply to these soils.

4.3.5 Compliance Monitoring for Large Scale Applications

For soil CLs and RLs based on exposure via direct contact, the point of compliance is established for soils throughout the Site. Compliance verification samples will be collected on 75-foot centers after the contaminated soil has been removed. A five point composite sample will be collected from zero to six inches BGS and the area represented by the sample (i.e., a box of which the sides are 37.5 feet north, east, west, and south from the compliance point) will be considered to be in compliance when the resulting concentrations are less than the land use-specific cleanup standards. If the resulting concentration is greater than the land use-specific cleanup standards, an additional one-foot of soil will be excavated in the box represented by the sample. No statistics will be used to evaluate compliance. The sampling approach including the sub-sample locations is presented in Figure 4-1.

4.4 Small Scale Applications

4.4.1 No Action – Sequalitchew Creek Canyon and Old Fort Lake

No action (remediation) will occur within Sequalitchew Creek Canyon (excluding the NGRR track bed, and lead related excavations down slope of LR-68) and open space setbacks surrounding Old Fort Lake. LR-68 is the only place where excavation will occur other than the actual track bed in Sequalitchew Creek Canyon. Efforts will be made to minimize logging down slope during this excavation. These are highly ecologically-sensitive areas, and require special consideration for the impacts associated with the cleanup of existing contamination (largely low concentrations) vs. impacts to the local ecology if no action was taken.

4.4.2 Cap

The railroad track bed within Sequalitchew Creek Canyon will be capped with an asphalt cap over existing soils, which contain contaminant concentrations above the open space RL, but below the RL established for this remedy.

4.4.3 Cap/Cover

This alternative involves the same cap/cover process described under *Large Scale Applications: Excavation, On Site Deposition and Cap/Cover,* above, but on a smaller scale. No excavation of underlying soils will occur. This action will apply to the Fort Nisqually Cemetery and locations within other historically-sensitive areas.

4.4.4 Disposal of Contaminated Soils

The majority of MSUs containing non-lead and non-arsenic contaminated soils will require disposal off Site. Soils and/or debris that will be disposed of off Site will be stockpiled prior to final disposition. The following five options will be used for these soils or debris based upon contaminant concentrations and economic feasibility. They are:

- Screening and off-Site Disposal – This is appropriate when the arsenic and lead concentrations are greater than that allowed to be placed under the GC cap and the volume warrants the capital cost of building a soil washing plant. Any soil that is found that has concentrations greater than the GC PA RLs will be disposed of off site. There must be more than 5,000 CY of soil before a screening plant is feasible. It is unlikely that this option will be used.

- Placement in Golf Course Placement Areas – This is appropriate for soils and debris with lead and arsenic concentrations above the Site-specific commercial RLs but below the RLs for the capped areas of the GC.

- General Fill – This is appropriate for those soils and debris that have concentrations below the Site-specific commercial RLs. These soils and debris can be placed anywhere in the future commercial area.

- Solid Waste – Brick and debris that are slightly contaminated but are not hazardous waste will be placed on-Site in PAs. Slightly contaminated solid waste is material where the Lead concentration is less than 118 mg/kg and the arsenic concentration is less than 20 mg/kg.

- Direct Disposal Off-Site – Soil and debris that either cannot be screened or the cost of screening is not economical will be disposed of off-Site.

4.4.4.1 Designation Sampling – Post Excavation Soil Stockpiles

Designation sampling is necessary prior to off-Site disposal. Stockpiles will be sampled as they are created or pre-excavation data will be used to develop an adequate representation of the stockpile. Stockpile testing is to determine the appropriate disposal option.

4.4.4.1.1 Reporting – Off-Site Disposal

Actions associated with off-Site disposal will be documented in the final closure report and will include descriptions of each stockpile, descriptions and results of the field processes, the analytical results of all sampling activities, and the designation of each stockpile or excavated volume. A discussion of methods for management, or disposal procedures for hauling off-Site of any treatment residual and other waste materials containing hazardous substances generated as a result of the cleanup action, will also be discussed. Transportation manifests will be organized in a report format and retained by Weyerhaeuser in a Site file for ten years.

4.4.5 General Excavation Process/Logistics

In areas that require precise excavating (e.g., MSUs), an excavator will be used to selectively excavate the soil in six to eight inch lifts until the desired depth is met. The excavated soil will be loaded into off-road haul trucks and transported to the PAs for placement or, in the case of some MSUs, moved to the stockpile retention area prior to transport to the hazardous waste landfill. This method will be used for the excavation of contaminated soils and debris in MSUs, and also for the areas known or suspected of having undiscovered historical and archeological artifacts.

This work will be done using one 892 excavator with operator, two 22-29 ton off-road haul trucks with operators and one laborer. An archeologist and tribal monitor will monitor the initial excavation, but will not be required in all MSU locations once the top three feet of soil is removed.

4.4.6 Compliance Monitoring for Small Scale Applications

For soil CLs and RLs based on exposure via direct contact, the point of compliance is established for soils throughout the Site. The point of compliance for MSUs and debris areas will be the initial excavation limits (no greater than 50 x 50 foot areas). One five-point composite confirmation sample (zero to six inches BGS) will be collected in every excavation. The area represented by the sample will be considered to be in compliance when the resulting concentrations are less than the Site and land use-specific cleanup standards. No MSU-wide statistics will be used to evaluate compliance.

Contaminated debris occurs in two forms: lead painted metal, wood or brick, and elemental lead. Debris that is painted will be tested to determine if the paint is lead-based. If lead-based paint is present, a representative composite sample of painted debris will be collected and sent to the Project Laboratory for analysis. The results will be reported in mg/kg.

Stockpiles or debris evaluated for lead or lead-based paint will be designated based on the analytical results as follows:

- If the lead concentration is less than 118 mg/kg, the material will be treated as fill.

- If the lead concentration is greater than 118 mg/kg, but less than 4,100 mg/kg, the material will be moved to a PA.

- If the lead concentration is greater than 4,100 mg/kg, the material will be cleaned and/or disposed of off-Site.

4.5 Design – Sequalitchew Creek Railroad Bed

The railroad track bed within Sequalitchew Creek Canyon will be capped with an impermeable cap over existing soils containing contaminant concentrations above the open space RL but below the RL established for this remedy. In essence, this will include asphalt and sub-base over the entire length of the railroad bed, from the toe of the uphill slope to the crest of the downhill slope. This RDR includes only that work within the Consent Decree Boundary; the remainder of the track bed will be remediated as an independent action. The process to complete this work is discussed below.

4.5.1 Preparation

The following preparation will be required to complete the remedy:

- Clearing and grubbing, which consists of removing tree branches and brush that obstruct or overhang the trail, cutting and removing wind fall trees that obstruct the trail, removing the danger trees adjacent to the trail, and disposal of all removed materials (e.g., woody debris) along the creek side slopes.

- All steel rails and wood ties will be removed and stockpiled in the previously-excavated section of the burning ground.

- The trail sub-grade will be prepared to a width of 12 to 25 feet by grading and leveling and stabilizing with on-Site sand and gravel.

- Uphill eroded and/or slide areas will be stabilized with Ecology Blocks if necessary. The block foundation will be excavated to one foot below the trail sub-grade. Blocks will be installed to a maximum of four blocks high and one block beyond the slide at each end and will be backfilled with quarry spalls. Perforated pipe will be installed behind the wall at the base if water is present.

- The trail will be widened where necessary, to a minimum of 12 feet using quarry spalls for the embankment material. The spalls will be keyed into the existing slope so that an approximate 1:1 or flatter fill slope can be constructed.

4.5.2 Drainage

Existing culverts will be replaced with 12 and 18 inch corrugated metal pipe (CMP) where required. Pipe outfalls will be located in the same place as the existing pipe to minimize erosion at the outfall. Pre-cast concrete inlet boxes will be located at the inlet end of the culvert in the ditch line. The inlet boxes will facilitate collection of the water in the drainage ditches and cleaning the culvert pipes.

For portions of the trail where water seeping from the cut slope on the uphill side occurs, a shallow trench excavated approximately 18 inches below the trail sub-grade will be installed. Fabric will be placed in the bottom of the excavation which will be filled with crushed quarry rock with no fine material. The rock will be covered with Filter Fabric so that the fine material from future hillside erosion will not clog the voids. The excess excavated material will be placed along the slope on the downhill side of the trail.

4.5.2.1 CAP/Cover

An asphalt cap will be installed over the trail in the following manner:

- Crushed Surfacing Base or Top Course will be placed three inches thick over the width of the trail that will be paved with asphalt. The material will be graded and compacted so that the surface water run-off from the surface asphalt pavement will not concentrate and cause future bank erosion.

- Asphalt Pavement Class B will be placed a minimum of two inches thick on the prepared trail surface. The rock ditches will not be paved over.

- The base course will be a minimum of six inches of two-inch minus base course material.

4.5.2.2 Quality Control Testing

Periodic measurements will be done on the thickness of the laid asphalt and sub-base to ensure compliance with specifications.

4.5.2.3 Operations and Maintenance

The goal of the remediation in Sequalitchew Creek Canyon is to return the area to as "natural a condition" as possible while completing a remedy that is protective to humans and the local ecology. As such, little or no maintenance will be done on the finished surface of the cap. The drainage systems will be maintained until Sequalitchew Creek Canyon is transferred to Quadrant.

4.5.2.4 Ecological Impacts

Implementing environmental controls as well as limiting excavation work to the NGRR track bed will minimize ecological impacts to Sequalitchew Creek Canyon. Environmental controls will include silt fences and erosion controls.

4.5.2.5 Compliance Testing

Sequalitchew Creek Canyon NGRR and LR-68 post-excavation composite samples will be collected from zero to six inches BGS, and the area represented by the sample will be considered to be in compliance when the resulting concentrations are less than the Site- and land use-specific cleanup standards. No RU-wide statistics will be used to evaluate compliance. Five-point composite confirmation samples will be collected every 75 feet along the NGRR and will occur within the excavation only. This will result in 75 x 25 foot boxes with one five-point composite in each box. The five point composite sample will be comprised of one sub-sample in the middle of the tracks and the other four sub-samples collected on both sides of the tracks, no more than ten feet from the track centerline. LR-68 post-excavation composite samples will be collected from zero to six inches BGS, and the area represented by the sample will be 2,500 ft^2 or less.

4.6 Groundwater

4.6.1 Compliance Testing

Groundwater monitoring for DNT will continue on an annual basis. Once DNT concentrations in a well are below drinking standards for four consecutive sampling rounds, the well is considered to be clean. It is at Ecology's discretion for a well to no longer be monitored. Wells that are no longer sampled will be left open and abandoned on a case-by-case basis after approval from Ecology.

Groundwater samples will be collected from four Site monitoring wells: MW-3, MW-6, MW-19, MW-22 and a new monitoring well (MW-28) that will be installed down gradient of RI Area 25. A duplicate sample will be collected from one well. Groundwater monitoring and laboratory analysis will follow the procedures outlined in the Management Plan for Remedial Investigation/Feasibility Study (Hart Crowser, 1992). Any adjustments or changes to this plan must be approved by Ecology prior to implementation. Reports will be submitted using the same format as in the past.

All samples will be analyzed for nitroamine and nitroaromatic explosives (NAX) by Severn Trent Laboratory Services (STL). The analyses will be performed by STL using EPA Method 8095. Only DNT will be reported. A quality assurance/quality control (QA/QC) review of the data will be performed by Ethix Corporation. Reports will be submitted using the same format as in the past.

4.6.2 Monitoring Well Construction

The Washington State Water Well Construction Act (Chapter 18.104 RCW; Chapter 173-160 WAC) governs the minimum standards for construction, maintenance, and abandonment of wells, including both water supply wells and resource protection wells (e.g., monitoring wells). These regulations will apply to the closure of Site monitoring wells and three production wells (W-1, W-2 and W-3) that may be closed (abandoned) as part of this remedial action and the installation of MW 28, which will be installed down gradient of RI Area 25. This well will be installed under the requirements listed in WAC 173-160-420. No soil samples will be collected during installation.

4.7 Remediation Costs

The Table 4-1 presents the estimated remediation costs.

Table 4-1 – Estimated Remediation Costs

Task	Cost
TOTAL REMEDIATION COSTS	$ 10,995,427
CORRECTIVE ACTION – EXPENSED	$ 10,954,595
ARCHAEOLOGICAL & CULTURAL	$ 727,295
NEGOTIATIONS	$ 40,166
SITE MAINTENANCE AND OVERSIGHT COSTS	$ 50,400
FACILITIES	$ 63,573

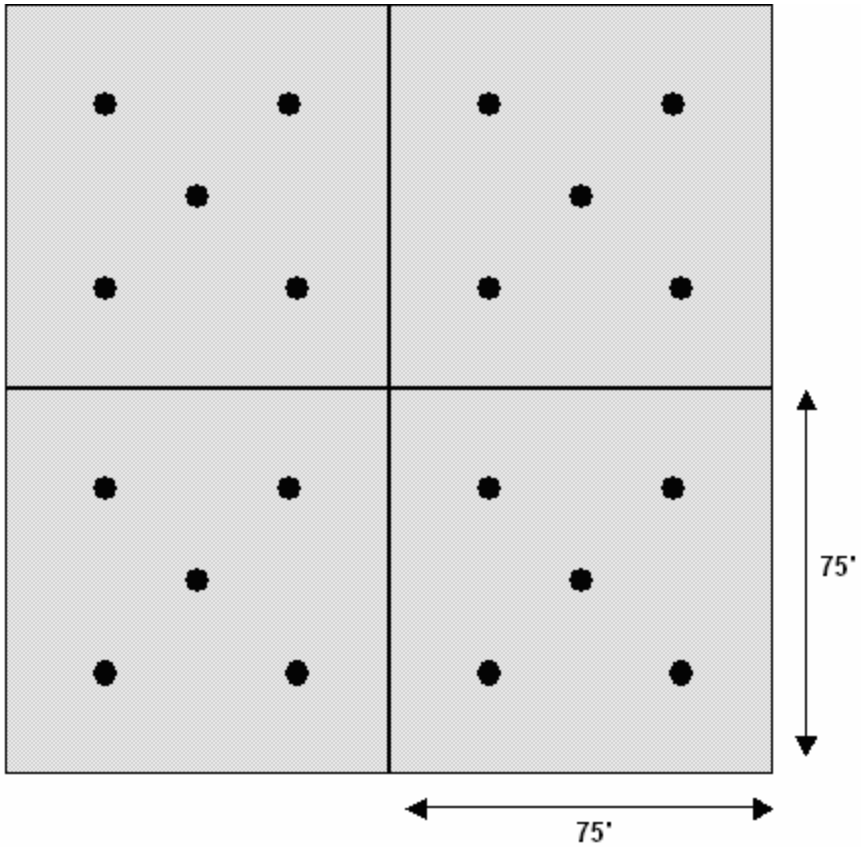
Figure 4-1 – Confirmation Sampling Approach For Large Scale Applications



Note: One sample will be collected from each 75' x 75' box. This sample will be a five point composite. The black dots identify the general location of the sub-samples of the composite sample.

SECTION 5 – TECHNICAL AND CONSTRUCTION SPECIFICATIONS: GOLF COURSE CONSTRUCTION

5.1 Course Construction

Golf Course construction will begin once CUs are satisfactorily remediated and rough grading is completed. It is the design intent that all earth work will balance, meaning the PA capacity and final GC grades can and will be adjusted as necessary. If additional fill is required for grading the GC, it will be obtained from areas adjacent to the work area, but outside of the GC footprint.

5.1.1 References

The latest issue of the publication or standard is listed below for material or operations:

Standard	Description
ASTM D 422	Particle Size Analysis of Soils
ASTM D 698	Laboratory Compaction Characteristics of Soil Using Standard Effort
ASTM D 1556	Density of Soil in place by the Sand Cone Method
ASTM D 2216	Laboratory Determination of Water (Moisture) Content of
	Soil and Rock
ASTM D 2487	Classification of Soils for Engineering Purposes
ASTM D 2922	Density of Soil and Soil-Aggregate in Place by Nuclear Methods
ASTM D 2937	Density of Soil in Place by the Drive-Cylinder Method

5.1.2 Compaction Requirements

Compaction will be accomplished by using approved equipment suited for the type of soil to be compacted. Unless otherwise specified, material will be moistened or aerated as necessary to provide the moisture content that will readily facilitate obtaining the specified compaction with the equipment used. Using the appropriate laboratory maximum dry density test procedures as defined above, each layer of fill and backfill will be compacted to not less than the percentage of maximum density specified below:

Area	Requirement
Common Fill for Fairways and Roughs	85% per ASTM D 698
Select Fill for Tees, Greens, Cart Paths, Lake	95% per ASTM D 698
Foundations and Miscellaneous Structures	95% per ASTM D 698
Common Fill for Embankments	90% per ASTM D 698
Building Sites	95% per ASTM D 698
Parking Area, Road Subgrade	95% per ASTM D 698

5.1.3 Additional Fill

Where fill material is obtained from borrow areas outside of the GC footprint, such areas will be graded to provide complete surface drainage and to blend with the surrounding contours. If surplus excavated material is generated, such material will be placed in areas outside of the GC footprint.

5.1.4 Moisture Control

The water content of the common fill and select fill, will be distributed uniformly throughout each layer of the material prior to compaction. The water content will be within the specified range of the optimum moisture content determined by American Society for Testing and Materials (ASTM) D 698 standard proctor moisture-density test. In general, the contractor will be required to maintain the average placement water content at the standard optimum condition which will be determined by compaction tests. This optimum water content is defined as "that water content which will result in a maximum dry unit weight of the soil when subjected to the compaction tests." Water will be used for the suppression of dust during excavation, including areas being worked and associated haul roads.

5.1.5 Rocks or Boulders

If rocks or boulders (over 12 inches) are encountered during excavation, the material will be collected and stockpiled for future placement.

5.1.6 Architectural Adaptation for Golf Course Construction

The GC designer retains certain architectural freedoms in areas outside of the PAs with respect to minor adjustments to grades, green and tee locations and elevations, quantity and shape of bunkers, etc. This is a normal evolution of the design and creation of a quality GC.

5.1.7 Quality Control Testing

Field density testing for all sub-grade areas and embankments may be performed by nuclear methods, ASTM D 2922 (AASHTO T-238), in addition to the sand cone or rubber balloon methods. The contractor must supply his own testing for compaction control to assure compliance with the specifications. The contractor QC records are subject to owner review.

5.2 Topsoil

Sand topfill material has been imported and is strategically stockpiled on site for future topsoiling of the irrigated turf grass portions of the GC. Proper management of this resource is essential.

5.2.1 Preparation

All areas to be topsoiled will be reviewed and approved prior to application. Any areas that have become overly compacted during remediation or construction will be cultivated to a minimum depth of four inches and shaped to the originally approved contour. All stones, rocks, debris, etc., larger than two inches in diameter in the top four inches of sub-grade will be removed prior to any topsoil application.

5.2.2 Drainage and Irrigation

Prior to the application of the topsoil, the contractor will have completed drainage and irrigation installation and the sub-grade will be restored to the original sub-grade contour of the GC.

5.2.3 Grade Stakes

Grade stakes will be installed at a minimum of 100 feet on center for controlling the required minimum uniform depth of topsoil throughout the GC.

5.3 Rough Shaping

Rough shaping includes the formation of all GC contours and features prior to the application of topsoil. All rough shaping to be performed during and after excavation will be in accordance with GC grading plans.

5.3.1 Equipment

Bulldozers (JD 850 or D6 Caterpillar, six-way blade), shapers, excavators and backhoes will be used for rough shaping operations. A Class 'A' shaper will be used for the formation of all tees, greens, bunkers and other GC features.

5.3.2 Fairway and Rough

Rough shaping of fairways and roughs will provide positive surface drainage to designated collection, conveyance and outlet areas. Continuous verification will be required at all times during the various grading operations (rough and finish shaping), drainage and irrigation installation, as well as topsoil placement and soil preparation phases of the project to ensure the appropriate gradients.

All stones, rocks and/or debris two inches in diameter and larger will be removed from areas that will not receive topsoil. This removal will be accomplished with stone pickers, rakes or any other devices that do not disturb the integrity of the approved sub-grade.

5.3.3 Tees

Tees will be constructed as follows:

1. Tees will be built to follow contour plans, ensuring that tee forms blend smoothly into the natural, surrounding terrain. All filled areas will be compacted to 95% as specified so that no future settling will occur. Fill soil will be compacted with adequate moisture added throughout the grading process. The last three feet will be placed in lifts not exceeding six inches with necessary compacting and moisture to achieve the mandatory compaction of 95%.

2. Tee platforms will be constructed a minimum of three feet wider than the area indicated on the plan, continuously around the perimeter.

3. Sub-grade gradient of tees will be a minimum of 2% and flow toward perforated drain lines per plans and details.

4. As-built drawings for tee outlines, sub-grades elevations, and perforated drainlines will be submitted for review and approval prior to application of tee mix. Tee mix is composed of the approved sand for green construction without organic material. The finish grade of the tee surface is to be completely flat. The minimum depth of the imported sand will be four inches.

5.3.4 Greens

Greens will be constructed as follows:

1. The putting surface and green surroundings will be shaped as a finished contour prior to the excavation of the green core.

2. The greens will be constructed in the presence and under the immediate direction of the golf course designer. Recording and verifying of all spot elevations and contours will be done. As-built drawings of the green at a scale of 1" = 30' with spot elevations on a 15-foot grid will be provided.

3. The excess material from the green core will either be placed outside of the GC footprint or be displaced in the areas surrounding the green as directed.

4. The green core is to be built eight inches below the surrounding sub-grade to allow for the importation of specified topsoil. This allows for a four-inch layer of specified drain gravel and a 12 inch layer of greens mix. Should a 'choker' layer be required, the depth of the core will be increased by two inches.

5. Once the sub-grade has been approved, the various layers of the putting green will be placed at uniform depths to identically parallel the originally approved sub-grade contour. Finish grade tolerances will be plus or minus one inch.

5.3.5 Sand Bunkers

Sand bunkers will be constructed as follows:

1. Sand Bunkers will follow the design in size, shape and depth and are to be constructed under the immediate direction of the golf course designer. It will be necessary to construct the bunker utilizing bulldozers and excavators as well as handwork to achieve the desired contour and edge conditions.

2. After bunker sub-grade has been approved, an exit drain line will be installed in the low point. Exit drain lines beyond the perimeter of the bunkers will be non-perforated pipe with trenches backfilled and compacted with select site soils as specified for carry-off pipe for fairways and roughs.

3. The sub-grade form of the bunker floor will be slightly concave and the perimeter edges will be parabolic curves of varying heights.

5.4 Features Construction

5.4.1 Tees

1. Fine Grading and Topsoil – Prior to the application of tee mix and surrounding topsoil, the Contractor will verify sub-grade for positive surface drainage meeting minimum grade requirements. Care will be exercised that no water will be trapped around the tee after topsoil has been applied. Tee banks will be of constant gradient with no grade breaks between surrounding slopes and tee mix.

2. The same sand material as specified for the greens (without the organic material) will be spread on the tees at a minimum depth of four inches when water has settled, compacted and floated.

3. Tee tops to be level. "String lining" of all tee surfaces will be used for verification.

5.4.2 Greens

5.4.2.1 Laboratory Tests

Drain gravel, coarse sand, and green's sand have been submitted to an approved testing facility for analysis and recommendations for use in the construction of United States Golf Association (USGA) putting greens.

5.4.2.2 Standards

The method of construction will conform to a modified version of the ***"USGA Recommendations for a Method of Putting Green Construction,"*** 1993 Revision, due to specific regional site adaptations.

It will be noted that layers of materials above the sub-grade consist of a uniform layer, four inches in depth, of specified drain gravel, a uniform layer two inches in depth of specified coarse sand (optional depending upon approved laboratory recommendations), and a uniform layer 12 inches in depth of specified greens mix.

1. Plastic Interface - To prevent capillary water movement between the greens mix and surrounding site soils, a plastic liner will be installed to provide a vertical interface with the putting surface. The plastic will be 0.030 mm x 450 mm H.D. polyethylene liner. The plastic will be placed vertically around the cored sub-grade so that the top coincides with the height of the finished grade and will be staked at ten-foot intervals, per manufacturer's recommendations, to ensure that it remains in proper position during filling operation.

2. Copper Wire - Attach a continuous strand of #14 coated copper wires to stakes around the perimeter of the green, as called for on the construction details.

3. Gravel Base – After completion of drainage installation the entire sub-grade will be covered with a layer of clean, washed gravel or crushed stone to a uniform thickness of four inches.

4. Very Coarse Sand Layer- If a discrepancy of more than seven diameters (as determined by the approved USGA-recommended testing lab) exists between the sand top mix and gravel base the following applies: a two inch layer of coarse sand is then to be provided and spread over the entire gravel base prior to application of greens mix.

5. Greens Mixture - The greens mix will be in accordance with recommendations made by a testing laboratory. The analysis of the test of the mixture is to be submitted to the designer for written approval prior to delivery to project site. The USGA Recommendations for the particle sizes of sand for greens mix is as follows: *Total sand particles should exceed 92% of the mix.*

Classification	Sieve Size	Percent Passing
Gravel	2-3.4 mm	<3%
Sand (Very Coarse)	1-2 mm	<10%
Sand (Coarse)	0.5-1 mm	60% minimum
Sand (Medium)	0.25-0.5 mm	combined
Sand (Fine)	0.15-0.25 mm	<20%
Sand (Very Fine)	0.05-0.15 mm	<5%
Silt	.002-.05 mm	<5%
Clay	<.002 mm	<3%

6. The initial rate for greens mix will be between 12 inches and 24 inches per hour of saturated hydraulic conductivity. The final greens mix recommendations will be based upon the initial conductivity rate of the sand and the recommended proportion of organic material required to meet the combined initial rate as referenced above.

7. The greens mixture will be composed of the approved sand and organic material. The organic material will be derived from Canadian Sphagnum peat moss. All mixing and blending of materials (sand and organic) will occur prior to delivery to individual greens. After mixing, samples will be sent to a testing lab to ensure that the mix meets the recommendations of the testing facility. This will be performed at a minimum of every 500 tons of mix production.

8. Physical properties and performance characteristics approved by the testing laboratory must be met with the completed mix. Variations of 10% will be allowed with the percolation rate.

9. Greens mix will be transported to the greens in dual axle truck vehicles and deposited on the inside perimeter and spread by bulldozer. Special care will be taken in cleaning and removing any soil from the tracks of the equipment prior to operations within the green. Equipment will only be operated over areas with the full depth (12") of the greens mix in place. The depth of the sand will continually be probed to achieve the identical sub-grade and maintain the integrity of the green surface. The green will then be completely water-settled and compacted.

10. Under no circumstances will loaded rubber-tired vehicles or dump trucks be allowed on the gravel base prior to or during the spreading of the top mix. Existing perimeter drain lines and irrigation lines (if installed) must be clearly marked so that they are not crushed by sand trucks or other equipment.

11. Grade stakes spaced at frequent intervals on the green site will be helpful in indicating the finished depth of the soil mixture. Finishing the contour of the green will require the use of a level or transit, as well as sand pro and hand raking.

5.4.3 Bunkers

1. Final shaping of the bottoms (concave) and forming of the interior/exterior edges (parabolic curves of varying heights) will be accomplished utilizing excavators and/or backhoe and hand labor.

2. All excess excavated material from final shaping and trench excavations will be removed from the bunker and disposed of as directed.

3. After approval of the bunker's base contour, perforated drainage will be installed with specified gravel backfill. It will be the contractor's responsibility to protect the drainage from any subsequent contamination until such time that the sand is placed. This will be accomplished by installing filter fabric securely anchored at 20 inches on center along each side of the drainline.

4. Bunker sand will meet the following particle size. Total sand particles need to total a minimum of 97%. The sand will be sub-angular, medium sphericity in particle shape and tan in color.

Classification	Sieve Size	Percent Passing
Gravel	2-3.4 mm	0%
Sand (Very Coarse)	1-2 mm	<2%
Sand (Coarse)	0.5-1 mm	75% minimum
Sand (Medium)	0.25-0.5 mm	Combined
Sand (Fine)	0.15-0.25 mm	<20%
Sand (Very Fine)	0.05-0.15 mm	< 3%
Silt	.002-.05 mm	<2%
Clay	<.002 mm	<1%

5. No sand installation will be performed prior to approval. The material will be spread evenly throughout the bunker at a settled depth of not less than four inches and not more than six inches.

5.5 Cast-In-Place Concrete Cart Paths

5.5.1 Alignment

Cart path alignment as indicated on the plans is general. The actual location of all cart paths will be as directed in the field.

5.5.2 Surface Water

In many instances the cart path is being utilized as a diversion for surface water runoff. The cart paths will be positioned and constructed in a manner as to prevent water inundation or ponding. Surface runoff that is being diverted will be collected in drain inlets along the outboard or non-turf grass edge of the cart path. The minimum cross gradient for paths will be 2% and the maximum cross gradient will be 4%.

5.5.3 Sub-Grade Composition

Sub-grade composition will be as follows:

1. Sub-grade beneath cart paths will be compacted to 95% maximum density (ASTM D-698).

2. Construction of the cart path includes sub-grade compaction, six inches of gravel base course or underlayment and four inches of cast-in-place, reinforced, concrete.

3. Compaction testing of both the sub-grade and gravel base course will occur. Results of these tests need to be reviewed at each stage of construction, and prior to advancing to the next stage.

4. Minimum width of the gravel base course will be 8.8 feet, with a uniform extension of four inches on each side of the path beyond the cast-in-place concrete.

5.5.4 Finish Grade and Width

The finish grade and width will be as follows:

1. Finish grade adjacent to the cart path for both turf and non-turf edges will be minus one inch.

2. Cart paths will be a uniform width of eight feet. All cart path turnarounds will have a minimum diameter of 28 feet to the outboard edge of the path.

5.5.5 Forms

Forms will consist of the following:

1. Form lumber or steel (including board and batten forms) will be straight, uniform width and thickness, free from knots, offsets, holes, dents, and other surface defects. Lumber must be sufficiently sealed to prevent absorption of water, form release agent, etc.

2. Stake and secure wood forms in place with steel bars at intervals to prevent form deflection during placement of cast-in-place concrete.

3. Do not remove or disturb forms until the concrete has attained sufficient strength to safely support all dead and live loads. Use care in removal to avoid surface gouging, corner or edge breakage, and other damage to the concrete.

5.5.6 Cast-in-Place Specifications

The cast-in-place specifications are as follows:

1. Cast-in-place concrete to be reinforced with welded wire fabric that has (six inches x six inches) electrically welded cold-drawn wire (70,000 PSI yield point) or fibermesh synthetic fiber material. Wire reinforcement will be installed in longest practical lengths, and adjoining pieces will be lapped in 2 meshes plus end extension of wires, but not less than 12 inches. Welded wire mesh will be placed on acceptable chair blocks at 1 and 1/2 to 2 inches above the gravel base. Fibermesh will be incorporated in the mix at the rate of 1.5 pounds per CY prior to leaving the plant. The fiber quantity and manufacturer will be noted on each batch ticket provided by the concrete provider.

2. Cast-in-place concrete curbs (four inches high by four inches wide) will be formed and poured in an integral manner with the adjacent flat work. In situations where welded wire mesh is utilized for reinforcement and, when a curb is present, it will be evenly bent at 90 degree angle so that it is evenly imbedded in the curb after concrete installation. Cast-in-Place concrete will conform to ASTM C 94, using 3/4 inch maximum-size aggregate, and having a minimum compressive strength of 3000 PSI at 28 days.

5.5.7 Hot Weather Concreting

Hot weather concreting will conform to American Concrete Institute #305, "Recommended Practice for Hot Weather Concreting," in addition to the following specifications:

1. Precautions will be taken when ambient air temperature is 90^{o} F or above. These measures may include installation of wind breaks, shading, fog spraying, sprinkling, or wet covering of a light color.

2. Temperature of concrete when placed will not exceed 85 degrees.

3. Forms and reinforcing will be cooled to a maximum of 90 degrees by spraying with water prior to placement of concrete.

4. Prevent plastic shrinkage cracking due to rapid evaporation of moisture.

5. Set-retarding and water-reducing admixtures may be used when ambient air temperature is 90 degrees or above, to offset accelerating effects of high temperature.

5.5.8 Joints

5.5.8.1 Expansion Joints

Install mastic or felt material perpendicular to the length and curvature of the path at maximum of 40 feet on center.

5.5.8.2 Contraction Joints

Install contraction joints at ten feet on center perpendicular to the length and curvature of the path. Contraction joints can be either 'tooled' or 'saw-cut' at seven days.

5.5.9 Execution

The following procedures will be followed prior to pouring of concrete:

1. Form work will be inspected.

2. Sub-grade compaction tests will be performed.

3. Inspect re-enforcement for proper position and securement.

4. Verify expansion joint material and that other embedded dowels are in the proper position.

5. Moisten sub-grade prior to placement, but do not cause water to pond or muddy, or soft spots to appear.

5.5.10 Finish

The concrete will be finished as follows:

1. Immediately after pouring concrete, it will be spread, straight edged and bull floated. These operations must be performed before bleeding water has an opportunity to collect on the surface.

2. To obtain good surfaces and avoid cold joints, the size of the finishing crews will be planned with due regard for the effects of concrete temperature and atmospheric conditions on the rate of hardening of the concrete.

3. Finish to coarse broom transverse-scored texture (right angles to direction of traffic) by drawing a broom across the surface. This operation will follow immediately after floating operations.

4. Test surfaces of specified finish will be done for approval prior to concrete installation.

5.6 Finish Grading

Finish grading will occur after drainage and irrigation installations are complete and the specified topsoil has been applied. Ideally, cart paths will be installed prior to topsoil installation. Finish grading includes:

1. Maintenance of continuous, smooth contours with no uneven grade breaks within the GC, including other features such as greens, tees, cart paths, surrounding undisturbed areas, existing trees, etc.

2. Positive surface drainage will be maintained with a minimum of 3% in all instances and will utilize a transit to verify this requirement.

3. Stones, rocks and other deleterious material larger than one inch in diameter will be removed.

Finish grading will be approved prior to advancing to subsequent soil amendments, seedbed preparation and grassing phases. Bulldozers, tractors with disks for cultivation, sand pros, hydraulic box graders, rock pickers, etc. will be available for performing finish grading of the GC.

5.7 Soil Amendments

This section includes minimum requirements and procedures for the initial cultivation of the seedbed and the incorporation of chemical additives for improved agronomic fertility.

5.7.1 Equipment

Tractors with turf tires, Viacon and or Lily Spreaders, agricultural disks or plows, mechanical rock pickers, will be available as required.

5.7.2 Soil Tests

Soil fertility tests will be conducted throughout the GC (minimum one per hole) to determine the need for additional amendments and rates over that specified herein.

5.7.3 Application of Gypsum

Gypsum will be applied at the rate of one ton per acre for fairways and rough areas of the GC, unless amended by site-specific soil tests. Gypsum will be uniformly applied and incorporated into the soil to a depth of at least six inches by disking, harrowing, or other acceptable methods within 24 hours following application.

5.7.4 Application of Dolomitic Lime

Greens and tees will receive an application of dolomitic lime at the rate of 50 pounds per 1,000 square feet and be incorporated into the top four inches with approved equipment.

5.7.5 Starter Fertilizer (Fairways and Rough)

Starter fertilizer will be Lesco Professional Starter Fertilizer (18-24-12) derived from Poly Coated Sulfur Coated Urea, Urea, Diammonium Phosphate, Sulfate of Potash, and Muriate of Potash. It will be applied at the rate of 450 pounds per acre with rotary spreaders as recommended by the manufacturer. Starter fertilizer will be applied 12 hours prior to planting.

5.7.6 Starter Fertilizer (Tees and Greens)

Starter Fertilizer for Greens and Tees - Basic fertilizer should be a 12-24-14 Elite grade product (-14+35 Tyler mesh size) containing monoammonium phosphate as the phosphate source with a minimum of 50% of the total nitrogen, 12% derived from Poly Plus sulfur coated urea and a minimum of 24% from monoammonium phosphate. Fertilizer is to be delivered to the project in un-opened 50 pound bags. Starter fertilizer will be applied at the rate of ten lbs per 1,000 square feet with rotary spreaders as recommended by the manufacturer. Starter fertilizer will be applied 12 hours prior to planting. Iron Plus Elite (Lesco granular micro nutrient package) will also be applied at the rate of six lbs per 1,000 square feet.

5.8 Seedbed Preparation and Equipment

5.8.1 Seedbed Preparation

Seedbed preparation will be performed after areas have been finish graded and the gypsum has been applied and incorporated into the soil as specified. Seedbed preparation includes:

1. Final contouring and 'floating' of all surfaces.
2. Removal of rocks, stones larger than one inch in diameter.
3. Final installation and compaction of sprinkler heads, quick couplers, valve boxes.
4. Final testing and programming of irrigation heads and controllers with radio control; and orientation in presence of owner's golf course superintendent.
5. Repair and completion of transition grades between tees, greens, bunkers, lakes, cart paths and their surroundings.
6. Verification of minimum gradients for proper drainage.
7. Flushing of drainage system and installation of drain inlets.

5.8.2 Equipment

Tractors with turf tires, culti-packers, and sand pros with various attachments, drag mats and drag floats, mechanical rock pickers, disks/harrows, pendulum and rotary spreaders, etc., will be available as required to perform the above operations.

5.8.3 Leveling and Preparation

All undulations or irregularities in the surface resulting from tillage, fertilizing, liming, or other operations will be leveled and floated to a smooth, finished grade with no water-holding pockets. Multiple operations will be required over the areas to be seeded. These will include passing in small, circular directions over all areas with culti-packers, drag floats, sand pros with rakes and drag mats, etc. Hand labor and raking will be used in those areas where the use of equipment maybe constricted. The final seedbed must be smooth and sufficiently soft in order for the seed to be planted therein (85% compaction or less).

5.9 Grassing

5.9.1 Material References

Seed will be labeled in accordance with United States Department of Agriculture Rules and Regulations under the Federal Seed Act and state seed laws. Seed will be furnished in sealed standard containers unless exception is granted in writing by the contracting agency. Each seed container will bear the date of the last germination, and that date will be within a period of six months prior to commencement of planting operations. Seed which has become wet, moldy, or otherwise damaged in transit or in storage will not be acceptable. The type and minimum percentage-by-weight of pure, live seed will be as follows:

Type/Minimum Percentage-by-Weight	Percentage
Purity	98%
Live Seed	90%
Weed Seed	0%
Poa trivialis	0%
Poa annua	0%

5.9.2 Grass Types and Seeding Rates

Seeding will be done at the following rates:

1. Greens: Penn A-4 Creeping Bentgrass at a seeding rate 1.5 lbs/1,000 square foot

2. Tees: Alliance Perennial Ryegrass blend, seeding rate 15 lbs./1,000sq.ft.

3. Fairways: 100% Alliance Perennial Ryegrass blend
   Seeding rate 300 lbs./acre.
   50% Alister Colonial Bentgrass
   50% Glory Colonial Bentgrass
   Seeding rate 50 lbs./acre

Ryegrass and colonial bentgrass should be seeded separately, and done at different times or in a seeder with separate bins.

1. Roughs: 100% Alliance Perennial Ryegrass blend
   Seeding rate 450 lbs./acre.
2. Secondary Rough/Revegetation: 100% Bonny Dunes Fine fescue blend
   Seeding rate 75 lbs./acre

5.9.3 Inspection and Tests of Seed

Seed will be obtained from an approved seed distributor. Triplicate signed copies will be furnished of the vendor's statement certifying that each container of seed delivered is fully labeled in accordance with the Federal Seed Act, and is at least equal to the requirement for seed in the materials paragraph of these specifications. This certification will appear on or with all copies of invoices for the seed. A 1/8 pound sample of each seed type and seed lot will be shipped to an independent registered seed lab for testing. Sampling and testing will be in accordance with the latest rules and regulations under the Federal Seed Act and state seed laws.

Seed that is purchased will be labeled in accordance with the U.S. Department of Agriculture and Regulation under the Federal Seed Act and Association of Office Seed Certification Agencies (AOSCA). Any seed not meeting the design specifications will be rejected.

5.9.4 Planting Dates

All seeding will be performed at such time that the climatic conditions and seasons are favorable for the proper growth and establishment for the specified types of grasses. Seeding will commence as construction and weather allow. The approved grassing dates for the project are between May 1st and September 1st, 2005. No turf grass planting will be allowed to occur outside of these specified dates.

5.9.5 Equipment

Tractors with turf tires, pendulum or rotary spreaders, culti-packers and sand pro with rake attachment will be available for seeding operations.

5.9.6 Seeding

5.9.6.1 Greens

All areas will be checked with a transit or hand level to verify a minimum of one-half of one percent (0.5%) positive fall exiting the green surface. The condition of the seedbed will be approved prior to planting. Seed will be drop seeded with approved sowing equipment at the rates listed herein. The seed will be covered to an average depth of 1/2 inch by means of a sand-pro with 'knobby' tires and light rake attachment.

5.9.6.2 Tees

Seed will be drop seeded by approved sowing equipment at the rates listed herein. The seed will be uniformly distributed over the designated areas. The seed will be covered to an average depth of 1/2 inch by means of a sand-pro with 'knobby' tires and light rake attachment.

5.9.6.3 Fairways and Primary Roughs

Seeding will be performed with Lily or Viacon equipment (rotary or pendulum spreaders) pulled with tractors with turf tires. After seed has been applied, the entire area will be driven over with a culti-packer in two perpendicular directions in order to incorporate the seed into the top 1/2 inch of the seedbed. The entire area will then be smoothed again utilizing a sand pro with light rake attachment driven in a continuous circular pattern. Seeding equipment must be loaded while the seeder is on the fairways and a drop cloth used to surround in transport from one fairway to another.

5.9.6.4 Lake Banks and Secondary Re-Vegetation Areas

Seed will be applied with rotary spreaders and incorporated into the top 1/2 inch of the seedbed by use of sand-pro with light rake attachment or by lightly hand raking.

5.9.6.5 Protection

Immediately after seeding, the entire area will be protected against traffic or other use by erecting barricades as needed, and by placing approved warning signs at appropriate intervals.

5.9.6.6 Maintenance

Immediately after all areas have been planted those areas will be sufficiently watered to seal the soil around the seed. Active maintenance of the GC will be initiated following initial watering.

5.9.6.7 Germination

Germination will be evidenced if the seed sprouts and generates leaf growth. Satisfactory germination will be established by evidence of average 85% germination within any particular 10-foot sample. Areas will be selected at random and counted for satisfactory germination, 30 days after planting. Any area not demonstrating satisfactory germination will be replanted.

5.10 Lake Construction

Lake construction will include the following:

1. Lake edge will be laid out with proposed elevations at a maximum of 25 feet on center for review and approval prior to any subsequent excavation and shaping.

2. Upon approval of layout, the lakes will be excavated and the bottom rough shaped to the design contour. The bottom of the lake will have a minimum gradient of 1% in the direction of the outlet structure and the side slopes will be 5:1 gradient to a water depth of five feet and then a 4:1 gradient to the lake bottom. The lake bottom will be smooth and free from all rock and stone greater than 1/2 inch in diameter, objects, vegetation, and stubble. The sub-grade foundation will be compacted to 95% per ASTM D 698 with no abrupt changes or breaks in grade.

3. Lake lining will be accomplished with either polyvinyl chloride (PVC) (minimum 30 mil), or SS-13 (organic polymers) per manufacturer's recommendations.

5.10.1 PVC Liner

If applicable, PVC liners will be installed as follows:

1. Anchor trenches will be 24 inches by 24 inches and be excavated at a constant elevation around the entire perimeter of the lakes, with an approximate setback from normal water level of one meter.

2. All structures, piping, concrete, drains and any associated work will be completed prior to lining installation. All drain line outfalls into the lake will be at an elevation that is 3 feet below normal water level. Pipe "boots" or "sleeves" will be installed as needed for penetrations below water level to maintain the integrity of the liner and lake sealing.

3. Care will be taken in unloading and placing rolls of lining to avoid damage. The location of a panel or sheet will be verified before unrolling and placement to avoid improper

alignment. Sandbags (or similar ballast) are required to keep the panels in place during installation, a minimum of 25 bags per 1,000 square meters prior to placement of protective soil cover.

4. Care will be taken to avoid wrinkles in the seam areas and around mechanical attachments.

5. Pre-fabricating panels reduce the amount of field seaming. PVC field seeming will consist of solvent welding or wedge welding. Lake Liners will be welded by an installer certified by the manufacturer.

6. After the liner has been installed, it will be covered with a uniform layer of select soils (e.g., excess Site sands), 12 inches in depth, compacted to 85% over the entire surface. Care will be taken so that no equipment is operated without the full depth of the soil cover in place. Select soils will be free from all rocks, stones, or any other deleterious material larger than 1/2 inch in diameter.

5.10.2 Clay Soil Seepage Control Lining (Alternative)

A clay soil seepage control lining is an alternative that may be employed and the installation would include the following steps:

1. Sufficient site soils suitable for lake lining as per Item 2 below will be either stockpiled during the mass excavation or imported by the contractor.

2. Seepage Control Lining Requirements – to expedite lining construction, and to meet reasonable water requirement limitations based on economics and conservation, the clay soil lining permeability coefficient should be less than 1×10^{-7} cm/sec. Selected site soils can be treated as per the following procedures to meet this requirement.

3. The side slope of the lake will be fine graded away from the lake edge to the slope indicated on the plans. The side slope and bottom will be constructed to a uniform sub-grade elevation minus the lining thickness shown on the plans. Deposits of sand, gravel or rocks will be removed to a depth of one foot and be replaced with approved site soil compacted to at least 95% relative density by ASTM D1557.

4. Enough approved soil will be spread over the entire surface of the lake bottom and side slopes to achieve a minimum six-inch layer after the compaction procedure of Item 6 below has been followed.

5. Using a rotary-type mixer or disc capable of producing a uniform mixture to at least a twelve-inch depth, thoroughly mix the select soil deposited on the bottom and side slopes of the lake with water containing 25 gallons of WA-13 and 50 gallons of SS-13 per surface acre, to achieve near optimum moisture content. WA-13 and SS-13 are available from Soil Science International, Post Office Box 5429, Glendale, Arizona, 85053, (800) 873-7713.

6. The treated soil layer will immediately be compacted to at least 92% relative density by ASTM D1557 to a minimum depth of six inches. The method of compacting is both

segmented foot and vibratory rollers to achieve the required compaction. All work will be to the satisfaction of the soils engineer and the site representative of Soil Science International. Density tests by ASTM D2922 are acceptable.

7. Subsequent six-inch lifts to achieve the lining thickness shown on the plans will be added.

8. The select soil lining will be kept moist to prevent surface cracking until the lake bottom is covered with soil cement.

9. Filling of the lake will begin as soon as possible after final compaction of the soil cement and soil lining is completed. The filling water will be added carefully to avoid erosion. Two tons of commercial soda ash per surface acre of lake will be added to the filling water.

10. The supplier of SS-13 and WA-13 will have a technical advisor on the job each day that the seepage control lining is being placed, to insure that adequate treatment is accomplished and correct procedure is followed. The technical advisor will have at least three years of experience in placement of chemically-treated and compacted soil linings. The advisor's qualifications (and those of an alternate) will be submitted to the owner for review and acceptance at least 30 days prior to the start of work.

11. The supplier of SS-13 and WA-13 will submit to the owner one pint samples of each chemical product from current production at least 30 days prior to the start of work. In addition, samples of each shipment will be sent to an approved testing laboratory for a repeat permeability test of site soil.

5.11 Irrigation

5.11.1 Irrigation General

5.11.1.1 As-Built/Construction Record Drawing

The As-Built/Construction Record Drawing (CRD) plan will be an original of the irrigation system as constructed. It will indicate the location of all sprinklers, valves (air, isolation, reducing, relief, drain), controllers, wire routing, pipe routing, sizing of both types of routing and field programming. The construction drawing will be prepared with standard AUTOCAD.dwg files, and information will be gathered using the Sites GPS survey equipment.

For the purposes of the As-Built/CRD requirements, the contractor will provide two measurements from the closest sprinkler heads to the following components, and may use controllers if sprinkler heads are more than 100' away. The components are:

1. Isolation valves.

2. Mainline gate valves.

3. Air release valves.

4. Pressure reducing valves.

5. Pressure relief valves.

6. Drain valves.

7. Automatic valves.

8. Provide pipe sizes for all lateral and mainline pipe.

9. All wire splices - (120 volt, 24 volt and communication).

10. Provide 120 volt and communication cable wire paths and sizes.

11. Provide location of any wire route which does not run in a common pipe trench, e.g. from the controller to the pipe trench.

12. Provide notes as to any sprinkler addition, deletion or programming changes from the "As-Staked" plan to the "As-Built/CRD" field notes.

13. All dimensions to mainline change of direction fittings.

14. Note existing utilities, drainage and existing irrigation equipment.

5.11.1.2 Course Personnel Training

Upon completion of the work and acceptance by the owner, the contractor will be responsible for the training of GC personnel in the operation, maintenance, and repair of the system. The contractor will furnish four copies of all available parts lists, troubleshooting lists, specification sheets and catalog sheets to the owner prior to final payment.

5.11.1.3 List of Material for Approval

The contractor will submit four copies of a material list, complete with manufacturers' name and product numbers, four copies of lists of comparable installations in operation, including customer address and location of installation. Any engineering drawings that would alter the system design of the proposed changes will be the responsibility of the contractor to provide. Included but not limited for submittal are:

1. Sprinkler head manufacturer (each type).

2. Weather station.

3. Automatic valve manufacturer.

4. Radio remote control.

5. Automatic control system manufacturer.

6. Quick coupling valves.

7. Piping system manufacturer.

8. Electrical components.

9. Mainline fittings manufacturer.
10. Grounding.
11. Lateral fittings manufacturer.
12. 24 volt connectors.
13. Swing joint manufacturer.
14. 120 volt connectors.
15. Wire manufacturer.
16. Power conditioner.
17. Pump station manufacturer (see pump section).
18. Junction boxes.
19. Isolation valve manufacturer(s).
20. Mainline valve manufacturer(s).
21. Lateral valve manufacturer(s).
22. Drain valve manufacturer(s).
23. Proposed construction schedule.
24. Sprinkler Center for Irrigation Technology (CIT) performance.

All of the above items are to be listed with:

1. Agent and/or local distributor.
2. Local address, phone # and contact person.
3. Manufacturer's warranty.

5.11.1.4 Warranty

The contractor is to provide Weyerhaeuser an irrigation system that is free from defects in material and workmanship for a period to be not less than one year from final date of acceptance. If, during such warranty period, any such product fails due to improper installation or defective material, the contractor will repair the defective component free of charge. The contractor will have 24 hours to respond to the failure. In the event the contractor does not respond within this time frame, the owner will back charge the contractor the same schedule of service fees as provided to him for such repairs.

5.11.1.5 The Companie's Responsibility for Maintenance

It will be the responsibility of the Companies to maintain the system in working order during the guarantee period, performing necessary minor repairs, keeping grass from obstructing the sprinkler heads, protecting against vandalism, and preventing damage during the landscape maintenance operation.

5.11.1.6 Service by Contractor

The contractor will service the system at the Companies' request during the guarantee period. Any work performed which is not covered by the guarantee will be paid for by the owner. The contractor will furnish the Companies with a schedule of service fees.

5.11.1.7 Turn Over Equipment

The following equipment will be supplied by the contractor to the Weyerhaeuser after the final walk-through:

1. Ten one-inch quick coupling valve keys with a one-inch hose swivel.
2. Two operating keys for each type of isolation valve.
3. Four new sprinklers of each model installed with full nozzle range set.
4. Two controller face plates.
5. Four communication modems.
6. Ten full sets of repair fuses and circuit breakers.
7. Ten swing joints of each style and type installed.
8. Two Dickson #PR4150PB24S, 24-hour pressure recorders (1-800-323-2448).
9. Two satellite keys for every controller installed.
10. Five sprinkler on/off keys.
11. Two sets of sprinkler repair tools for each type of sprinkler.

5.11.2 Irrigation Materials

5.11.2.1 Pipe

Pipe sizes will conform to those shown of the irrigation plan. No substitutions of pipe can be made without prior approval. All pipes damaged or rejected because of defects or non-conformance to the specifications will be removed from the site at the time of said rejection. Pipe as indicated on the plan as four-inch to 12 inch pipe will be a gasketed type with internal ring gasket Class 200 PVC or equivalent. Galvanized steel pipe and fittings installed above ground will be Schedule 40 (or equivalent) galvanized steel painted with a rust resistant paint, with a color that will help to blend into the surroundings.

All PVC pipe, while stored on site, will be covered and protected from the sun's UV rays, in addition to the mud or blowing sand. When the pipe is to be transported from the delivery truck to storage, the forks on the lift will be covered with carpet or another material to prevent any deterioration of the pipe. When the pipe is transported from the storage area to the installation area, the bed and sides of the trailer will be covered with carpet or another material to prevent deterioration. The pipe rack supports are not to exceed five feet.

5.11.2.2 Fittings

Fittings will consist of the following:

1. All change of direction fittings for 4 inch and above pipe will be ductile iron.

2. All threaded fittings will be Schedule 80 unless otherwise noted on the plan.

3. All two-inch solvent weld fittings will be Schedule 40 as manufactured by Dura or Lasco.

5.11.2.3 Valves, Valve Boxes, and Wrenches

Mainline gate valves will be resilient wedge seat construction, designed for 150 pounds of cold water working pressure, and will have iron bodies with brass trim. All valves will be of the non-rising stem type, with a two-inch square nut on the stem, American Water Works Association (AWWA) approved or any other valve meeting the above specifications with five-year warranty. The different valves will have the following characteristics:

1. Lateral isolation valves will be of brass construction, non-rising stem, with cross handle as manufactured by Nibco T-113 IRR unless otherwise noted on the plan.

2. Drain valves will be of the type and size as specified on the plan and installed at low points of the mainline along each mainline loop.

3. Each valve placed below grade must be placed in a valve box. The box will be marked "water." All valve boxes will be as noted on the plans.

4. Air air vacuum release valves will be of the same type and size as the ball valve specified in the plan. They will be installed at high points along a mainline loop or in situations where the mainline dead ends.

5. Remote-control valves with pressure regulating valves will be of the type specified on the plan.

6. Four sets of operational keys for each type of valve installed will be delivered to the owner. They will be of sufficient length to operate each valve smoothly and efficiently.

5.11.2.4 Thrust Blocks

Thrust block concrete will conform to ASTM C 94, using three quarter (3/4) inch maximum size aggregate, and having a minimum compressive strength of 3,000 PSI at 28 days. Thrust blocking will be installed in accordance with the plans and specifications.

5.11.2.5 Sprinklers & Quick Couplers

All gear-driven sprinklers or rotary sprinklers within turfgrass areas will be:

1. Rain Bird full circle Eagle 700-E-36-80-ACME or Toro 734 full circle.

2. Rain Bird part circle Eagle 750-E-36-80-ACME or Toro 765 part circle.

3. All quick couplers will be Rain Bird 4NP-ACME or Toro 470 series.

Sprinklers and quick couplers will be of the size and type as indicated on the plan. The performance selection was based on the CIT space performance testing. Sprinklers and quick couplers must meet 1.2 or better scheduling co-efficient (SC) and 85% or better distribution uniformity and Christiansen's uniformity.

5.11.2.6 Field Controllers

The field controllers will consist of the following:

1. All field controllers will be Rain Bird PAR+-TW-PP 48 station field controllers or Toro Network LTC Plus.

2. Field controllers will be installed on approved concrete bases in accordance with the manufacturer's recommendations and connected to the valves in correct fairway, green and/or tee zones at the grades and locations as staked. Each zone will be properly identified, labeled and adjusted ready for use.

3. Field controllers to be manufactured by the manufacturer as listed on the plans, including manufacturer's lightning and surge protection and plastic pedestals.

4. Each station will be equipped with circuit protection consisting of an "On/Off/Auto" manual switch, choke, transorb and replaceable gas pill that shunts high voltage directly to ground. The kit will protect up to 6KV and 3KA surges in accordance with I.E.E.E. standard 587. The kit will also provide protection to the pump/master valve and field common wires.

5. Each controller will have a laminated blueprint of the area controlled attached to the door housing.

5.11.2.7 Central Controller

The central controller will consist of the following:

1. One Rain Bird Nimbus II or Toro Site Pro with T-Map central controller which are designated on the plans, and are in accordance with manufacturer's specifications will be connected to specified field controllers.

2. Central computer components will be warranted for five years from date of installation. They will be supported with a toll-free number with an unlimited number of calls. A 24 hour turnaround service arrangement will be included to provide zero down time. Software and hardware upgrades will be provided at no charge for the warranty period. A support engineer will be assigned to the project and have a system in place to provide support for any problems. A quarterly newsletter will be produced detailing latest upgrades, helpful hints to maximize the system, and address common problems and resolutions.

3. Central computer components will include four Rain Bird FREEDOM handheld radios, remote hardware and remote software for radio access to central control system, with licenses, FCC permits, and error-free radio frequency.

5.11.2.8 120 Volt Wiring

120 Volt wiring will consist of the following:

1. Wire sizes on the plan are for copper wire. Number eight and smaller wire will be solid, #6 and larger to be stranded. All splices will be done with 3M Scotchlok Epoxy Splice kits and located in Ametek box #170140 marked "electrical." Each splice will have a minimum of 20 inches of excess above final grade for future maintenance.

2. All wiring will be done in accordance with applicable electrical codes and manufacturer's recommendations.

3. All wires and circuits will be identifiable by color-coding.

5.11.2.9 Grounding

Between one and three eight-foot copper clad rod(s), 5/8 inch diameter will be driven at every controller location, and a #6 bare copper wire set 150' into an irrigated area. These devices must have a resistance of five Ohms or less to the ground in which it is driven. When the soil conditions dictate, additional grounding equipment may be required to achieve the five Ohms resistance.

The local irrigation materials representative and/or manufacturer's service representative must test, inspect, and approve all grounding prior to operating the system. A list of all Ohms resistance readings by satellite number will be supplied for recording purposes.

5.11.2.9.1 24-Volt Wiring

The 24-Volt wiring will consist of the following:

1. All 24-volt control wires from the controllers to the remote-control valves will be #14 PE or UF/UL approved 600-volt direct burial wire. All 24-volt common wires will be #12 PE or UF/UL approved 600-volt direct burial wire and will be white in color.

2. All 24-volt splices will be done with “3M” DBY kits or “King” One Step Connectors #70-566.

3. Wire will be furnished in 2500' reels and all splices needed for "teeing-off" will be done in valve boxes with a minimum of 20 inches of extra lead wire provided for modifications and future use.

5.11.2.9.2 Communication Cable

The communication cable will be of the type that is compatible with the control system as manufactured by Paige Electric Corp./New Jersey, Regency Wire/Missouri, or Baron Wire/Illinois. Each communication leg will be clearly marked with a different color or striping. Each satellite will have proper supplemental surge protection as per manufacturer’s recommendation.

5.11.2.10 Swing Joints

All sprinkler heads will be installed on Lasco unitized triple top swing joints, as noted on the plan, with O-Ring seals.

5.11.2.11 Sleeving

Sleeving will consist of the following:

1. All piping under roads, or river and creek crossings will be made with Schedule 40 or equivalent galvanized steel or ductile iron pipe, two sizes larger than the mainline.

2. All piping under bridges will be made with Ductile Iron, hung from and supported every five feet along the length of the bridge with drains on each low point.

3. Sleeving under all cart paths will be installed in Cl200 PVC.

4. Wires will be installed in UL approved Schedule 40 PVC conduit for all bridge crossings, road crossings, cart path crossings or other areas that may warrant the protection of the wire network.

5. Any PVC conduit exposed to sunlight will be painted with a UV ray inhibitor to protect it from sunlight and must be installed in such a way that it blends into the surroundings.

5.11.2.12 Weather Station

The weather station will be designed to provide weather information for the various industries and to calculate E.T. (evapotranspiration) using the varying mow heights of the grass and be manufactured by: Weather Metrics, Inc., 14645 W. 95th Street, Lenexa, KS; (913) 438-7666 or equivalent. The standard sensors monitored will include:

1. Temperature.

2. Wind Speed.

3. Wind Direction.

4. Solar Radiation.

5. Rainfall.

6. Barometric Pressure.

7. Relative Humidity.

8. Soil Temperature.

5.11.3 Irrigation Installation

5.11.3.1 Equipment

Equipment to be used in mainline/lateral trenching and back filling include a tracked trencher (digging depth of six-feet maximum, and a width of 24 inches maximum), a water truck and a backhoe loader or excavator.

5.11.3.2 Excavation, Trenching, and Back Filling

Prior to pipe installation, the bottom of trenches must be level and free from any foreign material such that each pipe will be supported uniformly throughout its length. Material to be used to back fill around irrigation pipe will be from existing sand stockpiles. Backfill material will be free from all rocks, stones, or any other deleterious material larger than ½ inch in diameter.

Backfill will be compacted to 95% standard proctor density. All trench excavation will be compacted in six-inch lifts and completely water settled to insure no future settlement. Compaction reports will be submitted. Trenching excavation and back filling will be done as follows:

1. Trenches for the piping system, wiring and allied material will be excavated of sufficient depth and width to permit proper handling and installation of the materials.

2. Trenches for ten inch to 12 inch pipe will be excavated to a depth so as to provide minimum soil coverage over the top of the pipe 36 inches and to a minimum width of 12 inches wider than the pipe size that is being installed.

3. Trenches for four inches to eight inches will be excavated to a depth so as to provide minimum soil coverage over the top of the pipe of 24 inches or as indicated on the plan and to a minimum width of eight inches wider than the pipe size that is being installed.

4. Trenches for two-inch pipe will be excavated to a depth so as to provide a minimum soil coverage over the top of the pipe is 24 inches or as indicated on the plan and to a minimum width of six inches wider than the pipe size that is being installed.

5. Prior to pipe installation, the bottom of trenches must be level and free from any foreign material such that each pipe will be supported uniformly throughout its length.

6. There are two types of clean backfill material: pipe backfill and trench backfill.

7. All pipe backfill will be "select" material imported from existing sand stockpiles as directed. All pipes need to have a minimum uniform thickness of three inches of select material completely surrounding the pipe.

8. The remaining trench backfill material will be excavated site soils free from all rocks, stones, or any other deleterious material larger than two inches.

9. Backfill will be compacted to 95% standard proctor density. All trench excavations will be compacted in six inch lifts and completely water settled to ensure no future settlement. Compaction reports will be submitted.

5.11.3.3 Pipe Fittings

Pipe fittings will be as follows:

1. Suitable tools for safe and convenient handling of the pipe will be used. The interior of all pipe, fittings and valves will be cleaned before being assembled into the piping system and will be kept clean up to the time of completion and acceptance of the project. All

open ends of pipe and fittings must be suitably blocked or covered during lunch hour and at night to prevent entry of ground rodents, leaves, debris, etc.

2. Appropriate pipe fittings must be inserted in the line where the angle exceeds four degrees off center. All male threads on screwed pipe and fittings will be coated with an approved pipe thread compound before being made up. Pipe compound will not be applied to female threads on fittings or valves.

3. Unless otherwise specified or indicated on the drawings, all sharp changes will be made with two 45-degree elbows and a nipple or short length of pipe as the conditions may require.

4. All elbows, tees, and fittings will be suitably thrust-blocked with concrete, or stabilized with EBAA joint restraints to prevent the breaking or blow off of the joint. In connecting bell-ring PVC, the installer will make certain that each rubber ring gasket is carefully fitted in place, free from all foreign objects, and properly seated, and that these rubber rings are not out of position, buckled, jammed, or "fish-mouthed."

5. All road crossings will be made with ductile iron or galvanized steel pipe. Transition couplings' length will be two times the diameter of the pipe and a minimum of 12 inches long.

6. If, at any time, the mainline must drop more than 12 inches to cross a road, connect to another pipe or for any other reason, the drop will be made with steel as shown on the bridge-crossing detail.

7. Solvent weld PVC: Plastic pipe will be installed as recommended by the manufacturer to provide for expansion and contraction.

8. Plastic pipe will be cut with the assistance of a squared-in sawing vise, or in a manner to ensure a square cut. Burrs will be removed prior to installation so that a smooth unobstructed flow will be obtained.

9. Plastic to plastic solvent weld type joints will be made in the following manner:

    a. Thoroughly clean the mating pipe and fitting with a clean, dry cloth. All solvent weld joints on main line piping will use a cleaner prior to solvent application.

    b. A uniform coat of solvent will be applied to the outside of the pipe with a natural bristle brush.

    c. Solvent will be applied to the fitting in a similar manner.

    d. A second, light coat of solvent will be applied to the pipe, after it is quickly inserted into the fitting.

    e. The pipe or fitting will be given a quarter turn to ensure even distribution of the solvent and to make sure that the pipe is inserted to the full depth of the fitting socket.

    f. The pipe will be held in position for 15 seconds.

g. All excess solvent that appears at the outer shoulder of the fitting will be wiped off.

h. The joints will be allowed to set at least 24 hours before water pressure is applied to the system.

5.11.3.4 Testing and Flushing of System

Testing and flushing of the irrigation system will consist of the following steps:

1. Prior to testing, backfilling of all thrust blocks and mid sections of pipe must be made.

2. The entire system will be field tested at 50% more than the normal working pressure for a period of one hour. This must be done prior to completion of the backfilling process. Upon any visual inspection of the ground, should any leak be found, it will be promptly repaired and re-tested until satisfactory. This test will be under static conditions.

3. All electrical circuits will be tested in accordance with the control system manufacturer's recommendations prior to automatic sequencing.

4. Each hole will be isolated and inspected prior to the installation of any sprinkler heads. During this inspection, all the pipe systems will be "flushed" with water such that it flows cleanly without any debris or sediment in the line. Immediately after flushing, the heads will be installed and, subsequently, wire connections will be set at proper angles, grades compacted, etc. This last process will be performed during final seedbed preparation.

5.11.3.5 Thrust Blocks

Thrust blocks will be installed at all tees, reducer fittings, mainline isolation valves, bends, or at the end of all pipelines as called for in these plans and specifications. Thrust blocks will be poured in forming material, placed between solid ground, and the fittings will be anchored. The area of backing will be sufficient to permit no movement whatsoever of the pipe when placed under test pressures for final acceptance.

5.11.3.6 Gear Driven Sprinklers, Rotary Sprinklers, & Quick Coupling Valves

1. All pipelines will be thoroughly flushed before any heads are installed. Pipeline will be tested for pressure and leakage on each line separated by valves, at pressures from 100 to 150 PSI for one hour.

2. Prior to sprinkler and quick-coupling valve installation, swing joints will be clearly marked in the field with appropriate stakes and flagging material to avoid possible damage caused by equipment or personnel.

3. All sprinklers and quick-coupling valves will be installed on triple-top swing joints, and will be set plumb and level with finished grade once seedbed preparation has started, and will be thoroughly compacted as specified (minimum 95% compaction as determined by ASTM 698).

4. In the event that the cart path has not been installed, the contractor will provide extra pipe, a riser, and ten feet of extra 24 volt wire within five feet of the cart path. When the

path is complete, the contractor will be required to install the sprinkler within six inches of the cart path edge.

5.11.3.7 Central Computer and Field Controllers

The central computer will be completely installed, as designated on the irrigation plan and in accordance with manufacturer's specifications, and connected correctly to the specified field controllers.

Pedestals will be mounted on “cast in place” concrete bases in accordance with manufacturer's recommendations, and will be connected to solenoids in correct fairway, green and/or tee zones at the locations and grades and will be properly fitted, labeled and adjusted, ready for use.

5.11.3.8 Control Wiring

1. All wiring to be used for connecting the remote control solenoids to the field controllers, and from field controllers to the power sources and central controllers will be UF or PE/UL approved 600 volt, single solid copper wire.

2. All wire types and installation procedures will conform to local codes.

3. A minimum of 20 inches of wire for an expansion loop will be allowed at each valve-in-head sprinkler and/or each electric control valve for contraction of wire or tightening of wire, in addition to every change of direction fitting.

4. At no place in the entire wire network will the wire be tight. It must be "snaked" into the trenches to provide expansion. It will be bundled every ten feet with electrical tape or wire ties.

5. All wire will be furnished in 2,500-foot reels and all splices needed for "teeing-off" will be done in valve boxes with a minimum of 20 inches of excess for future needs.

6. All 24-volt wiring will be run with, or be in a common trench with, the main or lateral piping system. The only exception is to run the wiring from the controller to the mainline pipe location.

7. All splices are to be made out of the fairway areas and will be placed in an appropriate valve box with a flush gray lid and a minimum of 20 inches of excess for future use.

8. All expansion loops will be formed by wrapping wire at least eight times around a ¾ inch pipe and withdrawing the pipe.

9. Install one control wire to each valve-in-head sprinkler or electric control valve to the designated controller. Two or more valve-in-head sprinklers or remote control valves on the same control wire will not be permitted. All grouping of stations will be done in the control box.

10. Only one common wire will be installed from each controller to the designated valves. No grouping of common wires between controllers adjacent to each other will be permitted.

11. At each valve-in-head sprinkler, the contractor will use an electrical tape on each swing joint to secure wires in a location that will protect wires from damage.

12. One extra #14 wire the length of mainline that each controller operates, in addition to two #14 wires to each quick coupling valve will be installed for future irrigation needs. This wire will be a yellow color, different from any other 24-volt wire colors, and can be used in the future.

13. When more than one controller is located in an area, different colored control wire will be used for each controller.

14. All 220-volt power wire will be installed in PVC conduit and in a separate trench from the mainline at the depth below finish grade as called for in the plans.

5.11.3.9 Surge Protection

Surge protection will be installed on the 115 VAC power wires and on the communication wires. Surge protection will also be provided on all 24 VAC secondary circuits. Grounding will be checked by the local manufacturer's representative prior to operating any part of the system and then recorded.

5.11.3.10 Electrical Service

Electrical service of proper voltage and phase, along with necessary metering, will be available within 30 feet of the pump house. Wiring inside the pump house and for controllers including, but not limited to, installing a panel board, installing the necessary primary disconnect, fuse boxes and controls, electric lights and switches, and attaching wires to the same will meet local codes.

All electrical equipment and wiring will comply with local and state codes and be installed by those skilled and licensed in the trade. Unless governing codes specify otherwise, 24 VAC control wire will be installed.

5.11.3.11 Pump Station

A Flowtronex PSI model VWTP-2500-4-120 (5HP, 4@75HP) packaged variable-speed pumping station rated for 2,500 GPM at 120 PSI at station discharge, 1,800 RPM 380/3/50 full voltage, 20 foot pump length (from top of slab to bottom of pump basket), turbine pump will have stainless shafting, water lubricated line shaft bearings, galvanized strainer, high pressure stuffing box, and vertical hollow shaft drip proof motors.

Vertical Turbine Pump station will include the following features:

1. Custom fabricated pump steel discharge heads with integral air relief & leak-free packing box assembly.

2. 3-1/2 inch silicone-filled pressure gauges with isolation valves.

3. Hose bib connection.

4. Silent wafer check valves.

5. Individually grooved pump discharge isolation valves.
6. Stainless steel pressure transducers.
7. Heat exchanger.
8. Continuous weld around deck plate.
9. Steel grit blast of all piping and structural members.
10. Integral wet well access hatch.
11. Eight inch flow meter spool with data industrial flow sensor.
12. Eight inch station discharge isolation valve.
13. Four inch station relief valve.
14. 10 inch wye strainer with automatic flushing.
15. Box lake inlet screen with SS legs.
16. Motor space heaters.
17. Pump log remote monitoring software.
18. Eight inch flanged x 16 inch plain ends (Z) pipe.

Controls will include:

1. U.L. listing of complete pump station.
2. U.L. listed NEMA 4 starter and control panel.
3. 400 amp main disconnect.
4. Fused motor protection rated for 200,000 A.I.C.
5. Allen-Bradley microprocessor controller with *SMOOTHFLOW* control software.
6. 75HP 380 volt variable frequency drive.
7. Input line reactor (transient suppression).
8. Dual mechanically interlocked output contactors for automatic alternation of pumps.
9. Low discharge pressure shutdown.
10. High discharge pressure shutdown with auto restart.
11. Low water level shutdown with auto restart.

12. VFD fault shutdown with auto restart.

13. Premier grounding package - UL listed 5/8 inch x 10' copper clad ground rod; 4 inch x 96 inch grounding plate with 25feet of #4 bare copper wire; 100 pounds of Power Set ground- enhancing material.

14. Overload shutdown.

15. Individual motor phase failure, phase imbalance and low voltage protection.

16. Dual S.L.A.P. U.L. categories B and C surge and lightning arrestor with total power dissipation of 82,500,000 VA. Maximum clamping voltage - 1,500 volts (200a Pulse, 8*20 m/sec).

17. Lamp test function.

18. Individual run-time monitoring.

19. Automatic alternation of lead pumps.

20. First out fault indication.

21. Automatic Ramp Up feature (ARU) will slowly ramp up to design pressure (1 psig every 4 seconds) when filling lines when restarting after a shutdown or whenever pressure has substantially dropped

22. Automatic Diagnostic Utility (ADU).

23. Operator Terminal Information System (OTIS) for viewing flow, total flow, set point and system pressure, pump station diagnostics, pump run times, and all other registers within the programmable logic controller (PLC). With data logging flow and pressure capability and 253-station event history.

24. On site start-up supervision, station calibration & operator training.

5.11.3.11.1 Prefabricated, Skid Mounted Pump Station

A prefabricated, skid mounted, pumping plant and booster plant complete with automatic control valve, flow meter, filter assembly, all automatic electrical control components and attached hardware as part of the skid assembly will be installed. The pumping system will conform with manufacturer's warranties and service and personnel training specifications in all respects. A complete set of operating instructions and service manuals will be supplied at the time of installation.

5.11.3.11.2 Rules and Regulations

Work and materials will be in accordance with the latest edition of the National Electrical Code (NEC), NEMA, Uniform Plumbing Code, UL, ASME and other applicable state or local laws or regulations. Nothing in the drawings or specifications is to be construed to permit work which would not conform to code. When the specifications call for materials or construction of a better

quality or larger size than required by codes and regulations, provide the quality and size stated in the specifications.

5.11.3.11.3 Inspections/Approvals

The following inspections/approvals will occur:

1. An inspection will occur prior to the installation of the pumping plant at the manufacturer's facility. During the inspection, an evaluation of the system appearance and conformation to the specifications will be completed.

2. A punch list will be used to identify any deficiencies. Corrections will be performed prior to installation and start-up.

3. A complete submittal package will be submitted to verify that the pump station is in complete accordance with the specifications.

5.11.3.11.4 Installation

The installation of the station, pumps, etc. will occur according to the following steps:

1. A manufacturer's service technician will supervise and assist the installation of the station, pumps and motors, and will provide a preliminary check of all components.

2. Hook-up of electrical power will follow local codes. A manufacturer's service technician will inspect and approve the installation or make the necessary changes required prior to start-up.

3. Following hook-up, the connection of the discharge from the pumping station to the distribution system and the filling of the reservoir so that water can be pumped will take place.

5.11.3.11.5 Start-up and Testing

A manufacturer's service technician will start and calibrate the station to satisfy the performance demands and will also conduct training of the operating personnel to familiarize them with the system's operation and maintenance. Operating personnel will also be trained on how to make minor adjustments to the system after the irrigation system installation is complete, even if multiple visits are required during the two-year warranty period.

The complete pumping system will operate without undue vibration throughout the range of operating conditions. The unit will be given a running test of normal start and stop conditions under load. During each test, each pump will demonstrate its ability to operate without undue vibration or overheating, and will demonstrate without question its general fitness for service. All defects will be corrected and adjustments made at the expense of the manufacturer.

5.11.3.11.6 Warranty

The pump station is to be free from defects in material and workmanship under normal use and operation for a period of two years from the date of effective use, or 30 months from date of shipment, whichever occurs first. If, during such warranty period, any such product proves to be defective, the manufacturer will repair or replace the defective product.

5.11.3.11.7 Skid Wiring

All skid wiring will conform to NEC standards. All wiring from control panels to motors will be in solid conduit, with type THHN copper conductors rated at not less than 600 volts AC and of proper size to carry the full load amperage of the motors without exceeding 70% capacity of the conductor. A grounding cable sized to NEC requirements will be included in the rigid conduit. There will be no splices between the motor starters and the motor connection boxes.

The wiring to the flow switches and the water level electrode controls will be l6 gauge, ten strand copper conductors rated at 600 volts AC, contained in rigid conduit supported per NEC.

5.11.3.11.8 Discharge Flow Meter and/or Recorder

Data Industrial, Pocasset, MA, will manufacture flow sensor and flow rate indicator. Series will be compatible with the irrigation system controls (Maxi). The flow sensor will be properly sized as per the manufacturer's recommendations and installed accordingly.

5.11.3.11.9 Pressure Recorder

The Dual-trace pressure recorder installed on the pump station electrical rack will observe control valve inlet and discharge pressure. The recorder will have a 12 inch diameter, 24-hour chart, with an electrical drive. The enclosure will be suitable for outdoor installation with a casketed latching door and a clear plastic window for viewing the chart with the door closed. The recorder will have a pressure range of 0-250; 100 replacement charts will be provided.

5.11.3.11.10 Main Station Fused Disconnect

A three pole main station fused disconnect will be mounted in a separate NEMA 4 enclosure to completely isolate the electrical system from the incoming power. The fused disconnect will conform to the requirements of the NEC or any applicable local code. The main station fused disconnect will have an operating handle on the front of the panel.

5.11.3.11.11 Power Zone

The pump station manufacturer will provide an auxiliary power supply, pre-wired and mounted on the skid. It should be capable of delivering 120 volts, single-phase power, with KVA and breaker ratings as called out in the technical data sheets.

5.11.3.11.12 Station Heater

The pump station manufacturer will provide a three phase, heavy duty, industrial rated heater, with KW rating as called out in the technical data sheets. The heater will be provided with an internal protected disconnect switch, thermostat, and thermal safety overload shutdown. The heater will be pre-wired and securely mounted on the skid.

5.11.3.11.13 Reservoir Inlet Screen

The screen will be of the type listed on the plans, complete with all the controls required to operate the unit as per the manufacturer’s specifications. The screen outlet connection will be compatible with the horizontal induction tube.

5.12 Water Supply

Irrigation water will be supplied to the GC from a production well that is currently in place. The water right has been previously established and the well is capable of pumping 1,250 gallons/hour. The water will be used for irrigation and dust control purposes, only.

5.13 Underpasses

Two tunnel underpasses are being installed in order to provide access from holes one to two and from eight to nine. Tunnel sections are approximately 12 foot wide by 10 foot height. Length of the tunnels will be the full road right-of-way. Drainage from the tunnels will be captured as part of the GC drainage system. Tunnels will be constructed with precast concrete sections, and set on cast-in-place concrete abuttments. Tunnels will be sized for both golf cart and GC maintenance vehicles and equipment. The elevations of the tunnels will be coordinated to facilitate utilities and roads that overlay them. Retaining walls will be constructed on both ends of the tunnels to provide proper grade transition. Guardrails will be required along the tops of the retaining walls for safety. Cart/maintenance paths will be cast-in-place concrete. Drawings SHEET 40 and SHEET 41 present design details for these two tunnels.

5.14 Drainage

Subterranean drainage will be installed throughout the GC for purposes of collecting and conveying storm and nuisance water runoff. The attached drainage plans (see drawings SHEET 8, SHEET 13, SHEET 18, SHEET 23, SHEET 28, SHEET 33, SHEET 38, and SHEET 39 are schematic and convey the drainage concept and are presented for the purposes of quantifying the approximate number of inlets as well as pipe lengths and sizes. Actual layout of the drainage systems will be accomplished in the field to adapt to actual site conditions and GC shaping.

GC drainage consists of the following:

1. Non-perforated drain pipe (four inch to 12 inch) will be N-12 HDPE per ADS with corrugated exterior and smooth wall interior. Non-perforated pipe will be installed as carry-off pipe. The pipe will be bedded (minimum of three inch surrounding) with select backfill material from existing stockpiles, as directed. The balance of the trench will be backfilled and compacted with previously-excavated site soils. All pipe will be installed with copper wire, as detailed. Excess trench spoils will be either uniformly displaced in surrounding areas or removed.

2. Perforated drain pipe (four inch) will be N-12 HDPE per ADS with corrugated exterior and smooth wall interior. Perforated drain pipe will be installed as intercept pipe in tees, bunkers and greens, as detailed. Trench spoils will be removed and disposed of as directed. The full depth and width of the trench will be backfilled with drain gravel (1/8 inch minus washed pea gravel).

3. Perforated panel pipe (12 inches x 1-1/2 inches) will be AdvanEDGE by ADS and will be installed at 18 feet, zero inches on center in all greens within the proposed placement areas. Pipe will be laid flat with the holes down along the PVC liner and will be covered with a minimum of a 4 inch layer of drain gravel (1/8 inch minus washed pea gravel).

4. Drain Inlet will be constructed with 12 inch N-12 risers with drop-in ductile grate per Eagle Golf and Landscape Products, Inc.

5. Catch basin will be constructed with 24 inch N-12 risers with drop-in ductile grate per Eagle Golf and Landscape Products, Inc.

6. Related appurtenances (fittings and connections) to be provided as required.

7. Carry-off pipe (fairways and rough).

    a. Trenches will be excavated with either a backhoe or mechanized trencher. Depth of trench will provide a minimum of three feet of cover between the proposed finish grade and the top of the drain pipe. Trench bottoms are to have continuous positive gradients with no undulations that allow the pipe to become suspended prior to backfill. Unless otherwise directed, drain lines will be installed at a minimum gradient of 1%. All extraneous material such as rocks, stones, roots, etc. larger than two inches will be removed from the trench bottom prior to placement of pipe or backfill.

    b. The pipe is to be embedded with minimum of three inches (surrounding) of select clean backfill from stockpiles, as detailed and directed.

    c. The remaining trench will be backfilled in lifts not exceeding six inches and be completely water-settled prior to application of additional lifts. Select backfill will be free of all rocks, stones or other deleterious material larger than four inches. Trenches will be mechanically compacted with approved vibratory compactors, or wheeled equipment to ninety-five percent (95%) pre ASTM D 698.

8. Intercept Pipe - Greens

    a. Intercept pipe for greens will be included in the unit price for greens under features construction.

    b. Lay out of drainage for approval will be done prior to installation.

    c. Pipe is to be installed at 18 feet on center in a 'herringbone' configuration with perimeter drainpipe(s) in the low exit portions of the green.

    d. Trenches will be a minimum of eight inches wide by 12 inches deep with a minimum gradient of one percent (1.0%).

    e. Specified pipe will be installed on two inches of gravel bedding with the holes in the down position. End caps will be installed on each lateral line, and 90 degree elbows and clean outs will be installed on the main drain pipe as detailed.

    f. No bunkers or surrounding low point drains will be allowed to drain through the green.

    g. All trench spoils will be removed from the interior of the green core and disposed of, as directed.

    h. Drain gravel for green's drainage will be as approved by testing facility.

9. Tee Drainage

    a. Install perforated drain pipe in tees along the long axis of the tee.

    b. Tee sub-grade to slope minimum of 2% towards drain pipe.

    c. All trench spoils are to be removed from tee surface as directed.

    d. Minimum trench width, depth and gradient to be the same as for the greens.

e. Install pipe on two inch of gravel bed and backfill with specified drain gravel.

f. Install clean-outs on the pipe ends, as detailed.

10. Intercept Drain - Sand Bunkers

a. Intercept drainage in bunkers will not be installed until sub-grades are approved.

b. Drainage will be installed along the low point and longitudinal axis of the bunker.

c. Trench excavations are to be removed from the bunkers as directed. Minimum trench width is eight inches by 12 inches in depth. Place perforated pipe on specified gravel blanket two inches deep with the holes in the down position. Backfill with specified gravel. Install caps on pipe ends.

d. Drainpipe and gravel will be protected from sediment contamination prior to placement of sand.

11. Drain Inlets

a. Inlets are to be installed in the low points of the GC as determined during rough shaping process.

b. Upon completion of rough shaping and installation of carry-off pipe, temporary inlets will be installed at low points that consist of elbows, tees, perforated risers (extending a minimum 20 inches above surrounding grade) with gravel backfill.

c. Permanent drain inlets will be installed during the seedbed preparation process.

12. Catch Basins to be installed in the proposed detention areas of the GC as drawn and specified.

5.15 Placement/Revegetated Areas

These areas are within the interior of the GC and total approximately 16.6 acres of the 80.9 acres of placement (measured to toe of human health cap). Another eight inches of select native till will be provided as a final topfill layer or seedbed and planting medium.

During the completion of the GC, these areas will be initially hydroseeded with Bonny Dunes Fine fescue blend at the rate of 75 pounds per acre. Bonny Dunes is a select mixture of *Discovery Hard, Shadow II Chewings, Florentine* creeping red, and *Bighorn* sheeps fescues.

These areas will not have automatic irrigation; however quick coupler hose bibbs will be provided at approximately 100' on center for available water during initial establishment. After establishment, these grasses are capable of sustaining with natural precipitation.

During the grow-in period of the GC and after the native grasses have begun to establish, the revegetated areas will be augmented with a variety of native woodland shrub and groundcover plant materials. **No trees will be planted within the PAs.**

The proposed plant list for augmentation is presented in Table 5-1. All of the plant materials are native to the subject property and provide both habitat and aesthetic value. These plant materials

typically grow within shallow topsoil layers overlaying either denser clay or gravel subgrades, similar to that being created at the Site. Consequently, the root structures of these plants are shallow and develop in the upper soil profiles. It would be very unusual for them to penetrate the gravel layers that are being utilized for the ecological barrier.

5.16 Landscape Areas

The non-placement landscape areas surrounding the GC will be similarly planted. The exception is that some additional flowering and ornamental shrubs will be provided (Rhododendrons/Azaleas, forsythias, winter-flowering hazelnuts, etc), along with several native trees and occasional flowering trees for accent.

Certain areas of the GC will be planted with vegetation. Vegetation will be planted in a manner so that the roots will not impact the placement areas cap. Table 5-1 lists the types of plants and the anticipated sizes.

5.17 Golf Course Costs

Estimated costs for the completion of the GC cap are summarized in Table 5-2.

Table 5-1 – Golf Course Re-vegetation Plant Types and Root Zone Depths

Botanical Name	Common Name	Size	Remarks
Amelanchier alnifolia	Saskatoon Service-berry	6'-10'	Sun, drought tolerant, deciduous white flowers early spring, blue berries
Gaultheria willon	Salal	3'-5'	Sun, drought tolerant, evergreen white/pink flowers early spring
Holodiscus discolor	Hillside Oceanspray	6'-8'	Sun, drought tolerant, deciduous creamy color flowers, extremely hard wood
Mahonia aquifolium	Oregon Grape	4'-6'	Sun, drought tolerant, evergreen yellow flower clusters in spring, edible blue berries
Mahonia nervosa	Cascade Oregon Grape	2'	Sun, drought tolerant, evergreen, similar flowering characteristics M. aquifolium
Philadelphus lewisii	Mockorange	8'	Sun, drought tolerant, deciduous, fragrant white flowers in summer
Ribes aureum	Golden Currant	6'	Sun, drought tolerant, deciduous, yellow flowers, red berries
Rosa nutkana	Nootka Rose	4'	Sun, drought tolerant, deciduous, single pink flowers in June
Rosa woodsii	Wood's Rose	3'	Sun, drought tolerant, deciduous, pink flowers, edible flower and fruit
Symphoricarpos albus	Common Snowberry	3'-4'	Sun, drought tolerant, deciduous, white berries that persist through winter
Vaccinium ovatum	Evergreen Huckleberry	2-3'	Sun, drought tolerant, dark evergreen leaves, bronzy new growth, white flowers

Table 5-2 – Golf Course Construction Costs

Task	Cost
GC CONSTRUCTION COSTS	$ 9,038,409
GC CONSTRUCTION OVERSIGHT - GENERAL	$ 182,200
GC CONSTRUCTION - GENERAL	$ 7,688,219
COURSE CONSTRUCTION (Mass Ex, Rough Shaping	$ 639,728
DRAINAGE	$ 580,784
GREENS, TEES, BUNKERS CONSTRUCTION	$ 707,291
IRRIGATION	$ 1,458,000
CART PATHS	$ 498,960
SHAPING FINAL	$ 176,205
SOIL AMENDMENTS & SAND SCREENING	$ 115,560
TOPSOIL	$ 545,163
SEEDBED PREPARATION	$ 275,400
GRASSING	$ 234,706
LANDSCAPING	$ 540,000
LAKES	$ 268,251
MISC. GC CONSTRUCT.	$ 143,100
DUST SUPPRESSION	$ 108,000
EROSION CONTROL	$ 13,500
TUNNELS	$ 634,197
GC CONTRACTOR MOBILIZATION	$ 23,451
SUPPLEMENTS (Historic and Water Supply)	$ 54,000
WELL IMPROVEMENTS	$ 55,080
PUMPING STATION AND WATER SUPPLY LINE	$ 162,000
INFILTRATION SYSTEM INSTALLATION	$ 31,017
SAFETY - GC (CAPITALIZED)	$ 122,954
FACILITIES - GC (CAPITALIZED)	$ 22,827
SURVEY TASKS - GC RELATED	$ 213,045
PERFORMANCE BOND	$ 65,000
GC GROWN-IN	$ 432,300
SALES TAX (shared)	$ 735,690

SECTION 6 – POST REMEDIATION GOLF COURSE GROW-IN SPECIFICATIONS

6.1 Introduction

The establishment period of the GC is typically referred to as the 'grow-in' period. It is a highly specialized process whereby the turfgrasses are aggressively grown and nurtured from the time of planting to maturity.

The DuPont Works GC will be planted during the optimum grassing window between May 1st and September 15 2005. Approximately one golf hole per week will be planted during this time. Once a golf hole has been planted and irrigated for the first time, it becomes the responsibility of the owner or his contracted maintenance staff to maintain. The GC contractor's responsibilities from that time forward for any particular planted golf hole are relegated to final completion, minor repairs and warranty items.

The DuPont Works GC will be grown-in for approximately 12 months, over one growing season. This is sufficient time to yield mature turfgrass fully resistant to the effects of play while offering ideal playing conditions. Many GCs do not have the luxury of time that is being invested in this project for this process.

The grow-in will include all of the following functions on a continuing basis:

- Irrigation.
- Mowing.
- Fertilization.
- Topdressing.
- Verticutting & Aerification.
- Pesticides.
- Mechanical Practices.
- Miscellaneous Maintenance Practices.
- Record Keeping.

Each of these functions is discussed in the following sections.

6.2 Irrigation

Irrigation practices are broken down into three phases during grow-in. These include germination, post-germination, and the regular period.

6.2.1 Germination Period

Maintaining quality control during the final seedbed preparation, along with the uniform distribution of seed with proper soil contact, is essential for successful planting. After that, the management of irrigation water is the most critical item needed to achieve uniform germination, minimizing any damping off of new plants, potential rotting and drying of seed, as well as erosion.

To that end, no hole will be watered during the germination period without direct visual and physical control of the irrigation system by designated, trained personnel. Holes will only be watered during the daytime for the first three to four weeks, and will be watered multiple times to maintain a continually moist and uniform surface without drying or surface runoff.

6.2.2 Post-Germination Period

The post-germination period begins at approximately two weeks after planting (depending upon the variety of grass and climatic conditions), when the plants have grown to the 3-leaf stage. The number of water cycles is reduced to three or four times daily with slightly longer duration than the five to six cycles during the initial period. As plants begin to develop, the intent is to match available moisture in the soil profile to the depth of the root growth.

All watering during this period continues to occur during the daytime. While programs are cycled through the satellite controllers, it is still important that personnel be present during watering.

Prior to the first mowing, irrigation water is cut back to allow the surfaces to dry sufficiently to support mechanical equipment with minimal wear. All areas will be irrigated immediately after mowing.

6.2.3 Regular Period

After areas have been mowed a minimum of four times, they can then be irrigated during the night via pre-programmed cycles and without direct visual observation. The intent during this period is to deep water the plants, matching root development. Some daytime watering or syringing may be necessary during the first stages of the regular period, depending upon Site specific and climatic conditions. Also during this period the irrigation system for those portions of the GC that have matured sufficiently can be actuated from the central computer, optimizing the hydraulic window and system flow management.

The regular period also includes the micro-management of each individual turf area. This typically occurs after the entire course has begun to mature. This will affect the programming and optimization of the system and will continually require adjustment as the course ages. The grow-in superintendent, through testing and observation, will adapt to micro-environmental conditions which are affected by contour, soils, turf maturity, exposure, etc. Not all areas of the GC are equal nor do they require exactly the same maintenance regimens. This attention to detail will assure a quality product as manifested in healthy turfgrass, while conserving valuable resources.

6.3 Mowing

Mowers are to be inspected, adjusted, and sharpened to provide optimal performance. There are four primary areas that have different mowing requirements.

6.3.1 Tees - To be Seeded with Alliance Perennial Ryegrass Blend

The first mowing will occur at or after the three-leaf growth stage when grass has grown to 1-1/2 inch height. Moisture content of the soils will be reduced so as not to track mowing equipment. Mowing equipment will be lightweight, belt-driven, tri-plex mowers (e.g., National) set at 1-1/4 inches height with solid rollers. Mowing will be repeated when grass is 1-1/2 inches in height, approximately three to four times per week depending upon climatic conditions. After the first five to six mowings, the cutting height will be reduced to one inch and standard mowing equipment (e.g., Reelmaster 3100-D Sidewinder or equivalent) will begin to be utilized.

6.3.2 Greens - To be Seeded with Penn A-4

The first greens' mowing will occur when there is uniform turf coverage at a height from 1/4 to 3/8 inch, and definitely not more than 1/2 inch. The mower should have a smooth front roller. Greens should be rolled in two directions prior to mowing. Clippings should be caught every other mowing, as this will help build biomass that will protect the crown. It is possible to get the desired mowing height within six to seven weeks after the first mowing. These grasses are being maintained by most facilities at $5/32^{nd}$ or $9/64^{th}$ of an inch.

6.3.3 Fairways - To be Seeded with 80/20 mix of Alliance Perennial Ryegrass and Improved Colonial Bentgrass Blend

The first fairways' mowing will occur at the three-leaf growth stage when grass has grown to 1/2 inch to 5/8 inch height. Moisture content of soil is to be reduced prior to mowing so as not to track or leave depressions with equipment. Mowing equipment will be Greensmaster 3250-D triplex or equivalent with a cutting height set at 7/16 inch with solid rollers. Mowing will continue 3 or 4 times per week depending upon climatic conditions. After the initial six to eight mowings and when the irrigation is cycled to the regular period, standard mowing equipment will be used (e.g., Reelmaster 5400D w/8 blade cutting units). Fairway cutting height will be reduced from 7/16 inch growth height to 3/8 inch.

6.3.4 Rough – To be Seeded with Alliance Perennial Ryegrass

The first rough mowing will occur at the three-leaf growth stage when grass has grown to 1-1/2 inches-2 inch height. Moisture content of soil is to be reduced prior to mowing so as not to track or leave depressions with equipment. Mowing equipment will be lightweight, belt-driven, tri-plex mowers (National) set at 1-1/4 inch height with solid rollers. Mowing will be repeated when the grass once again achieves 1-1/2 inch-2 inch height, approximately three to four times per week, depending upon climatic conditions.

After the first five to six mowings, and when irrigation has been cycled to the regular period, roughs will be mowed with standard units, i.e Reelmaster 5400D w/eight blade cutting unit or equivalent. Mowing heights and frequencies will be reduced to one inch from 1-1/2 inches.

6.3.5 Secondary Revegetation – To be Seeded with Bonny Dunes Fine Fescue

Revegetation areas will be periodically mowed, at the discretion of the superintendent, with an out-front deck mower for weed control, normally at four inches.

6.4 Fertilization

Equipment will be calibrated for both output rate and pattern distribution prior to fertilizing. The minimum equipment includes a walk-behind rotary spreader, a tractor mounted or pull behind spreader (either rotary or pendulum-type), and a boom sprayer (primarily for germinated greens). The primary type of fertilizer will be granular of varying size depending upon use (fine granular for greens and larger pellet for fairways and tees) and water soluble. The GC fertilization requirements are divided into three stages: Pre-plant, Initial Grow-in Establishment, and Established Turf Maintenance.

6.4.1 Pre-Plant

The pre-plant stage is the time to correct nutritional needs by application of soil amendments. However, soil tests need to be administered prior to application of soil amenities to determine the proper additives and application rates. Soil tests should be taken after rough grade has been achieved to obtain a true representation of the topsoil nutritional needs. Based on the finding of the soil test, proper amendments (lime, phosphorous, sulfur, etc.) should be added as needed. It is already determined that the topsoil will primarily consist of sand, so almost all plant nutrients will come from applied sources.

Due to the constantly-moist soil conditions during the first two weeks of germination, no equipment will be allowed on the seeded portion. This requires that pre-plant fertilization nutrients be sufficient for two weeks after the grass has been seeded. The most important nutrient to seedlings is phosphorous. A starter fertilizer applied at 1.5-2 lb of phosphous/1000 sq. ft. along with a minimum of one pound of controlled release nitrogen usually provide the necessary nutrient requirements during germination for turf grass. Greens will be fertilized with a granular fertilizer during this stage as well. On a sand-based medium, micronutrients can also be added in granular form.

6.4.2 Initial Grow-In Establishment

Initial grow-in fertilization will follow an established program. After the initial starter fertilizer is applied prior to seeding, the next application is usually necessary when the grass reaches a height of about one inch (turf begins to show signs of nitrogen deficiencies at this stage, usually about two weeks after seeding).

Tees, fairways, and rough will need to be fertilized with a granular fertilizer on an average of once every 14 days until grasses are well established. Fertilizer mixtures will depend upon the grow-in superintendent's analysis of deficiencies. Greens will be fertilized with a combination granular and water-soluble fertilizers during the grow-in stage. Due to the nature of Penn A-4, greens will possibly have to be sprayed with water-soluble fertilizers to achieve the proper nutrients.

Due to the fact that all growing medium is sand, tees, greens, and fairways will require approximately one-third to one-half pound of nitrogen per week. After the first two applications of "starter" fertilizer, phosphorous will be reduced and nitrogen and potassium will be increased. Continual monitoring will determine the need for micronutrients.

6.4.3 Established Turf Maintenance

After the GC has been grown in, a fertilization schedule needs to be maintained in order for grasses to stay healthy. Tees, fairways, and rough will be fertilized with a large Vicon pendulum-type spreader, while greens are done with a sprayer or walk rotary spreader. On average, fertilizing the first year after grow-in will be reduced approximately 25% to 40%, and the year after that another 15% to 20%. As turf grasses become better established and deeper root systems are developed by the plant, less nutrients are needed to sustain it.

Topdressing the bentgrass fairways during the first two years will have an impact on fertilization schedules. Ammonium Sulfate ($AmSO_4$) and/or Ammonium Nitrate ($AmNO_3$) will possibly need to be used in conjunction with topdressing. Fertilizer applications should take place approximately six days prior to any topdressing, to allow grasses to be at maximum growth and recovery time at a minimum.

6.5 Topdressing

Topdressing for both greens and fairways will be done to control thatch, to level surfaces, and to improve root structure. Topdressing should be of the same material as used during construction, or at least of the same particle size.

Topdressing greens is an integral part of maintaining greens' growth and creating optimal playing surface. Penn A-4 greens require weekly topdressing, which will be performed more often during periods of good growth and recovery and less often during winter and times of stress. Topdressing should be preceded by verticutting to remove some of the organic material and open the greens so that the sand may be worked down into the grass.

6.6 Verticutting & Aerification

6.6.1 Greens

Verticutting greens is primarily employed for the removal of organic material. It is also an important factor in maintaining overall plant health by ensuring the correct number of plants per square inch. Regular verticutting keeps greens from becoming puffy, helps to control thatch buildup, and gives topdressing sand ingress to the thatch layer. It is a very important part of the process employed to keep the greens surfaces at the correct firmness for the best playing characteristics, shot receptivity, trueness of roll, and resistance to ball marks.

Aerification of greens is also used for the removal of organic material but, more importantly, to allow better air exchange in the root system and to relieve compaction. As such, verticutting will generally occur prior to topdressing, with the order of work on that day being as follows:

1. Verticut - depth to be determined by the superintendent.

2. Mow - using triplex greens mower with baskets to remove organic material.

3. Topdress - at 1/2 to one yard of appropriate topdressing material for each 5,000 square feet of green.

4. Drag - "Drag in" topdressing sand with either a steel drag mat or coco mat, depending on desired effect.

5. Cleanup - Using a broom, clean the edges of the green as needed.

Aerification will normally occur one to three times per year during normal maintenance. During grow-in, the superintendent will determine aerification needs.

6.6.2 Fairways

On colonial bentgrass, verticutting is used to control thatch by removing organic material, and as a surface-smoothing operation during the grow-in period. For this use, the vertical cutting blades should be spaced about one inch apart, instead of the usual 1/2 inch. This spacing aides in smoothing the surface without damage to the establishing turf.

Aerification of fairways is normal, once the GC has matured, and will typically begin in the second year of growth. The aerification cores will be broken up by mowing or dragging with a steel drag mat to separate the sand from the organic material. This allows the organic material to be removed and the sand conserved in the fairways.

6.7 Pesticides

The goal for the GC is to employ all means of non-chemical pest control in addition to continual scouting and evaluation to minimize the need for any chemical application. These non-chemical pest controls include correct mowing practices, verticutting, topdressing, appropriate timing and rates of fertilizer applications, and proper irrigation practices.

Pesticide use will be determined by the superintendent with reference to the Integrated Golf Course Management Plan. All applications will be in accordance with Washington State pesticide laws, best management practices, and be administered by a licensed operator. All pesticides and chemicals will be stored in an approved chemical storage unit located in the maintenance area.

The need for pesticides will be determined by continual scouting for pests and diseases; pesticides will be applied when acceptable thresholds have been exceeded. Depending on whether the material to be applied is granular or fluid, the appropriate spreaders or spray equipment will be employed. Application rates will be determined by label recommendations and be kept to the minimum required to maintain the pest within acceptable levels.

6.8 Mechanical Practices

In order for the GC to look its best and operate efficiently, proper equipment maintenance is a necessity. All maintenance personnel will be trained in the following equipment maintenance practices:

6.8.1 Washing Procedures

All grass-cutting equipment will be blown off with air prior to arrival at the wash rack. It will then be cleaned with water and inspected for potential problems, leaks, etc. Mowers will then be fueled and the oil checked before being turned over to the mechanic who will check the cutting units for correct height of cut, sharpness, etc., prior to storing the equipment. Any other equipment used will be cleaned in the appropriate manner prior to storage.

6.8.2 Equipment Check

Hydraulic hoses will be checked prior to usage each day, at intervals during work day, and at the end of the day's work after the equipment has been cleaned. Leaks are often difficult to spot during operation, so checking the equipment each half-hour during usage for leaks, hose wear, or other problems is appropriate.

6.8.3 Storage

All equipment and tools will have a designated storage location. After use or at the end of each day, all equipment and tools will be returned to their appropriate place.

6.8.4 Other Maintenance Practices

Preventative equipment maintenance practices, such as oil changes, filter changes etc., will be performed at correct hour intervals, and be monitored by the mechanic. Reel grinding and reel maintenance will be performed as needed (i.e., as determined by the mechanic and the superintendent).

6.9 Miscellaneous Maintenance Practices

Miscellaneous maintenance practices will include the following:

(1) Cart Paths – Cart paths will be swept regularly to remove grass clippings and any accumulated debris. Beginning in the second growing season, cart paths will be edged as required to remove overgrown turf.

(2) Winter Debris – All downed trees and branches will be picked up and properly disposed of from the GC.

(3) Drainage Systems – Drainage systems will be cleaned and flushed, removing accumulated sediments and debris.

6.10 Record Keeping

All maintenance activities during the grow-in period will be recorded on a daily basis to include: area, specific maintenance task, equipment utilized, materials applied, number of personnel, and duration. This information will be formatted in a spreadsheet and summarized on a monthly/annual basis.

APPENDIX A – AIR MONITORING PLAN

A.1.1 Introduction

This Air Sampling Plan presents the approach that will be followed to document worker exposures and the effectiveness of engineering controls in limiting off-Site migration of particulate matter during Site-wide remediation activities at the former DuPont Works Site in DuPont, Washington. Two types of sampling are specified in this plan, personal work space sampling and Site boundary (PM10) sampling. Work space sampling will be conducted for the entire duration of the excavation work associated with remediation activities, to ensure that workers performing remediation activities are not exposed to elevated levels of arsenic and lead. In addition, while excavation work is taking place, water truck(s) will be used to minimize dust generation by spraying roadways and work areas with water. Site boundary (PM10) sampling will be done whenever excavation takes place within 500 feet of the south or east Site boundaries.

The purpose of this plan is to provide some guidelines for when air monitoring should be conducted. Air monitoring may be appropriate at more frequent intervals than indicated in this plan depending on Site-specific factors. Workers/Managers should use their professional judgment/common sense to adjust the sampling frequency so that it is appropriate for the site-specific situation.

During the Site-wide remediation at the former DuPont Works Site, DuPont, WA, large areas of arsenic and lead contaminated soil will be excavated. Workers may be exposed to lead and arsenic in the air that results from activities that generate airborne particulates. Extensive historical soil sampling indicated that the highest levels of arsenic and lead in Site soil were approaching 1,000 mg/kg and 10,000 mg/kg, respectively. Although these hot spot areas were removed during previous interim actions at the Site, it is possible that isolated high areas of contamination still remain.

The results of this air sampling program will be compiled and organized in a notebook at the Site field office using the forms (See Tables A-1, A-2, and A-3) so that all Site workers have access to the results. In addition, the results of the monitoring should be discussed at the morning daily health and safety meetings.

A.1.2 Section 2 – General Design Specifications

The objectives of the air sampling program are to:

- Quantify the level of exposure of workers to arsenic and lead in airborne dust;
- Quantify the amount of respirable particulate (i.e., PM_{10}) that may be transported into off-Site areas during excavation activities;
- Quantify the amount of arsenic and lead present in the PM_{10} samples;

- Compare the amount of arsenic and lead to appropriate health-based standards for both workers and off-site receptors.

The sampling approach for worker exposure monitoring and PM_{10} transport monitoring are described below.

A.1.3 Sampling Approach

The sampling plans, including the type and number of samples and the proposed locations for sampling, are described below.

A.1.4 Worker Exposure Monitoring

The procedures used for monitoring worker exposures will consist of collection of personal dust samples for analysis of arsenic and lead, and real-time measurement of airborne respirable particulate concentrations.

A.1.5 Personal Dust Samples

Personal air samples should be collected from those workers expected to receive the highest dust exposure (e.g., those working adjacent to an excavator). These data will be used to determine whether or not airborne arsenic and lead concentrations are below the Permissible Exposure Limit (PEL).

Personal air samples should be taken in the breathing zone of workers on the first day of the work week, during every week of excavation activities. It is recommended that one or two employees who are expected to receive the highest exposure be monitored. Samples will be collected to reflect an eight-hour exposure, and will be analyzed for both arsenic and lead.

A.1.6 Real-Time Air Monitoring

Realtime air monitoring should be conducted using a miniram (pDR-1000) in order to determine whether or not respirable particulate levels in the air are sufficiently low, so that the PEL for arsenic and lead will not be exceeded. The miniram should be used at the beginning the first week of field activities and the frequency of sampling should be determined based on the readings, changes in work patterns, or changes in soil conditions that potentially result in increased dust emissions.

Based on historical soil sampling results, the miniram concentration that would result in exposure to lead at the PEL is 5.0 mg/m^3. This assumes a soil concentration of 10,000 mg/kg lead, which is slightly higher than the maximum measured soil concentration known to be present on-Site. This level will also be protective for exposure to arsenic. To provide an additional margin of safety, it is recommended that continued measurements above 2.5 mg/m^3 result in Personal Protective Equipment (PPE) upgrade to Level C. This is the air concentration level that corresponds to one half of the PEL.

Monitoring should be conducted during heavy equipment operation (e.g., excavation of in-place soils). Readings should be taken at least every 15 minutes. If readings taken during the first day do not exceed 2.5 mg/m^3, sampling frequency can be reduced to sampling once every 15 minutes when the visible dust concentrations indicate that it is warranted.

A.1.7 PM10 Transport Monitoring

PM_{10} sampling will be performed to document the effectiveness of engineering controls in limiting off-Site migration of particulate during on-Site remediation work. Two PM_{10} samples will be collected each day. Samples will be collected on a 24-hour basis. At the start of the work shift in the morning, the PM_{10} samplers will be set up for the 24-hour day (the previous day's sample will be capped and sent for analysis).

The sequencing of excavation and prevailing wind direction will determine the specific sample locations. In general, the samplers will be located against the southwest boundary fence, which is the area on Site that is directly adjacent to off-Site development. PM_{10} monitoring will be conducted during excavation activities in Cleanup units 3, 4, and 5, because these are the only Units that are directly adjacent to off-Site development. The total excavation time in these units will be approximately three months (i.e. 90 days), which will result in a total of 180 (i.e., 90 x 2) samples.

All samples will be analyzed for PM_{10}, arsenic, and lead. To ensure that airborne particulates generated during remediation activities do not pose a threat to the general population who might work or live adjacent to the Site, measured concentrations of PM_{10} (particles with diameter of 10 micrometers or less, that are able to penetrate into lungs), arsenic, and lead will be compared to health-based concentrations. If PM_{10} concentrations approach regulatory levels of concern, engineering controls such as soil wetting will be increased to reduce particulate generation.

APPENDIX B – WASHINGTON STATE WATER WELL CONSTRUCTION ACT

WAC 173-160-400 What are the minimum standards for resource protection wells and geotechnical soil borings? The following minimum standards will apply to all resource protection wells and geotechnical soil borings constructed in the state of Washington. It is the responsibility of the resource protection well operator, resource protection well contractor, and the property owner to take whatever measures are necessary to guard against waste and contamination of the ground water resource.

(1) It will be necessary in some cases to construct resource protection wells and geotechnical soil borings with additional requirements beyond the minimum standards.

(2) Nothing in this section limits the department's authority to approve comparable alternative specifications for construction as technology in the industry is developed, or new methods of construction become known to the department.

WAC 173-160-420 What are the general construction requirements for resource protection wells? (1) No resource protection well or soil boring excavation may be used for domestic, industrial, municipal, commercial, or agricultural purposes.

(2) No resource protection well or soil boring excavation may interconnect aquifers.

(3) Nested resource protection wells are prohibited.

(4) Cuttings, development water, and other investigation derived waste from resource protection well construction or geotechnical soil borings will be managed in a manner consistent with the intent and purposes of the Water Pollution Control Act, chapter 90.48 RCW, the Hazardous Waste Management Act, chapter 70.105 RCW, and implementing regulations.

(5) Well tagging:

(a) It will be the drillers' responsibility to place a well identification tag with a unique identification number on every resource protection well that is constructed or altered. Uncased geotechnical soil borings are exempt from the tagging requirements of this chapter.

(i) The alpha-numeric number will be recorded on the drilling report in the space provided.

(ii) The drillers will remove the well identification tag on all resource protection wells they decommission and will attach the tag to the decommissioning well report.

(b) It will be the well owners' responsibility to place a well identification tag with a unique identification number on every resource protection well they own and which was completed prior to the effective date of this regulation.

(i) Upon request, the department will furnish the well owner with a well tag and tagging instructions.

(ii) The well owners will tag their well(s) and submit a completed tagging report to the department.

(c) The well tag will be permanently attached to the outer well casing and be visible above land surface for all wells which have been completed above land surface. For wells completed below land surface, the well tag will be attached to the well casing or to any permanent and protected portion of the vault.

(d) All well identification tags will be supplied by the department.

(e) It is unlawful for a person to tamper with or remove a well identification tag except during well alteration.

(6) All resource protection wells will be sealed in accordance with this chapter regardless of

the method of installation. Except, resource protection wells that are properly decommissioned prior to the removal of any drilling equipment from the well location are exempted from the surface sealing requirements of this chapter. Provided the decommissioning process includes the removal of any conduit, tubing, probe, or other items inserted into the ground.

(7) All geotechnical soil borings will be decommissioned under the terms of this chapter.

(8) Except as provided in RCW 18.104.180, all construction, alteration, reconstruction, and decommissioning of resource protection wells and geotechnical soil borings will be done by an individual licensed under the provisions of chapter 173-162 WAC.

(9) A notice of intent to construct or decommission a resource protection well and a geotechnical soil boring will be filed with the department a minimum of seventy-two hours prior to initiating construction or decommissioning of the well(s) or boring(s). A fee must accompany each notice of intent to construct a resource protection well. The fee for constructing, altering, or reconstructing each resource protection well is forty dollars. Geotechnical soil borings are **EXEMPT** from all fees. Under some circumstances, it may be necessary to construct more resource protection wells or geotechnical soil borings than originally anticipated. When additional resource protection wells are constructed on a site for which a notice of intent and fee were submitted, a second notice and fee will be submitted within twenty-four hours after all wells have been completed or as soon as the final number of wells to be constructed is determined, whichever is sooner. When additional geotechnical soil borings are needed, the borings may be completed. A follow-up notice of intent will be submitted to the department within twenty-four hours after all borings are constructed. Notification to construct multiple wells or geotechnical soil borings within the same quarter/quarter section, township, and range may be submitted on one notice form. A fee of forty dollars per well must be attached to each notice. Example: Six resource protection wells identified on one notice of intent would be submitted along with a two hundred forty dollar fee.

(10) Resource protection well and geotechnical soil boring drilling reports will be completed.

(a) All well contractors are required to submit a complete report on the construction, alteration, or decommissioning of all resource protection wells and geotechnical soil borings they construct. Reports must be submitted to the department within thirty days after completion of construction, alteration, or decommissioning.

(b) This applies to all resource protection wells and geotechnical soil borings.

(c) The resource protection well and geotechnical soil boring report must be made on a form provided by the department, or a reasonable facsimile of the form, as approved by the department.

(d) Where applicable the report will include the following information:

(i) Owner's name; operator/trainee name; operator/trainee license number; contractor registration number, drilling company name;

(ii) Tax parcel number;

(iii) Well location address;

(iv) Location of the well to at least 1/4, 1/4 section or smallest legal subdivision;

(v) Unique well identification tag number;

(vi) Construction date;

(vii) Start notification number;

(viii) Intended use of well;

(ix) The well depth, diameter, and general specifications of each well;

(x) Total depth of casing;

(xi) Well head elevation;

(xii) Drilling method;

(xiii) Seal material, seal location and type of placement used;

(xiv) Filter pack location; filter pack material used;

(xv) The thickness and character of each bed, stratum or formation penetrated by each well including identification of each water bearing zone;

(xvi) Casing gauge, diameter, stickup, type of material, and length, also of each screened interval or perforated zone in the casing;

(xvii) The depth to the static water level, as measured below the land surface; and

(xviii) Such additional factual information as may be required by the department.

(e) The well report must show the license number and signature of the person who constructed the well. If this is an unlicensed person, exempted under RCW 18.104.180(2), the report will show the license number and signature of the licensed individual who witnessed the drilling. Resource protection well reports for wells constructed by trainees will have the signatures and license numbers of both the trainee and licensed operator.

What are the surface protection requirements?

(11) All resource protection wells will be capped and protected using one of the following methods:

(a) If the well is cased with metal and completed above the ground surface, you must attach a watertight cap with a lock to the top of the casing.

(b) If the well is not cased with metal and completed above the land surface, you must install a protective metal casing over and around the well. The protective casing will extend at least six inches above the top of the well casing and be cemented at least two feet into the ground. A cap with lock will be attached to the top of the protective casing.

(12) You will protect the well(s) completed above ground from damage by:

(a) Cementing three metal posts, at least three inches in diameter, in a triangular array around the casing and at least two feet from it. Each post will extend at least three feet above and below the land surface.

(b) Installilng a reinforced concrete pad to protect against and prevent frost heave. If installed, the concrete pad will extend to a depth equal to anticipated frost depth. When a concrete pad is used, the well seal may be part of the concrete pad.

(13) If the well is completed below land surface, a watertight cap with a lock will be attached to the top of the well casing. A metal monument or equivalent will be installed over and around the well. The monument will serve as a protective cover and be installed level with the land surface and be equipped with a waterproof seal to prevent the inflow of any water or contaminants. Drains will be provided, when feasible, to keep water out of the well and below the well cap. The cover must be designed to withstand the maximum expected loading.

(14) The protective measures may be waived or modified upon written approval from the department (a variance).

(15) If the well is damaged, the well protection measures and casing will be repaired to meet the requirements of this chapter. If the well is damaged beyond repair, it will be decommissioned in accordance with WAC 173-160-460.

WAC 173-160-430 What are the minimum casing standards? The casing may not affect or interfere with the chemical, physical, radiological, or biological constituents of interest. All

resource protection well casing will conform to ASTM Standards, or at least 304 or 316 stainless steel, PTFE, or Schedule 40 PVC casing.

WAC 173-160-440 What are the equipment cleaning standards? (1) When drilling in known or potential areas of contamination, steam clean the drill rig derrick and all drilling equipment on site before and after well construction. If the equipment is used to drill in radioactive areas, you must develop a decontamination plan and the department must approve that plan prior to the equipment being removed from the drill site.

(2) All well construction materials to include casing, screen(s), and filter pack material must be free of contaminants prior to installation.

WAC 173-160-450 What are the well sealing requirements? (1) All resource protection wells constructed will have a continuous seal, which seals the annular space between the bore hole and the permanent casing. The seal will be constructed to prevent interconnection of separate aquifers penetrated by the well, and will provide casing stability. The seal will have a minimum diameter of four inches larger than the nominal size of the permanent casing, and will extend from land surface to the top of the filter pack. See Figure 7.

(2) After the permanent casing has been set in final position, the filter pack (optional) and sealing material will be placed in the open bore hole annular space that must be a minimum of four inches greater in diameter than the nominal size of the permanent casing. After installing the filter pack (optional) a layer of bentonite will be placed on top of the filter pack to maintain separation between the seal material and the screened interval. Insure that placement will not disturb the filter pack. The remaining annular space will be filled to land surface in a continuous operation with bentonite, neat cement, or cement grout. If a cement/bentonite slurry is used as the sealant, it will be installed with a tremmie tube and pumped from the top of the bentonite plug (above the filter pack) to land surface. Use only potable water to hydrate the mixture.

(3) The completed annular space will fully surround the permanent casing, be evenly distributed, free of voids, and extend from the permanent casing to undisturbed or recompacted soil.

(4) All sealing materials used will conform to one of the following minimum requirements:

(a) **Bentonite sealants:**

(i) Bentonite used to prepare slurries for sealing, or decommissioning will be specifically designed for this purpose. At no time will grout slurry contain materials that are toxic, polluting, develop odor or color changes, or serve as a micro-bacterial nutrient. All bentonite slurries will be prepared and installed according to the manufacturer's instructions. All additives must be certified by a recognized certification authority such as NSF. Active solids content (bentonite) will be twenty percent by weight or greater in all bentonite slurries.

(ii) Unhydrated bentonite--pelletized, granulated, powder, or chip bentonite may be used in the construction of seals or in decommissioning of resource protection wells. The bentonite material will be specifically designed for sealing or decommissioning and be within the industry tolerances for dry western sodium bentonite. Polymer additives must be designed and manufactured to meet industry standards to be nondegrading and must not act as a medium which will support or promote the growth of micro-organisms. All unhydrated bentonite used for sealing or decommissioning must be free of organic polymers. Placement of bentonite will conform to the manufacturer's specifications and result in a seal free of voids or bridges.

(b) **Cement sealants:**

(i) Neat cement consists of either portland cement types I, II, III, or high-alumina cement mixed with not more than six gallons of potable water per sack of cement (ninety-four pounds per sack).

(ii) Neat cement grout consists of neat cement with up to five percent bentonite clay added, by dry weight of the bentonite. Bentonite is to be added to improve flow qualities and compensate for shrinkage.

(iii) Concrete sealants consist of clean, hard and durable aggregate with not less than five sacks (ninety-four pounds per sack) of portland cement per cubic yard of concrete sealant.

(A) The maximum diameter of aggregate particles may not exceed 1 1/2 inches, but in any case may not exceed 1/5 the minimum width of the casing thickness.

(B) The ratio of coarse aggregate to fine aggregate (passing No. 4 U.S. Standard Sieve) must be approximately 1-1/2 to 1 by volume, but in any case, may not exceed 2 to 1 nor be less than 1 to 2.

(iv) Expanding agents, such as aluminum powder, may be used at a rate not exceeding 0.075 ounce (1 level teaspoon) per sack (ninety-four pounds per sack) of dry cement. The powder may not contain polishing agents. High-alumina cement and portland cement of any type must not be mixed together.

(5) This section may not preclude the use of new sealant materials which have been approved by the technical advisory group.

WAC 173-160-460 What is the decommissioning process for resource protection wells? (1) Resource protection wells that were not constructed in accordance with these regulations, or for which a drilling report required under this section is missing, will be decommissioned in one of the following ways:

(a) Perforate the casing from the bottom to land surface and pressure grout the casing.

(i) Perforations will be at least four equidistant cuts per row, and one row per foot. Each cut will be at least one and one-half inches long.

(ii) Apply enough pressure to force the sealing material through the perforations, filling any voids on the outside of the casing.

(iii) The remainder of the casing will be filled with cement grout, neat cement, or bentonite slurry.

(b) Withdraw the casing and fill the bore hole with cement grout, neat cement, or bentonite as the casing is being withdrawn.

(2) If it can be verified through a field examination and review of the drilling report that the resource protection well was constructed in accordance with these regulations, it will be decommissioned by:

(a) Filling the casing from bottom to land surface with bentonite, cement grout, or neat cement; and

(b) Placing a cap on the casing.

INTERIM SOURCE REMOVAL MEMORANDUM
AREA 8 PIPELINE AND FORMER ABOVE-GROUND STORAGE TANKS
FORMER DUPONT WORKS SITE
DUPONT, WASHINGTON

Dupont Environmental Remediation Services (DERS) conducted interim source removal activities along the former Bunker-C pipeline and in the former above-ground storage tanks (AST) area. The pipeline carried Bunker-C fuel to the ASTs and to the upper powerhouse. Olympus Environmental Services provided excavation services during this work. The activities at the site are detailed in DERS' **Source Removal Work Plan - Area 8**, dated September 16, 1991.

Hart Crowser provided technical assistance and field oversight to DERS during the interim source removal activities. We conducted soil verification sampling and analysis to characterize the subgrades after source removal and soil designation sampling and analysis to characterize Area 8 stockpiles relative to Washington State solid waste and dangerous waste regulations. A detailed discussion of Hart Crowser's scope of work is presented in the **Oversight Work Plan - Area 8**, dated October 29, 1991.

Summary of Activities

DERS removed approximately 29,100 cubic yards (excavated) of soils from the pipeline and former AST locations between January 1992 and August 1993. Of this amount approximately 18,000 cubic yards have been or will be sent to Woodworth & Company in Tacoma, Washington, for recycling and the remaining "clean soil" will be used as site backfill material following approval by the Washington State Department of Ecology (Ecology). The Bunker-C pipeline sections along the level portion of the pipeline were removed, steam cleaned, and disposed of off site at Chemical Waste Management's hazardous waste landfill in Arlington, Oregon. The lead packing in the pipe joints was removed and is currently awaiting disposal. In June 1992, residual product from the sloped section of the pipeline was drained into 55-gallon drums. The pipeline was cleaned and grout-filled for abandonment in place. A total of forty 55-gallon drums of residual Bunker C product and cleaning waters were disposed of by incineration at the OSCO facility in Henderson, Colorado.

Hart Crowser provided field documentation of the daily activities in the form of daily field reports.

Summary of Analytical Results

Prior to source removal, we collected soil characterization samples from 11 test pits, 3 borings, and 4 surface locations along the pipeline and AST area to characterize the extent of petroleum-impacted soils. The samples were analyzed for total petroleum by method 418.1 and selected samples were tested for PAHs, total lead, volatiles (methods 8015 and 8240), and semivolatiles. Characterization sample locations are presented on Figure 1. Chemical analytical results for the initial soil characterization are presented in Tables 1, 2, and 3.

Following interim source removal excavation activities, we collected 24 verification soil samples along the former pipeline and 24 verification soil samples from the former AST location. The pipeline and AST sample locations are shown on Figures 2 and 3, respectively. Pipeline and AST analytical data for the verification soil samples are presented in Tables 4 and 5, respectively. The verification soil samples were analyzed for TPH by Method 418.1 at either the Hart Crowser Chemistry Laboratory or Analytical Technologies, Inc. Selected soil samples were analyzed for cPAH based on an evaluation of TPH results.

Nine verification soil samples were collected along the Bunker C pipeline to evaluate the potential leachability of soils with elevated TPH concentrations. Selected samples were analyzed for toxicity characteristic leaching procedure (TCLP) cPAH and TCLP TPH. The TCLP analytical data are presented in Table 6. TCLP verification sample locations are presented on Figures 2 and 3.

Forty-seven soil samples were collected from Area 8 soil stockpiles for designation analysis. Soil designation analytical results are presented in Tables 7, 8, 9, and 10. Analytical results for six samples (8-DS-26 through 8-DS-29, 8-DS-31, and 8-DS-44) did not exceed 200 mg/kg TPH. Stockpiles represented by these six samples remain on site. The other stockpiles whose analytical results exceeded 200 mg/kg TPH are currently being shipped off site to Woodward and Company for recycling.

Considerations

Analysis of the data from the final verification soil sampling indicates that the pipeline and AST areas have met the 570 mg/kg TPH concentration that correlates to 1 ppm cPAH at the 90th percentile confidence interval, for soils above depths of 15 feet, and the 11,000 mg/kg non-leachable TPH concentration for soils below depths of 15 feet, indicating that no further interim source removal action is required.

The remaining site soil stockpiles from Area 8, which based on 6 samples are below 200 mg/kg, are being considered for use as clean backfill material, following approval by Ecology.

Notes:

U	Not detected at indicated detection limit.
J	Estimated value.
NA	Not analyzed.
ND	Not detected.
(a)	Total represents the sum of detected values only.
(b)	Total includes one-half the detection limit of non-detected compounds.
(c)	Only those compounds detected are listed.
(d)	Pyrene and chrysene were detected in semivolatile (8270) analysis but were not detected in PAH (8310) analysis. This was due to the interference of high hydrocarbon concentrations in the sample. The hydrocarbon interference resulted in the target peaks shift out of the retention time windows. However, the mass spectrometer can still identify the peaks. Therefore, the GC/MS results should be used. (PAHs are analyzed by HPLC method and semivolatiles are analyzed by GC/MS method.)
(e)	Sample locations excavated during subsequent source removal.

NA	Not analyzed.
ND	Not detected.
(a)	Total represents the sum of detected values only.
(b)	Total includes one-half the detection limit of non-detected compounds.
(c)	Only those compounds detected are listed.
(d)	Pyrene and chrysene were detected in semivolatile (8270) analysis but were not detected in PAH (8310) analysis. This was due to the interference of high hydrocarbon concentrations in the sample. The hydrocarbon interference resulted in the target peaks shift out of the retention time windows. However, the mass spectrometer can still identify the peaks. Therefore, the GC/MS results should be used. (PAHs are analyzed by HPLC method and semivolatiles are analyzed by GC/MS method.)
(e)	Sample locations excavated during subsequent source removal.

1.0 Introduction

This report describes the activities that were undertaken to excavate soils at the former DuPont Works Site in order to prepare six different areas for sand stockpiles. This program was done as an interim action as allowed under the July 1991 Consent Decree signed by the Weyerhaeuser Company (Weyerhaeuser), E.I. duPont de Nemours and Company (DuPont) and the Washington State Department of Ecology (Ecology). The program was initiated in October of 1999 and completed in December of 1999.

A key component of the overall plan for the former DuPont Works Site involves excavating contaminated soils and placing them in specific areas (i.e., Placement Areas) within the future golf course boundary. These soils will be covered with an engineered cap. The sand will be used as topfill for the cap. The volume of sand needed for the project was available from the Glacier Northwest Plant that is adjacent to the Site.

The objective of the sand laydown program was to remove surface soil from six areas on the site so that sand could be stockpiled in these areas and not moved again until placed on the golf course cap. These six areas were located so that they are directly adjacent to the areas where the sand will be used. Figure 1 presents the location of the Sand Laydown Areas (SLAs) and identifies the Placement Areas where the excavated soil was placed. Table 1 identifies the SLAs, excavation depths, the volume of soil that was excavated, and where the soil was placed. A summary of the field activities is presented in Appendix A.

Table 1 – Sand Laydown Area Information

Sand Laydown Area	Placement Area for Soil	Excavation Area (feet)	Average Excavation Depth (feet)	Volume Excavated (Cubic Yards)
1	PA-07	83,022	3	9,225
2	PA-07	57,326	2.5	5,308
3	PA-02	78,475	1.5	4,360
4	PA-03	42,163	1.5	2,342
5	PA-05	76,137	1.5	4,230
6	PA-06	99,538	1.5	5,530
			TOTAL	30,995

2.0 Sand Laydown Area Analytical Results

Soil samples were collected within each SLA excavation to demonstrate statistical compliance with the Model Toxic Control Act (MTCA) three-fold criteria. A 50 foot grid was proposed to and accepted by Ecology as appropriate to demonstrate that each excavated area was in compliance with the MTCA three-fold statistical compliance criteria. The starting point for the excavation grid was related to the Site-wide 150-foot sample grid. Figures 2 through 7 present the extent of the excavations, as well as, the post-excavation arsenic and lead confirmation sample results. The sampling results are presented in Appendix C.

The data for each of the six excavations were compared to screening levels of 60 mg/kg for arsenic and 118 mg/kg for lead. Samples inside each excavation were grouped together to demonstrate that the vertical extent of each of the excavations are in compliance with the arsenic and lead screening levels. The compliance statistics are in Table 2.

3.0 Conclusions

The findings and conclusions of this program are presented below:

1. In general, post-excavation sample concentrations were near or below background levels for both lead and arsenic. Exceptions were areas where there were visible debris or foundations where concentrations of lead were slightly elevated due to its association with some buildings at the site.

2. No sand was stockpiled in SLA areas where there were visible debris (SLA#1) or foundations (SLA#1, SLA#6) (See Figures 2 and 7).

3. Based on the evaluation of the pre-existing and collected data, this program met its goals. When debris and foundation samples are excluded, all six of the excavations are in compliance with the MTCA three-fold criteria.

Lead	48	42	120	19	25	10	26	Unknown	30	118	1	2.1%

Note:

[(a)]The MTCA UCL was determined based on the following decision rules:

1. Use the log 95% UCL if the data distribution is lognormal.
2. Use the 95% UCL if the data distribution is normal.
3. Use either the log 95% UCL, arithmetic 95% UCL, or the approximate one-sided upper confidence limit on the mean if the data distribution is unknown.
4. Use the maximum detected value if the maximum detected value is greater than the appropriate UCL statistic.

The following decision rules were followed for duplicate samples in order to develop a dataset for statistical analysis:

1. If all of the results were detected values, then the two values were averaged.
2. If all the results were non-detects then use the highest non-detected value.
3. If there was a mixture of detects and non-detects, then take the highest detected value.
4. The resulting value was assigned to the primary sample ID and the other duplicate samples were excluded from the data tables and figures.

Appendix A – Summary of Field Activities

A.1 Project Management/Resources

This program was performed under the direction of the Site Management Team (ST). Each of the ST members and their responsibilities for this project are described below.

- Jeff King of West Shore Corporation, NW (WSNW), performed day-to-day oversight of the project activities.
- URS performed the confirmation sampling, and Sound Analytical Services, Inc. was the Project laboratory.
- Active Construction (ACTIVE) of Gig Harbor, Washington was the remediation contractor.
- PIONEER Technologies Corporation (PTC) managed the analytical data and developed the figures.
- The Sand Laydown Program Interim Action Report was created collectively by PTC, WSNW, and URS.

A.2 Cultural and Archaeological Management

The program followed the criteria listed in the Project's Cultural and Archaeological Management Plan. This plan, which is based upon cooperative agreements established between Weyerhaeuser, the Nisqually Tribe, and the Washington State Office of Archaeology and Historic Preservation (OAHP), identifies the terms for compliance for Site construction activities. As a result of this plan, the following activities took place:

- All individuals involved in this program were trained by the Project's Archaeology Consultant, Western Heritage, on the identification of items of cultural or historic significance prior to the start of field work.
- Western Heritage was present on the site during the excavation and site preparation phases of the program.

A report describing the findings of, and any observations made, during this program will be issued to Ecology and OAHP within the next month.

A.3 Site Preparation

Phase One of this program included locating and flagging the SLA locations and clearing and grubbing each work area. ESM Incorporated (ESM) of Federal Way, WA located and flagged the location of each area. A field check of the locations was conducted and the boundaries of the work areas were flagged by PTC and WSNW. Olympia Timber cleared and grubbed any trees and vegetation within 50 feet of each location and any other areas needed to safely complete the project.

A.4 Field Construction Activities

The excavation of the areas was initiated after the site preparation activities were completed. In general the process consisted of the following steps.

1. ACTIVE initially excavated to the perimeter of the staked area to depth of 1.5 foot except for SLA#1 where debris was encountered and the excavation activities continued to approximately 3 feet.
2. SLA#2 was excavated to 2.5 feet in an attempt to excavate to a gravel layer but a gravel layer was not reached.
3. Once an area was excavated ACTIVE moved on to the next excavation. Decisions for further excavation were made once initial laboratory results were available.

A.5 Sampling Confirmation Activities

This SLA Program was performed in accordance with the Hot Spot Removal Program Work Plan which summarizes characterization procedures and was prepared before field activities were initiated[1]. This Work Plan was generally consistent with the sampling and analytical activities specified in the 1992 Management Plan[2]. URS prepared a site-specific health and safety plan for use by on-site URS personnel.

Sampling began once ACTIVE had completed 2 days of work. Samples were collected in accordance with the Hot Spot Removal Program Work Plan. Soil samples were collected by placing soil into clean stainless steel bowls, mixing the soil with a clean stainless steel spoon to homogenize the sample, and then placing the soil into 4-ounce glass jars. The sampling equipment was decontaminated according to the Work Plan immediately prior to collecting each sample. Samples were held under chain-of-custody procedures at all times. The samples were delivered to the Project laboratory on a 3-day turn around basis.

Sample locations were surveyed by ESM based on the site-wide confirmation sampling grid. The 150 foot grid was further refined so that samples were collected on 50 foot centers for demonstration purposes. Each sample was discrete. Preliminary sample results were issued to the Project Team and decisions for further excavation were made based upon these results.

A.6 Secondary Excavations

Because of the tight schedule, a field call was made in SLA#5 in order to ensure that arsenic and lead concentrations were not elevated. One area (i.e., sample SA5-88-44, arsenic = 45, and lead = 100) was excavated an additional 1 foot.

A.7 Sand Hauling

Once confirmation samples were obtained, and evaluated sand was hauled by ACTIVE from the Glacier Northwest Plant adjacent to the Site, and stockpiled. All travel was done using pre-existing roads. At no time was sand hauled on public streets.

Appendix B – Laboratory Analytical Data Validation Results

B.1 Summary

The data reviewed are acceptable for use based on a majority of acceptable quality control data. The data meet criteria specified in the 1992 Hart Crowser Management Plan[3]. The data may be used to assess analyte concentrations with the stated qualifications.

B.2 Introduction

This section presents a quality control (QC) review of data generated from collection and analysis of soil samples from the former DuPont Works Site in Dupont, Washington, from September 10, 1999 through July 17, 2000. The SLA data were collected during this period and therefore, all of the Data Validation information is presented in the Hot Spot Interim Action Report (PIONEER et al., Oct. 4, 2000). Samples were submitted to Sound Analytical Services, Inc. for analysis. This review includes evaluation of the following:

- Laboratory report and reporting of required analyses
- Chain of custody and holding times
- Method blanks
- Matrix spike / blank spikes (MS / BS)
- Laboratory duplicates
- Field duplicates
- Reporting limits

The data quality review was conducted using guidance from the following documents:

- National Functional Guidelines for Inorganic Data Review, EPA, February 1994.
- Remedial Investigation/Feasibility Study, Former Dupont Works Site Management Plan, Hart Crowser, January 1992.

Criteria used to assess the data are found in Section 5 of the Management Plan. The analytical data has been compared to the Management Plan limits. The samples were analyzed for the following chemicals, using the noted analytical methods.

Arsenic	EPA 6010
Lead	EPA 6010

B.3 Sample Data Groups

The sample data groups identified in Table B-1 were included in this data review.

[3] HartCrowser. January 17, 1992. Management Plan. Remedial Investigation/Feasibility Study Former DuPont Works Site, DuPont, WA.

Table B-1 – Sample Data Groups Included in the Data Review

Sound Analytical Services Data Group Number	Date Sampled
84778	12 Oct 99
84800	13 Oct 99
84832	14 Oct 99
84863	15 Oct 99
84898	18 Oct 99

B.4 Laboratory Report and Reporting of Required Analyses

The laboratory report was complete; all QC results were included. The project scope of work stated that URS would provide industry-accepted evaluation of data quality and documentation of sample acquisition and custody. Comprehensive data validation was not requested for this sampling event. The reports provide all necessary information to complete this review. All analytical methods were reported as requested.

B.5 Chain of Custody and Holding Times

Samples were maintained under chain of custody until arrival at the laboratory. Samples were preserved and cooled until arrival at the laboratory. Sample bottles were in good condition. The samples were extracted and analyzed within the 6 month holding time. Holding times were within specifications of the Management Plan.

B.6 Method and Field Blanks

Method blanks were used to determine if samples were contaminated through laboratory procedures or equipment. The laboratory method blanks were free of target analytes. The QC frequency requirement of one laboratory blank per analytical batch was met. No data require qualification based on field rinse blank contamination.

B.7 Matrix Spikes/Blank Spikes

- Matrix spike (MS) analyses were used to assess matrix effects with respect to the analytical data. The QC frequency requirement of one MS and one blank spike (BS) per analytical batch or one MS and one BS per 20 samples, was met. The MS and BS results were compared to evaluate the accuracy of laboratory procedures. The spike recoveries ranged from 76 to 125 percent and were within the control limits.

B.8 Laboratory Duplicates

The relative percent differences (RPDs) ranged from 0 to 34 percent and were within the control limits established by the laboratory. Therefore, no data were qualified due to laboratory duplicate RPDs.

B.9 Field Duplicates

- Field duplicate samples were used to assess sampling precision and representativeness. The QC frequency requirement of one field duplicate for 5 percent of the total samples, or one field duplicate per day at a minimum, specified in the Management Plan, was met. Forty-two sets of field duplicate samples were collected. Table B-2 presents the RPD of detected compounds that were calculated for the duplicate pairs. The RPDs were acceptable.

Table B-2 – RPD of Detected Compounds

SAMPLE ID & DUPLICATE ID	ANALYTE	PRIMARY RESULT (µg/L)	DUPLICATE RESULT (µg/L)	RPD %
SA5-8944/SA5-8940	Arsenic	11	12	9
	Lead	14	17	19

B.10 Reporting Limits

To ensure the level of analytical reporting sensitivity meets project goals, reporting limits were reviewed. Reported results are acceptable.

1 Introduction

Stockpiles of soil containing high levels of arsenic and lead were created as part of the 2000 hot spot removal program and other previous interim actions. The level of arsenic and lead in these stockpiles is too high to permit on-site disposal. Therefore, to limit the amount of soil requiring off-site disposal, a soil screening plant was assembled where the stockpile material could be washed and separated into five different fractions. The five separate fractions were individually sampled to determine their designation for either off-site disposal or placement on site.

This report presents a description of the screening plant, screening process, and results of the confirmatory sampling conducted to determine the appropriate disposal option for each stockpile fraction.

2 Background

As part of an interim removal action, a soil screening plant was installed on the site to separate out contaminated stockpile fractions for off-site disposal. The screening plant was assembled during March, April, and May of 2001 by Materials Processing Inc. (MPI) of Issaquah, Washington. Adjacent to the screening plant, a two-acre sloped asphalt drying pad was created to contain the fine material fraction (i.e., the fines). The drying pad also has a sump that collected the water that ran off from the fines. The water from the sump was pumped back into the screening plant process. The plant was tested with clean dirt and the pump rate was adjusted to ensure that the 50,000-gallon system was in balance.

3 Summary of Activities

The activities completed in the stockpile screening program and water filtration programs are described below.

3.1 Screening Process

Soil was loaded into the screening plant conveyer where the material went over the 3 inch vibrating screen with water spray bars. Cobbles greater than 3 inches and other material such as plastic and pieces of wood were conveyed to a pile. Material that went through the upper screen then fell to the lower 3 inch to ¼ inch vibrating screen. The oversized fraction (i.e., gravels) then went to a twin screw wash and were conveyed to a separate pile. The less than ¼ inch material went to twin cyclones in a water slurry. The material down to 200 mesh (i.e., sand) was captured and placed in a separate pile. The humus organic matter that floated was captured and sent to a separate pile. The remaining material (i.e., fines less than 200 mesh) was then piped to a double cell clarifier. Flocculent and coagulent were added to facilitate settling out of the material. A drag chain moved the material to a chute where it was captured in a dump truck and placed in a gravel bermed cell on the drying pad. The water in the cell drained through the gravel berm and when the material was dry, it was stockpiled. Following screening, the fines were spread out on the drying pad and turned over regularly using a wide track tractor and a disc in order to decrease the water content. Figures 1 and 2 identify the different components of the screening plant.

The water collected in the sump was pumped to Baker tanks for storage future disposal. Prior to disposal, the tank water was filtered using a sand filter, a bag filter, and a 0.5 micron cartridge filter. The water was then be sampled for lead and arsenic. The water was either disposed of or re-filtered depending on the laboratory results.

3.2 Screening Plant Sampling Program

Samples were collected from each different fraction (i.e., cobbles, gravel, sand, humus, and fines) on a regular basis (e.g., generally once each hour) during screening plant operation. The plant operated on a 24-hour cycle, therefore samples were typically collected hourly (while the plant was running) from 12:00 p.m. one day until 12:00 p.m. the next day. The hourly samples were composited, and one sample from each fraction was delivered to Sound Analytical Services. The different fractions were labeled as follows:

Description	Size Fraction	Sample Name
Cobbles	Greater than 3 inches	SCPL-3PLUS-COB-
Gravel	3 inches to ¼ inch	SCPL-3 TO 1/4-
Sand	¼ inch to 200 mesh	SCPL-1/4 TO 200-
Humus	Organic matter	SCPL-HUMUS-
Fines	200 Mesh or less	SCPL-FINES-

3.3 Filtering of Residual Water

After the screening process was completed there was approximately 47,500 gallons of water remaining in the screening plant system. A three stage filtration system was obtained from Rain-for-Rent that included a packed sand filter, a bag filter, and a 0.5 micron canister type filter. Water from the screening plant was pumped through these filters in order to remove the particles. A water sample was collected every 500 gallons and composited so that there was one sample analyzed by the laboratory for every 2,500 gallons of filtered water. The filtered water was placed in a storage tank until the results were obtained from the laboratory.

4 Results

4.1 Screening Plant

The analytical results for each 24-hour batch from the screening plant are presented in Appendix A. In instances where the arsenic concentration exceeded 530 mg/kg or the lead concentration exceeded 4,100 mg/kg, the cobbles, gravel or sand fractions were run through the screening plant again, sampled, and stockpiled separately. The fractions that were rewashed are presented in Table 1. Fines where the concentration exceeded 530 mg/kg arsenic or 4,100 lead were stockpiled for drying. Screened material that was less than 530 mg/kg arsenic or 4,100 mg/kg lead were placed in Placement Area Number 6.

Table 1 – Fractions that Were Rewashed

Date	Sample ID	Analyte	Result (mg/kg)	Notes	Rewashed Results
6/18/01	SCPL-3 to 1/4-02	Arsenic	13	Rewashed 6/20 as SCPL-3 TO 1/4-02-2	3
6/18/01	SCPL-3 to 1/4-02	Lead	11,000	Rewashed 6/20 as SCPL-3 TO 1/4-02-2	25
6/26/01	SCPL-3 TO 1/4-07	Arsenic	7	Rewashed 6/28 as SCPL-3 TO 1/4-07-02	16
6/26/01	SCPL-3 TO 1/4-07	Lead	6,200	Rewashed 6/28 as SCPL-3 TO 1/4-07-02	31
7/9/01	SCPL 3 PLUS COB - 12	Arsenic	40	Rewashed 7/12 as SCPL3PLUSCOB-12-2	110
7/9/01	SCPL 3 PLUS COB - 12	Lead	12,000	Rewashed 7/12 as SCPL3PLUSCOB-12-2	2,700
7/23/01	SCPL3TO1/4-20	Arsenic	24	Rewashed on 7/25 as SCPL-3TO1/4-20-2	73
7/23/01	SCPL3TO1/4-20	Lead	18,000	Rewashed on 7/25 as SCPL-3TO1/4-20-2	250
7/24/01	SCPL 3 PLUS-COB-21	Arsenic	27	Rewashed on 7/30 as SCPL3PLUSCOB21-2	48
7/24/01	SCPL 3 PLUS-COB-21	Lead	100,000	Rewashed on 7/30 as SCPL3PLUSCOB21-2	860
7/24/01	SCPL 1/4-200-21	Arsenic	23	Rewashed on 7/26 as SCPL1/4-200-21-2	69[(a)]
7/24/01	SCPL 1/4-200-21	Lead	7,500	Rewashed on 7/26 as SCPL1/4-200-21-2	11,000[(a)]
7/25/01	SCPL3PLUS-COB-22	Arsenic	63	Rewashed on 7/30 as SCPL3PLUSCOB21-2	48
7/25/01	SCPL3PLUS-COB-22	Lead	5,400	Rewashed on 7/30 as SCPL3PLUSCOB21-2	860
7/31/01	SCPL1/4-200-25	Arsenic	28	Rewashed on 8/06 as SCPL 3 PLUSCOB-26-2	37
7/31/01	SCPL1/4-200-25	Lead	6,600	Rewashed on 8/06 as SCPL 3 PLUSCOB-26-2	1,200

[(a)]This fraction was re-washed a third time (i.e., sample SCPL1/4-200-21-3 is a Rewash of SCPL1/4-200-21-2 and SCPL1/4-200-22) and the results for arsenic and lead were 52 and 1,400, respectively.

4.2 Screening Plant Water

The analytical results for each 2,500-gallon batch of water from the screening plant are presented in Table 2. In instances where the arsenic concentration exceeded 50 ug/L or the lead concentration

exceeded 15 ug/L the water was pumped back to the storage tank and re-filtered (See Table 2 for details). Water with arsenic and lead concentrations that were less than the associated arsenic and lead drinking water levels was discharged to the ground.

Table 2 – Screening Plant Water Filtration Results

Date Sampled	Sample	Arsenic (ug/L)	Lead (ug/L)	Number of Gallons	Action	Comment
9/20/01	SP-Water-01	ND(10)	16	2,500	Pumped water back into the storage tank	
9/27/01	SP-Water-02	ND (10)	ND (10)	2,500	Discharged water to ground	
10/11/01	SP-Water-03	ND (10)	ND (10)	2,500	Discharged water to ground

12/5/01	SP-Water-18	ND (10)	ND (10)	2,500	Discharged water to ground	Replaced the 0.5 micron canister filters.
12/11/01	SP-Water-19	ND (10)	14.2	2,500	Discharged water to ground	Replaced the 0.5 micron canister filters.
12/11/01	SP-Water-20	ND (10)	ND (10)	2,500	Discharged water to ground	Replaced the 0.5 micron canister filters.
12/12/01	SP-Water-21	ND (3)	2.19	2,500	Discharged water to ground	Replaced the 0.5 micron canister filters.
12/12/01	SP-Water-22	ND (3)	2.12	2,500	Discharged water to ground	Replaced the 0.5 micron canister filters.
12/17/01	SP-Water-23	ND (10)	ND (10)	2,500	Discharged water to ground	Replaced the 0.5 micron canister filters.
12/17/01	SP-Water-24	ND (10)	11.7	2,500	Discharged water to ground	Replaced the 0.5 micron canister filters.

ND = Not detected
Drinking water standards for arsenic and lead are 50 and 15 ug/L, respectively.

5 Summary

Approximately 36,028 tons of arsenic and lead contaminated soil was processed through the screening plant. The plant was effective in separating the contaminated fines from the other fractions. After drying there was approximately 2,500 tons of arsenic and lead contaminated fines to be disposed of off-site. In addition, approximately 47,500 gallons of water was filtered to remove arsenic and lead. The filter cake and used filters will be disposed of off site.

1 Introduction

As of March 9, 2001 there were approximately 90,000 cubic yards of soil and debris stockpiled at the former DuPont Works Site (Site) that required further evaluation, testing, designation or disposal. These stockpiles were created as a result of interim source removal activities conducted between 1991 and 1995. In 2001 the Weyerhaeuser and DuPont Companies decided to conduct work to characterize, designate and either dispose of off-site or place these soils on-site. This report describes the work accomplished and the results of this program. All work conducted and the data collected during this program where done using the methodology described in the *Interim Source Removal Actions: On-site Stockpiles (March 9, 2001) Work Plan* that was approved by Ecology.

2 Background

One hundred and three stockpiles where included in this program. They were created as part of the following past interim source removal (ISR) work:

- 61 were created as part of the Interim Source Removal (ISR) effort to remove lead impacted debris and soil.
- 3 were created as part of ISR efforts to remove Dinitrotoluene (DNT) and Trinitrotoluene (TNT) impacted soils.
- 12 were created as part of the ISR effort to remove debris from the Area 5 Kettle.
- 2 were created as part of the ISR effort to remediate Area 40 foundations.
- 1 was created as part of the ISR effort to remediate Total Petroleum Hydrocarbons (TPH).
- 24 were created as part of other ISR efforts involving the removal of non-soil debris.

This program did not disturb in-place soil. Therefore, no archeological monitoring was conducted.

3 Summary of Activities

This program was accomplished in the following steps:

3.1 Stockpile Inventory

The Project's stockpile management plan was revisited and a site inventory was conducted to further refine the grouping of stockpiles. A map that identified all of the stockpile locations was developed to guide the field activities.

3.2 Evaluation of Data

Each stockpile was evaluated to determine if it had been properly characterized using the following process:

- Data for each stockpile was reviewed to determine the number of samples per cubic yard (CY) of material.
- When the number of data exceeded 1 sample per 500 CY the stockpile was considered to be adequately characterized and the data were evaluated.
- Designation of the stockpile was done on a pass/fail basis. If one sample exceeded the limit for a certain disposition option (see Section 3.3) the whole stockpile was designated for the more protective option.
- Stockpiles that did not meet the 1-sample-per-500-CY criterion where determined to be non-characterized and resampled.

3.3 Stockpile Characterization

If a stockpile was determined to be non characterized it was systematically sampled as described in the Interim Source Removal Actions: On-site Stockpiles (March 9, 2001) Work Plan. Twenty-nine stockpiles were sampled as part of this program by the following method:

- Stockpiles larger than 500 CY in size where flattened to approximately five feet in height. Each of these "flattened" stockpiles where divided into sections representing as close to 500 CY as possible and sampled. These "sections" areas were given different alphabetical designations (e.g., stockpile 510A; 510B), and were evaluated individually for disposition decisions.
- Stockpiles less than 500 CY were sampled by URS, Inc.
- Sampling was done using the following method: Five points were staked for each section. These points were staked to represent equal portions of the section. A backhoe was then used to excavate a five-foot deep hole in each of the five staked locations. The backhoe then collected a sample by scraping the entire vertical sidewall of the five-foot excavation. The sampler then collected a sample representing the entire vertical section of the sample location from the backhoe bucket. The soils obtained from the five-staked locations were composited and one sample was delivered to the laboratory for analysis.

Sampling results for these stockpiles is presented in Appendix A; laboratory analytical data validation results are presented in Appendix B.

3.4 Determination of Stockpile Disposition

There were five options available for disposition of stockpiles based upon their contaminant concentrations. They are:

- Direct Disposal Off-site: Debris that cannot be screened prior to disposal.
- Screening and off-site disposal: Soil containing arsenic and lead concentrations greater than that allowed to be placed under the golf course cap.
- Placement in Golf Course Placement Areas: Soils and debris with chemical concentrations above non-restricted cleanup levels but below the remediation levels for the golf course cap.
- General Fill: Soils and debris that have concentrations below non-restricted cleanup levels.
- Solid Waste: Brick and debris that are not hazardous waste**.**

The disposition of each stockpile was determined using the criteria presented in Table 1.

Table 1 – Stockpile Disposition Criteria

Chemical	Stockpile Disposition			
	Direct Disposal Off-Site	**Screening, then Off-Site Disposal**	**Placement in Golf Course Areas**	**General Fill**
Total DNT (mg/kg)	>3.0	N/A	<3.0	<3.0
TNT (mg/kg)	>1.75	N/A	<1.75	<1.75
Arsenic (mg/kg)	N/A	>530	>60 and <530	<60
Lead (mg/kg)	N/A	>4100	>118 and<4100	<118
TPH (mg/kg)	>250	N/A	<250	<250

N/A = Not Applicable.

4 Results

Using the criteria above, the following stockpile designations were made:

- Direct Disposal Off-Site: 14 stockpiles (approximately 6,111 CY)
- Screening, then Off-Site Disposal: 7 stockpiles (approximately 3,790 CY)
- Placement in Golf Course Areas: 139 stockpiles (approximately 46,747 CY)
- General Fill: 4 stockpiles (approximately 2,520 CY)

The designation for each individual stockpile and it's disposition is presented in Appendix C.

Appendix A

Notes:
"J" qualifier means the value is estimated; qualifier was applied during data validation.
"U" qualifier means the analyte was undetected; the value reported is the sample quantitation limit.

Appendix B

Laboratory Analytical Data Validation Results

(Prepared by URS, Inc.)

B.1 Summary

The soil sample analytical data reviewed from the Stockpile Interim Action Program are acceptable for use based on a majority of acceptable quality control data. The data meet criteria specified in the 1992 Hart Crowser Management Plan.[1] The data may be used to assess analyte concentrations with the stated qualifications.

B.2 Introduction

This section presents a quality control (QC) review of data generated from collection and analysis of soil stockpile samples from the former DuPont Works Site in Dupont, Washington, from March 19, 2001 through May 7, 2001. Samples were submitted to Sound Analytical Services, Inc. (SAS) located in Tacoma, Washington for analysis. This review includes evaluation of the following:

- Laboratory report and reporting of required analyses
- Chain of custody and holding times
- Method blanks
- Surrogate recoveries
- Matrix spike / blank spike (MS / BS)
- Laboratory duplicates
- Field duplicates
- Reporting limits

The data quality review was conducted using guidance from the following documents:

- Remedial Investigation/Feasibility Study, Former Dupont Works Site Management Plan, Hart Crowser, January 1992. (Management Plan)
- Work Plan, Interim Source Removal Actions: On-site Stockpiles, Pioneer Technologies Corporation, West Shore Corporation, NW, March 9, 2001.
- National Functional Guidelines for Inorganic Data Review, EPA, February 1994.
- National Functional Guidelines for Organic Data Review, EPA, February 1994.

Criteria used to assess the data are found in Section 5 of the Management Plan. The analytical data have been compared to criteria referenced in the Management Plan. The samples were analyzed for one or more of the following chemicals by the analytical methods shown.

- Metals (Arsenic and Lead) — EPA 6010
- Explosives (2,4-Dinitrotoluene, 2,6-Dinitrotoluene and 2,4,6-Trinitrotoluene) — EPA 8330
- Diesel range and motor oil range total petroleum hydrocarbons — NWTPH-Dx

B.3 Sample Case

The sample data groups (SDGs) identified in Table B-1 were included in this data review.

[1] Hart Crowser. January 17, 1992. Management Plan. Remedial Investigation/Feasibility Study, Former DuPont Works Site, DuPont, WA.

Table B-1 – Sample Data Groups Included in the Data Review

Sound Analytical Services Data Group Number	Date Sampled
96864	March 19, 2001
96890	March 20, 2001
96924	March 21, 2001
96959	March 22, 2001
97027	March 27, 2001

97281	April 5, 2001
97962	May 7, 2001

B.4 Laboratory Report and Reporting of Required Analyses

The laboratory reports included method blanks, surrogate recoveries, sample results, sample preparation logs, matrix spike results and matrix duplicate results. Blank spike data were reported only when matrix spike recovery data were outside of the control limits. Generally, the reports were adequate to evaluate the data quality given that blank spikes are not consistently reported. All sample analyses were reported as requested.

B.5 Chain of Custody and Holding Times

Samples were maintained under chain of custody until arrival at the laboratory. Samples were submitted to the laboratory on the day of sample collection. All sample bottles were received in good condition. The samples were digested and analyzed within the method-required holding times. Holding times were within specifications of the Management Plan.

B.6 Method and Field Blanks

Method blanks were used to determine if samples were contaminated through laboratory procedures or equipment. The laboratory method blanks were free of target analytes. The QC frequency requirement of one laboratory blank per analytical batch was met.

Field blanks (rinse blanks) were collected to assess potential cross-contamination in the field. Two rinse blanks were collected and analyzed for arsenic and lead. The field blanks were free of contamination. Data qualifiers were not assigned to associated data based on method or field blank results.

B.7 Surrogate Recoveries

Laboratory performance on individual samples was assessed by reviewing the recoveries of system monitoring compounds (surrogates).

Explosives by EPA 8330

Recoveries of the surrogate 3,4-dinitrotoluene were above the laboratory control limits of 63-119% due to sample matrix interference in seven samples in SDG 97281: (01-S648-SO- [DS-648-A-2]-C-000 (356%), 01-S648-SO- [DS-648-B-2]-C-000 (622%), 01-S648-SO- [DS-648-C-2]-C-000 (136%), 01-S648-SO- [DS-648-D-2]-C-000 (175%), 01-S648-SO- [DS-648-F-2]-C-000 (646%), 01-S648-SO- [DS-648-G-2]-C-000 (265%) and 01-S648-SO- [DS-648-H-2]-C-000 (520%)) and in seven samples in SDG 97027: (01-C648-SO- [648-DS-A]-C1-000 (287%), 01-C648-SO-[648-DS-B]-C1-000 (243%), 01-C648-SO-[648-DS-C]-C1-000 (588%), 01-C648-SO-[648-DS-D]-C1-000 (193%), 01-C648-SO-[648-DS-E]-C1-000 (129%), 01-C648-SO-[648-DS-F]-C1-000 (124%) and 01-C648-SO-[648-DS-G]-C1-000 (130%)). Sample results for 2,4,6-trinitrotoluene (2,4,6-TNT), 2,4-dinitrotoluene (2,4-DNT), and 2,6-dinitrotoluene (2,6-DNT) reported above the reporting limits for these samples have been qualified as estimated and flagged "J". Sample results reported as not detected were not qualified based on surrogate recoveries.

B.8 Matrix Spikes/Blank Spikes

Matrix spike (MS) analyses were used to assess matrix effects with respect to the analytical data. The QC frequency requirement of one MS per analytical batch or one MS per 20 samples was met. In some cases, the MS was performed on samples unrelated to this site. Samples included in SAS sample delivery groups (SDGs) 97185 and 97962 and a subset of samples included in SDGs 96890 and 96924 are associated with MS analyses performed on samples unrelated to this site. Data qualifiers were not assigned to sample data based on MS recoveries from non-project samples. Blank spike (BS) analyses were used to assess the overall performance of the analytical system when matrix spike recoveries were not acceptable.

Arsenic and Lead by EPA 6010

The MS results were compared to the method control limits of 75 to 125%. For matrix spikes performed on site samples, spike recoveries ranged from 93 to 122 percent for arsenic and 4 to 106 percent for lead. The lead recovery (4%) for the MS performed on sample 01-C625-SO- [625-A-DS]-C6-000 (SDG 96864) was outside of the control limits due to high concentrations of lead in the parent sample. Per data validation guidelines, when the concentration of the analyte in the parent sample is greater than 4X the spike level, data are not qualified based on the matrix spike recovery. Data qualifiers were not assigned to associated data based on matrix spike results.

Based on review of the sample preparation log sheets, blank spikes were prepared at the appropriate frequency although the results were reported only when MS recoveries were outside of control limits. The blank spike recoveries provided were all within the control limits of 80 to 120%. Data provided included sets of blank spike/blank spike duplicates for lead associated with samples from SDG 96864 and one set for lead associated with samples from SDG 96924 where the MS was performed on a non-project sample. Data qualifiers were not assigned to associated samples based on blank spike/blank spike duplicate results.

Explosives by EPA 8330

The recoveries of 2,4,6-TNT (72.8%) in the MS and 2,6-DNT (149%) in the MSD performed on sample 01-S648-SO- [DS-648-A-2]-C-000 (SDG 97281) were outside of the laboratory control limits of 73-108% for 2,4,6-TNT and 79-103% for 2,6-DNT. The relative percent differences (RPDs) for 2,4,6-TNT (36%) and 2,6-DNT (47%) were greater than the RPD control limits of 18% for 2,4,6-TNT and 10% for 2,6-DNT. The recoveries of 2,4,6-TNT in the MS (69.2%) and the MSD (72.3%) performed on sample 01-S648-SO-[648-DS-J]-C1-000 (SDG 97027) were outside the control limits of 73-108% for 2,4,6-TNT. Sample results for samples 01-S648-SO- [DS-648-A-2]-C-000 and 01-S648-SO- [648-DS-J]-C1-000 were previously qualified based on surrogate recovery.

Diesel Range and Motor Oil Range TPH by NWTPH-Dx

An MS/MSD was not performed on the sample submitted for diesel range and motor oil range TPH analysis. Data were assessed based on the BS/BSD results that were acceptable.

B.9 Laboratory Duplicates

Laboratory duplicate results were used to assess the precision of laboratory measurements. The laboratory duplicate results were compared to the project control limit for relative percent difference (RPD) of 35%. The QC frequency requirement of one duplicate per analytical batch or one duplicate per 20 samples was met. In some cases, the duplicate was performed on samples unrelated to this site. Samples included in SAS SDG 97185 and a subset of samples included in SDGs 96890, 96924 and 97962 are associated with duplicate analyses performed on samples unrelated to this site. Data qualifiers were not assigned to associated sample data based on duplicate results from non-project samples.

B.10 Field Duplicates

Field duplicate samples were used to assess sampling precision and representativeness. The QC frequency requirement of one field duplicate for 5 percent of the total samples collected was met for metals and explosives analyses. Eight sets of field duplicate samples (seven for metals analysis, one for explosives analysis) were collected. Table B-2 presents the RPDs of detected compounds that were calculated for the duplicate pairs. Because only one sample was analyzed for diesel-range and motor oil-range petroleum hydrocarbons, a field duplicate was not collected for this analysis.

Table B-2 – Relative Percent Differences of Detected Compounds

Sample ID	Duplicate ID	Analyte	Primary Result (mg/kg)	Duplicate Result (mg/kg)	RPD %
01-C620-SO-[620-DS-C]-C1-000	01-C620-SO-[620-DS-G]-C1-000	Arsenic	61	90	38

		2,4-DNT	0.16	0.098	48
		2,6-DNT	0.076	0.057	29

B.11 Reporting Limits

Reporting limits were reviewed to ensure that results reported meet project goals. The reporting limits are acceptable for the project needs.

Appendix C

Stockpile Designation

Table C-1 – Stockpile Disposition

Stockpile	CY	Stockpile Contents	Date Sampled	Stockpile Disposition	Rationale
Stockpiles Designated for Direct Off-Site Disposal					
503	25	Soil and Debris	Previously Characterized	Direct disposal off-site.	TPH above remediation level
504	66	Soil	Previously Characterized	Direct disposal off-site.	TPH above remediation level and from aluminum powder area
570	20	Other Debris	Previously Characterized	Direct disposal off-site.	Lead levels above remediation level
Stockpiles Disposed of Off-Site in 2001					
509/511	940	Concrete, Other Debris, Soil	Previously Characterized	Direct disposal off-site.	Contains DNT and TPH (disposed of as DNT soil)
512	2000	Concrete, Other Debris, Soil	Previously Characterized	Direct disposal off-site.	Contains DNT
609	180	Concrete, Soil	Previously Characterized	Direct disposal off-site.	TPH above remediation level
646	500	Soil	Previously Characterized	Direct disposal off-site.	Contains DNT
648A	480	Other Debris	3/27/2001	Direct disposal off-site.	Contains DNT
648B-2	250	Other Debris	4/5/2001	Direct disposal off-site.	Contains DNT
648C	480	Other Debris	3/27/2001	Direct disposal off-site.	Contains DNT
648D-2	390	Other Debris	4/5/2001	Direct disposal off-site.	Contains DNT
648F	480	Other Debris	3/27/2001	Direct disposal off-site.	Contains DNT
648H-2	250	Other Debris	4/5/2001	Direct disposal off-site.	Contains TNT
807	50	Soil	5/7/2001	Direct disposal off-site.	TPH above remediation level
Stockpiles Screened Prior to Off-Site Disposal in 2001					
607	90	Soil	Previously Characterized	Screening before off-site disposal	Arsenic and/or Lead above remediation level
629A	705	Concrete, Other Debris, Soil	3/20/2001	Screening before off-site disposal	Arsenic and/or Lead above remediation level
629B	855	Concrete, Other Debris, Soil	3/20/2001	Screening before off-site disposal	Arsenic and/or Lead above remediation level
629C	825	Concrete, Other Debris, Soil	3/20/2001	Screening before off-site disposal	Arsenic and/or Lead above remediation level
629D	825	Concrete, Other Debris, Soil	3/20/2001	Screening before off-site disposal	Arsenic and/or Lead above remediation level
629E	225	Concrete, Other Debris, Soil	3/20/2001	Screening before off-site disposal	Arsenic and/or Lead above remediation level
629F	265	Concrete, Other Debris, Soil	3/20/2001	Screening before off-site disposal	Arsenic and/or Lead above remediation level
Stockpiles Designated for Placement in Golf Course Placement Areas in 2001					
173	10	Concrete, Other Debris	Previously Characterized	PA-6	Chemical concentrations below GC PA remediation levels
177/112	175	Concrete, Other Debris	Previously Characterized	Still in Place. Will be moved to PA-6	Chemical concentrations below GC PA remediation levels
507/537/538/514/612/619	765	Concrete, Other Debris	Previously Characterized	Still in Place. Will be moved to PA-1	Chemical concentrations below GC PA remediation levels
510A	210	Concrete, Other Debris	3/19/2001	PA-1	Chemical concentrations below GC PA remediation levels
510B	210	Soil	3/19/2001	PA-1	Chemical concentrations below GC PA remediation levels

Chapter 1 – Introduction

1.1 2001 Interim Corrective Actions

This report describes the interim corrective actions (ICAs) that were undertaken during 2001 at the former DuPont Works Site (Site) within the Parcel One Consent Decree Boundary. The Site is located in the City of Dupont, Pierce County, Washington (see Figure 1-1). The ICAs involved excavation of contaminated soil, verification sampling of excavated areas, and stockpiling of contaminated soil for on-Site placement or off-Site disposal. ICAs were conducted as allowed under the July 1991 Consent Decree signed by the Weyerhaeuser Company (Weyerhaeuser), E.I. duPont de Nemours and Company (DuPont), and the Washington State Department of Ecology (Ecology). ICAs included soil excavation and sampling in the following areas (see Figure 1-2):

- Building Foundations (Foundations).
- The Narrow Gauge Railroad (NGRR) outside the Golf Course land use footprint.
- Hot spots:
    - Arsenic and Lead Areas (Sequalitchew Creek NGRR, Area 38, and an area within the "Areas for Additional Sampling Site-Wide Grid" (Row 71, Column 85 of [R71C85])).
    - 2,4-Dinitrotoluene (2,4-DNT), 2,6-dinitrotoluene (2,6-DNT), and 2,4,6-trinitrotoluene (TNT) Areas (Areas 10 and 18).
- Topsoil Laydown Areas.

All work was performed under the direction of the Project's Management Team (MT). West Shore Corporation, NW (WSNW) oversaw the program on a day-to-day basis. URS, Inc. (URS) performed the verification sampling and Sound Analytical Services served as the project laboratory. PIONEER Technologies Corporation (PIONEER) managed the analytical data. ESM Consulting Engineers, LLC (ESM) surveyed the excavation boundaries and sample locations. Active Construction (ACTIVE) was the remediation contractor. The program was initiated in the first quarter of 2001 and was completed in September 2001.

1.2 Background

Historical soil sampling at the Site identified concentrations of lead, arsenic, DNT, and TNT above Site-specific remediation levels. Remediation levels are Site-specific cleanup standards for humans that were developed using exposure assumptions and other media-specific factors that reflect future planned land uses for the Site. These areas are described below:

- Elevated lead concentrations were found in soil adjacent to building foundations. The source of this lead was lead sheeting that had been used to line the buildings, and lead-based paint chips remaining after building demolition.
- Elevated arsenic concentrations were found associated with the NGRR, where an arsenic-containing herbicide had been used for weed control for fire protection.
- 2,4-DNT, 2,6-DNT, and TNT, explosives that were manufactured on-Site, were found in elevated concentrations in a former industrial manufacturing area (Area 10), and in a historical "hot spot" area (Area 18).

- Hot spot areas of arsenic and/or lead contamination were found in soil along the Sequalitchew Creek NGRR, and in one location in the "Areas for Additional Sampling Site-Wide Grid".

The planned land uses within the Parcel 1 Consent Decree Boundary include open space, commercial, industrial, historical, and a golf course. In preparation for these future land uses, areas with elevated concentrations of constituents of concern were identified for soil removal and either on-Site placement or off-Site disposal. Table 1-1 presents the ICA soil placement criteria.

During the ICA programs, soil in the selected areas with elevated arsenic, lead, 2,4-DNT, 2,6-DNT, and/or TNT levels were excavated until concentrations were reached that could: either be left in place (met Site-specific remediation levels), moved to placement areas, processed at the soil screening plant, or stockpiled for off-Site disposal. In addition to the foundation, narrow gauge railroad, and other miscellaneous hot spot areas, soil was excavated in areas where clean topsoil is being stored for future use during development of the cap/containment areas`.

1.3 Objectives

The objectives of the ICAs were to:

- Excavate the top 2 feet of soil around selected foundations outside of the proposed golf course land use footprint.

- Excavate the top 1.5 feet of soil along the total length of NGRR outside the proposed golf course land use footprint.

- Excavate the top 1.5 feet of soil in remaining hot spot areas that may require on-Site screening and/or off-Site disposal.

- Excavate soil to provide clean areas for clean topsoil storage that will be used for the future cap/containment areas.

The Foundation, NGRR, Hot Spots, and Soil Laydown ICAs are discussed in detail below.

Chapter 2 – Interim Corrective Actions

ICAs were conducted as allowed under the July 1991 Consent Decree signed by Weyerhaeuser, Dupont and the Washington State Department of Ecology. The processes and results of each interim corrective action are discussed below separately by area.

2.1 Site Preparation Activities

In preparation for the ICAs the following Site preparation activities took place:

- A work plan was prepared and submitted to the Department of Ecology (Dec. 6, 2000).
- Permission was obtained from Ecology to proceed with the work.
- The areas to be excavated were located by ESM and the excavation boundaries were surveyed.
- Vegetation was removed within 50 feet of the foundations, within 25 feet of either side the NGRR centerline, and any additional areas needed to safely complete the work.
- With the exception of work done along the NGRR within Sequalitchew Creek Canyon, Site preparation did not include any removal of track or ties. This work had been completed in the past.

2.2 Foundation Excavations

Soil was excavated around the foundations of buildings that were known to have been explosive storage locations or were painted with lead-based paint. The locations of these excavations are shown in Figure 2-1. The excavation procedure and verification sampling procedure and results are described below.

2.2.1 Excavation Procedure

ACTIVE excavated the top 2 feet of soil within 25 feet of each foundation. The excavated soil was hauled by truck to the nearest placement area and placed. Site characterization sampling had shown that soil concentrations in the areas surrounding foundations were acceptable for placement in placement areas. After verification samples were taken, it was necessary to perform an additional one-foot excavation around some of the building foundations to achieve the Site-specific remediation level of 60 mg/kg for arsenic and the 118 mg/kg screening concentration for lead. Areas where additional excavation was necessary are shown in Figure 2-1. The soil removed during additional round(s) of excavation was deposited in the nearest placement areas.

2.2.2 Verification Sampling

Following excavation, verification soil sampling was conducted. Verification samples were collected on the excavation floor and on each side of the foundation (See Figure 2-2). To ensure that adequate characterization had been done, each of the samples consisted of a composite of 5 different locations. Further details of the sampling design are described in the Interim Source Removal Action Work Plan (PIONEER and West Shore, 2000). Verification sampling results are shown in Appendix A, Table A-1. The data validation report describing sample quality control procedures is presented in Appendix B.

2.2.3 Verification Sampling Results

A total of 267 locations were sampled around building foundations. Of these locations, 3 required two additional rounds of excavation and sampling, and 8 required three additional rounds of excavation and sampling. The arsenic Site-specific remediation level of 60 mg/kg was met at all locations (the highest result was 60 mg/kg), however there were 7 locations where the lead screening level of 118 mg/kg was

not met. Lead concentrations in these locations ranged from 120 mg/kg up to 520 mg/kg. Remediation of these areas will be addressed in the Feasibility Study Report, which is currently being prepared.

2.3 Narrow Gauge Railroad Tracks

The sections of NGRR included in this program were located outside the future golf course land use footprint, and south of Sequalitchew Creek. Some areas of the NGRR along the main paved road were not excavated due to the presence of merchantable timber. Timber harvesting is planned to allow access to all potentially contaminated soil. Harvesting requires a Forest Practices Act Permit, and will be conducted at a later time. The locations of the NGRR excavations are shown in Figure 2-3. The excavation and verification sampling procedures and results are described below.

2.3.1 Excavation Procedure

ACTIVE excavated the top 1.5 feet of soil within 25 feet from the centerline of the NGRR. Both sides of the rail bed were excavated first, followed by the rail bed itself. The excavated soil was hauled by truck to the nearest placement area and placed. Site characterization sampling had shown that soil concentrations in the NGRR track areas were acceptable for placement.

2.3.2 Verification Sampling

Following excavation, verification soil sampling was conducted. One five-point composite verification sample was collected from the excavation floor every 50 feet along the NGRR (see Figure 2-4). This resulted in 50 x 50 foot boxes with one five-point composite verification sample from each box. Each sample was composited from soil taken in the middle of the track and soil taken on both sides of the track, no more than 10 feet from the track centerline. Where verification samples exceeded the Site-specific remediation level of 60 mg/kg for arsenic and/or the 118 mg/kg lead screening level, the 50 x 50 foot box was excavated an additional vertical foot. Areas where additional excavation was necessary are shown in Figure 2-3. The soil removed during additional round(s) of excavation was also hauled to the nearest placement area and placed. Further details of the sampling design are shown in the Interim Source Removal Action Work Plan (PIONEER and West Shore 2000). Verification sampling results are shown in Appendix A, Table A-2. The data validation report describing sample quality control procedures is presented in Appendix B.

2.3.3 Verification Sampling Results

A total of 392 locations were sampled along the former NGRR. Of these locations, 21 required one additional round of excavation and sampling and 2 required two additional rounds of excavation and sampling to meet the concentration criteria for remaining on-Site. One sample with an arsenic concentration of 89 mg/kg exceeded the Site-specific remediation level of 60 mg/kg. The highest remaining lead concentration was 110 mg/kg.

2.4 Hot Spot Areas: Arsenic and Lead

During this ICA, three areas with elevated arsenic and/or lead levels were excavated. These were, the NGRR locations along the Sequalitchew Creek, Area 38, and one location (row 71, column 85 or R71C85) located on the “Areas for Additional Sampling Site-Wide Grid”. These areas were excavated in order to include them in the 2001 Soil Screening Program. The location of these excavations is shown in Figure 2-5. The excavation procedure, verification sampling procedure, and results are described below.

2.4.1 Excavation Procedure

Sequalitchew Creek NGRR

ACTIVE excavated all soil along the NGRR track bed, out to a distance of 25 feet of the NGRR centerline but not over the bank, to an initial depth of 2 feet below ground surface (BGS). The sides of the rail bed were excavated first, followed by the rail bed itself. The excavated soil was hauled by truck to the screening plant stockpile. After excavation, the centerlines of the NGRR were re-staked to aid in

verification sampling. Verification samples were collected from five areas of the NGRR along Sequalitchew Creek.

Areas for Additional Sampling Site-Wide Grid Area R71C85 and Area 38

In preparation for excavation, ESM located and flagged the locations to be excavated and outlined the initial excavation limit. This was set at 25 feet in the north, south, east and west directions from the original sample location. This resulted in a 50-by-50 foot initial excavation. After preparation work, ACTIVE excavated all soils within the staked area to an initial depth of 1.5 feet BGS for R71C85 and 2 feet BGS for Area 38. The excavated soil was hauled by truck to the screening plant soil stockpile.

2.4.2 Verification Sampling

Following excavation, verification soil sampling was conducted as described below for each area.

Sequalitchew Creek NGRR

Following excavation, one five-point composite verification sample was collected from the excavation floor every 75 feet along the NGRR. This resulted in seven 75 x 25 foot boxes, with one five-point verification sample obtained from each box. Each sample was composited from soil taken in the middle of the track and soil taken on both sides of the track, no more than 10 feet from the track centerline. The sampling design is the same as those shown for the NGRR in the Interim Source Removal Action Work Plan and is presented in Figure 2-6 (PIONEER and West Shore, 2000). Verification sampling results are shown in Appendix A, Table A-3. The data validation report describing sample quality control procedures is presented in Appendix B.

Ecology requested that characterization samples be collected along transects perpendicular to Sequalitchew Creek to confirm that arsenic concentrations were not elevated from the edge of the NGRR track bed down to the creek bed. Three composite samples were collected in areas selected by Ecology. The first 0 to 6 inch sub-sample of the composite was collected 2 feet down the slope from the NGRR track bed. Additional sub-samples were collected every 20 feet down the bank until the creek was reached. No sub-samples were collected in Sequalitchew Creek. In addition, 5 discrete samples were collected at one of the locations in order to determine if there was a potential concentration gradient. The first sample was collected 2 feet down the slope from the NGRR track bed and then additional discrete samples were collected every 5 feet until the Sequalitchew Creek bed was reached. Characterization sampling results are shown in Appendix A, Table A-4. The data validation report describing sample quality control procedures is presented in Appendix B.

Areas for Additional Sampling Site-Wide Grid Area R71C85 and Area 38

Following excavation, verification soil sampling was conducted. Verification samples were collected from the excavation bottom as well as adjacent to the excavation on each side, for a total of 5 samples for R71C85. For the Area 38 excavation, there were only 3 sides to the excavation due to an adjacent excavation. In this case a total of 4 samples were taken, one adjacent to each of the three walls and one on the bottom of the excavation. To ensure adequate characterization, the sample collected on the floor of the excavation consisted of a composite of 5 different locations. Adjacent to each sidewall, one discrete sample was taken. Verification sampling results are shown in Appendix A, Table A-5. The data validation report prepared describing sample quality control proceedures was prepared by URS, and is presented in Appendix B.

2.4.3 Verification Sampling Results

Sequalitchew Creek NGRR

Verification samples were collected from 7 locations along the Sequalitchew NGRR. There were 5 locations where the arsenic Site-specific remediation level of 60 mg/kg was not met. At these locations, the arsenic levels ranged from 67 mg/kg to 130 mg/kg. In addition, there were 7 locations where the lead screening level of 118 mg/kg was not met. In these locations, the lead levels ranged from 190 mg/kg to

2,900 mg/kg. Remediation of these areas will be addressed in the Feasibility Study Report, which is currently being prepared.

All of the transect sample arsenic soil concentrations were below background concentrations and Site-specific remediation levels. The only location where the lead concentration was elevated was at 600E, which was the location of a lead hot spot. Additional discrete samples were collected and demonstrated that the elevated lead concentration was only present 2 feet down the slope from where the NGRR track bed had sluffed off (see Figure 2-6).

Areas for Additional Sampling Site-Wide Grid Area (Row 71, Column 85) and Area 38

A total of 9 locations were sampled in these two areas (5 in Row 71, Column 85 area; 4 in Area 38). In the Row 71, Column 85 location, the highest remaining arsenic concentration was 55 mg/kg. The highest remaining lead concentration was 99 mg/kg. In Area 38, there was 1 location where the arsenic Site-specific remediation level of 60 mg/kg was not met. At this location, the arsenic level was 330 mg/kg. The lead screening level of 118 mg/kg was met at all locations sampled. The highest remaining lead concentration was 44 mg/kg. Remediation of the area with the elevated arsenic concentration will be addressed in the Feasibility Study Report, which is currently being prepared.

2.5 Hotspot Areas: 2,4-DNT, 2,6-DNT, and TNT

During this ICA, two areas with elevated 2,4-DNT, 2,6-DNT, and/or TNT were excavated. These are Area 10 and Area 18. The locations of these excavations are shown in Figure 2-7. The excavation and verification sampling procedures and results are described below.

2.5.1 Excavation Procedure

Prior to excavation ESM located and flagged each location to be excavated. Next, they staked the initial excavation limit set at 25 feet in the north, south, east and west directions from the original sample location for the Area 18 sample. This resulted in a 50-by-50 foot initial excavation. The initial excavation limit in Area 10 was set at 15 feet in the north, south, east, and west directions from the original sample because the area had been excavated previously. ACTIVE excavated the top 3 feet of soil within the Area 18 staked area and the top 3 feet of soil within the Area 10 staked area. The excavated soil was hauled by truck to the appropriate DNT or TNT stockpile for off-Site disposal.

2.5.2 Verification Sampling

Following excavation, verification soil sampling was conducted. In Area 18, one verification sample was collected on the excavation floor. In Area 10, because of the depth of the excavation, verification samples were collected on the excavation floor as well as on each sidewall of the excavation, for a total of 5 samples in Area 10. To ensure adequate characterization, the sample collected on the floor of the excavation consisted of a composite of 5 different locations. On each wall of the excavation, one discrete sample was taken. Verification sampling results are shown in Appendix A, Table A-6. The data validation report describing sample quality control procedures is presented in Appendix B.

2.5.3 Verification Sampling Results

Area 10

A total of 5 locations were sampled in this area. Sample results from the second round of excavation all met the arsenic and lead criteria for remaining on-Site. The only analyte detected in samples was TNT, and the highest detected concentration was 0.2 mg/kg. This is below the Site-specific cleanup level of 1.75 mg/kg (Ecology, 2001).

Area 18

One sample was collected in this area. Sample results from this first round of excavation met the criteria for remaining on-Site. The analytes detected were 2,4-Dinitrotoluene and Total DNT. The highest

detected concentrations were 0.023 mg/kg and 0.046 mg/kg, respectively. These concentrations are below the Site-specific cleanup level of 3.0 mg/kg for total DNT (Ecology, 1996).

2.6 Topsoil Laydown Areas

Two areas designated for storage of clean topsoil were excavated during this ICA. The locations of these areas are shown in Figure 2-8. The objective of the topsoil laydown ICA was to remove potentially contaminated surface soil from these areas so that they could be used for stockpiling of clean topsoil. This topsoil will be used in the development of the future cap/containment areas. The excavation and verification sampling procedures and results are described below.

2.6.1 Excavation Procedure

ACTIVE excavated soil within the staked area to an initial depth of 1.5 feet BGS. The excavated soil was hauled by truck to the nearest placement area and placed. Site characterization sampling had shown that soil concentrations in these areas were acceptable for placement areas.

Areas where verification samples exceeded the Site-specific remediation level of 60 mg/kg for arsenic and/or the 118 mg/kg lead screening level were excavated an additional foot. Areas where additional excavation was necessary are shown in Figure 2-8. The soil removed during the additional rounds of excavation was also hauled to placement areas and placed.

2.6.2 Verification Sampling

Following excavation, verification soil sampling was conducted. Verification samples were collected using a 150-foot grid, and one discrete sample was collected per grid node. The starting point for the excavation grid was related to the Site-wide 150-foot sample grid. Verification sampling results are shown in Appendix A, Table A-5. The data validation report describing sample quality control procedures is presented in Appendix B.

2.6.3 Verification Sampling Results

A total of 13 locations were sampled in the topsoil laydown areas. Of these samples, 1 (R34C15) exceeded the criteria, requiring a second round of excavation and sampling at that location. The highest remaining arsenic concentration was 33 mg/kg and the highest remaining lead concentration was 96 mg/kg.

2.7 Archeological Monitoring

All activities that disturbed in place soil greater than eight inches in depth and less than three feet in depth were monitored by either Gary Wesson and Associates, Inc. (WESSON) or Historical Research Associates (HRA); both qualified archeological consulting firms. Five occurrences of potential historical or cultural artifacts were discovered during ICA field work. They are:

- Historic Scatter near the 1833 Fort Nisqually: Content included china fragments, a clear bottle base, a china cup fragment, and a fragment of a large metal pipe.

- Potential Small Midden near the 1833 Fort Nisqually: 13 meter long potential deposit containing sparse *in situ* shell and animal bone thought to be associated with the 1833 Fort Site.

- Historic Scatter near the Site Fence Line: Content included Hudson Bay era colored glass, plate fragments, a small teacup base and assorted metal fragments.

- Two Potential Small Middens located in the Southwest Corner of the Site: Two very small, both less than 2 square meters in size, shallow accumulations of shell. It is believed that neither location is *in situ*.

- Faunal Remains in the Southern Portion of the Site: Small occurrence of elk teeth, broken mammal bones and three small mussel fragments. Occurrence is not *in situ* and lacks integrity.

Each of these areas was protected against further disturbance and will be further evaluated during 2002 to determine if they are sites of Historic significance. WESSON/HRA's monitoring report, entitled *Interim Archaeological Monitoring Report for the Former DuPont Works Site, Parcel 1*, is available at the Office of Archaeology and Historic Preservation in Olympia, Washington or upon request.

Chapter 3 – Conclusions

A total of 731 samples were collected and analyzed for the 133 ICA excavation locations on the Site. Based on the evaluation of sample data, all of the locations sampled during this ICA met the Site-specific remediation level for arsenic of 60 mg/kg, the lead screening level of 118 mg/kg, and 2,4-DNT, 2,6-DNT, and TNT Site-specific remediation levels except:

- There were 7 locations where the Site-specific remediation levels for arsenic of 60 mg/kg were not met.

- There were 13 locations where the lead screening level of 118 mg/kg was not met.

However, all of the arsenic and lead sample results were below the placement area remediation levels. Potential remediation of these locations will be addressed in the Feasibility Study Report, which is currently being prepared.

In all sampled locations, levels of 2,4-DNT, 2,6-DNT, and TNT were below Site-specific remediation levels of 3.0 mg/kg for total DNT and 1.75 mg/kg for TNT (Ecology 1996; 2001).

Tables and Figures

Table 1-1 – Interim Corrective Action Soil Placement Criteria

Constituent	Concentration in Soil Left In Place (mg/kg)	Concentration in Soil moved to Placement Areas (mg/kg)	Concentration in Soil Stockpiled for On-Site Screening and/or Off-Site Disposal (mg/kg)
Arsenic	≤60	>60 and ≤530	>530
Lead	≤118	> 118 and ≤4100	>4100
2,4-Dinitrotoluene	≤1.5[(a)]	NA	≥1.5
2,6-Dinitrotoluene	≤1.5[(a)]	NA	≥1.5
2,4,6-Trinitrotoluene	≤1.75	NA	>1.75

Notes:
NA: Soil with 2,4-Dinitrotoluene, 2,6-Dinitrotoluene, or 2,4,6-Trinitrotoluene concentrations greater than those that could be left in place were stockpiled for off-Site disposal.
[(a)] Ecology approved a Site-specific number of 3.0 mg/kg for total DNT.

Appendix A – Analytical Data

Verification sampling data from the interim corrective actions is presented in this Appendix. Where multiple excavations were necessary, only the last round of sampling data is presented. Therefore, the concentrations that appear in these tables are the concentrations that are currently in place. Sample numbers that have a "-" extension (e.g., F-08-2), the number following the dash indicates the number of samples (and hence the number of excavations) that occurred at that location. Shaded values indicate concentrations that exceeded the Site-specific remediation level of 60 mg/kg for arsenic or the lead screening level of 118 mg/kg.

Table A-1 – Soil Verification Sample Results for Foundation Areas

Sample ID	Short ID	Arsenic (mg/kg)	Qualifier	Lead (mg/kg)	Qualifier

Appendix B – Laboratory Analytical Data Validation Results

(Prepared by URS, Inc.)

Summary
The soil sample analytical data reviewed for the 2001 Interim Corrective Actions at the Former DuPont Works Site in DuPont, Washington are acceptable for use based on a majority of acceptable quality control data. The data meet criteria specified in the 1992 Hart Crowser Management Plan.[1] The data may be used to assess analyte concentrations with the stated qualifications.

Introduction
This section presents a quality control (QC) review of data generated from collection and analysis of samples for the 2001 Interim Corrective Actions at the former DuPont Works Site in Dupont, Washington, from May 7, 2001 through September 19, 2001. Samples were submitted to Sound Analytical Services, Inc. (SAS) located in Tacoma, Washington for analysis. This review includes evaluation of the following:

- Laboratory report and reporting of required analyses
- Chain of custody and holding times
- Method blanks
- Surrogate recoveries
- Matrix spike / blank spike (MS / BS) recoveries
- Laboratory duplicates
- Field duplicates
- Reporting limits

The data quality review was conducted using guidance from the following documents:

- Remedial Investigation/Feasibility Study, Former Dupont Works Site Management Plan, Hart Crowser, January 1992. (Management Plan)
- Work Plan, Interim Source Removal Actions: Impacted Foundations and Narrow Gauge Railroad Beds at the Former DuPont Works Site, Dupont, Washington, Pioneer Technologies Corporation, West Shore Corporation, NW, December 6, 2000.
- National Functional Guidelines for Inorganic Data Review, EPA, February 1994.
- National Functional Guidelines for Organic Data Review, EPA, February 1994.

Criteria used to assess the data are found in Section 5 of the Management Plan. The analytical data were compared to criteria referenced in the Management Plan. The samples were analyzed for one or more of the following chemicals by the analytical methods shown:

- Metals (Arsenic, Lead and/or 23 metal target analyte list) EPA 6000/7000 series
- Explosives (2,4-Dinitrotoluene, 2,6-Dinitrotoluene and 2,4,6-Trinitrotoluene) EPA 8330
- Diesel-range and motor oil-range total petroleum hydrocarbons (TPH) NWTPH-Dx

Sample Case
The sample data groups (SDGs) presented in Table B-1 were included in this data review.

Laboratory Report and Reporting of Required Analyses
The laboratory reports included method blanks, surrogate recoveries (if appropriate), sample results, sample preparation logs, matrix spike results and matrix duplicate results. Blank spike data were reported for all organic analyses and were reported for metals only when matrix spike recovery data were outside of the control limits. Generally, the reports were adequate to evaluate the data quality given that blank spikes are not consistently reported. All sample analyses were reported as requested.

Chain of Custody and Holding Times

[1] Hart Crowser. January 17, 1992. Management Plan. Remedial Investigation/Feasibility Study, Former DuPont Works Site, DuPont, WA.

Samples were maintained under chain of custody until arrival at the laboratory. With the exception of the samples collected on September 10, 2001 (SAS # 100780), samples were submitted to the laboratory on the day of sample collection. All sample bottles were received in good condition. All samples were digested or extracted and analyzed within the method-required holding times.

Method and Field Blanks

Method blanks were used to determine if samples were contaminated through laboratory procedures or equipment. The laboratory method blanks were free of target analytes. The QC frequency requirement of one laboratory blank per analytical batch was met.

Field blanks (rinse blanks) were collected to assess potential cross-contamination in the field. Forty-five (45) field blanks were collected and analyzed for arsenic and lead. Arsenic was detected in 2 of the field blanks at concentrations of 0.02 mg/L and 0.01 mg/L. These field blanks are associated with the analytical groups 98830 and 100052, respectively. Lead was detected in 15 field blanks at concentrations ranging from 0.01 mg/L to 0.11 mg/L. These field blanks are associated with the analytical groups 98976, 99001, 99474, 99620, 99660, 99700, 99729, 99996, 100020, 100052, 100171, 100198, 100330, 100606 and 100645. Concentrations of arsenic and lead detected in the soil samples associated with these field blanks typically were reported with significantly higher concentrations of the metals (i.e. greater than 10X the concentration in the field blank). Data qualifiers were not assigned to associated soil analytical data based on method or field blank results.

Surrogate Recoveries

Laboratory performance on individual samples analyzed for explosives and TPH was assessed by reviewing the recoveries of system monitoring compounds (surrogates). Surrogate recoveries for samples analyzed for explosives and TPH were acceptable and data qualifiers were not assigned.

Matrix Spikes/Blank Spikes

Matrix spike (MS) analyses were used to assess matrix effects with respect to the analytical data. The QC frequency requirement of one MS per analytical batch or one MS per 20 samples was met. In some cases, the MS was performed on samples unrelated to this Site. Thirty (30) SDGs contained MS analyses on samples unrelated to this Site. These SDGs are listed in the Laboratory Duplicates section of this report. Data qualifiers were not assigned based on results from MS analyses performed on samples unrelated to this Site. Blank spike (BS) analyses were used to assess the overall performance of the analytical system when matrix spike recoveries were not acceptable.

Arsenic and Lead by EPA 6010

The MS results were compared to the method control limits of 75 to 125%. The lead recovery (376%) and the arsenic recovery (51%) for the MS performed on sample 01-OS02-SS[LR-68-600E-TRANSECT]-C1-000 (SDG 100529) were outside of the control limits. Per data validation guidelines, when the concentration of the analyte in the parent sample is greater than 4X the spike level, data are not qualified based on the MS recovery. Lead results were not qualified due to the MS recovery in sample 01-OS02-SS[LR-68-600E-TRANSECT]-C1-000 based on the 4X rule. Results for arsenic in the samples in the same analytical batch as 01-OS02-SS[LR-68-600E-TRANSECT]-C1-000 (SDG 100529) were qualified as estimated and flagged “J” or “UJ” based on MS results.

The recovery of lead (44%) in the MS performed on sample 02-N01-SS[NGRR-145-2]C2-025 (SDG 100558) was below the control limits due to sample matrix interference. Results for lead for samples in the same analytical batch as sample 02-N01-SS[NGRR-145-2]C2-025 (SDG100558) were qualified as estimated and flagged “J” based on the MS results. The results for arsenic in SDG 100558 were not qualified.

Based on review of the sample preparation log sheets, blank spikes were prepared at the appropriate frequency. The results were reported only when MS recoveries were outside of control limits. The blank spike recoveries provided were all within the control limits of 80% to 120%. Data provided included sets of blank spike/blank spike duplicates for lead associated with samples from SDGs 100529 and 100558 and arsenic associated with samples from SDG 100529. Blank spike/blank spike duplicate data were also provided for chromium and nickel associated with samples from SDG 99002 and lead associated

with samples from SDG 100375, where the MS was performed on a non-project sample. Data qualifiers were not assigned to associated samples based on blank spike/blank spike duplicate results.

Explosives by EPA 8330

The recovery of 2,4,6-trinitrotoluene (2,4,6-TNT) in the MS (1,900 %) and the recoveries of 2,4-dinitrotoluene (2,4-DNT, 465%), 2,6-dinitrotoluene (2,6-DNT, 132%) and 2,4,6-TNT (200,000%) in the MSD performed on sample 03-IN01-SS[10-VS-5]D2-7.0 (SDG 99905) were outside of the laboratory control limits of 69–110% for 2,4,6-TNT, 78-105% for 2,4-DNT, and 68-108% for 2,6-DNT. The relative percent differences (RPDs) for 2,4,6-TNT (200%), 2,4-DNT (130%) and 2,6-DNT (21%) were greater than the RPD control limits of 9%, 13%, and 10% for 2,4,6-TNT, 2,4-DNT and 2,6-DNT, respectively. Recoveries of explosives in the blank spike/blank spike duplicate were acceptable. Results for 2,4,6-TNT, 2,4-DNT and 2,6-TNT for sample 03-IN01-SS[10-VS-5]D2-7.0 were qualified as estimated and assigned "J" or "UJ" flags based on MS/MSD results.

Laboratory Duplicates

Laboratory duplicate results were used to assess the precision of laboratory measurements. The laboratory duplicate results were compared to the project control limit for relative percent difference (RPD) of 35% when sample results were greater than or equal to five times the reporting limit. A control limit of plus or minus the reporting limit was used for evaluation of duplicate samples where one or both of the results are less than five times the reporting limit. The QC frequency requirement of one duplicate per analytical batch, or one duplicate per 20 samples was met. In some cases, the duplicate was performed on samples unrelated to this Site. Thirty (30) SDGs include samples or subsets of samples that are associated with duplicate analyses performed on samples unrelated to this Site (See Table B-2). Data qualifiers were not assigned to sample data based on duplicate analyses of non-project samples.

Arsenic and Lead by EPA 6010

A total of sixty-two samples were qualified as estimated based on the results of laboratory duplicate analyses. All qualified results for metals analysis are summarized in Table B-2. Of the samples qualified based on laboratory duplicates, 20 samples were qualified due to an RPD that is greater than 35% and 42 sample results were qualified due to a difference of greater than the reporting limit between a sample and its duplicate. Qualified data were assigned "J" flags if the sample result was reported as detected and "UJ" flags if reported as not detected.

Explosives by EPA 8330

Second column confirmation for detected compounds was performed on samples analyzed for explosives by EPA Method 8330. The RPDs of the results were evaluated by the laboratory and found to be greater than 40% for 2,4,6-TNT in samples 03-IN01-SS[10-VS-8]D2-5.0, 03-IN01-SS[10-VS-9]D2-5.0 and 03-IN01-SS[10-VS-10]D3-5.0, and for 2,4-DNT in sample 03-IN01-SS[10-VS-5]D2-7.0 (SDG 99905). Sample results were qualified as estimated and flagged with a "J" for 2,4,6-TNT in samples 03-IN01-SS[10-VS-8]D2-5.0, 03-IN01-SS[10-VS-9]D2-5.0 and 03-IN01-SS[10-VS-10]D3-5.0 and for 2,4-DNT in sample 03-IN01-SS[10-VS-5]D2-7.0.

Field Duplicates

Field duplicate samples were used to assess sampling precision and representativeness. The QC frequency requirement of one field duplicate for 5 percent of the total samples collected was met for metals and explosives analyses. Forty-nine (49) sets of field duplicate samples for metals analysis were collected, and one set of duplicate samples were collected for explosives. A field duplicate was not collected for diesel-range and motor oil-range TPH analysis. Tables B-3 and B-4 present the RPDs of detected compounds that were calculated for the duplicate pairs of soil samples analyzed for metals and explosives.

Reporting Limits

Reporting limits were reviewed to ensure that results reported meet project goals. The reporting limits are acceptable for the project needs. The data are summarized in Appendix A.

Arsenic and Lead by EPA 6010

The samples analyzed on August 23, 2001 were reported with elevated PQLs. This affects the samples collected on August 20, 2001 (SDG 100280) and a subset of samples collected August 21, 2001 (SDG 100308). The typical PQLs for lead and arsenic analyses performed on soil samples for this project were approximately 2 mg/kg for both metals. Samples analyzed on August 23, 2001 were reported with PQLs of approximately 20 mg/kg for lead and 40 mg/kg for arsenic. The soil screening level for lead and the Site-specific remediation level for arsenic (118 mg/kg and 60 mg/kg, respectively) are greater than the elevated PQLs reported for the August 23 analyses, therefore the elevated PQLs do not affect the use of these data for project objectives.

Explosives by EPA 8330

The result for 2,4-DNT reported by the laboratory for sample 18-TR-18N,S-1 (0.023 mg/kg) was below the reported PQL for 2,4-DNT (0.045 mg/kg). The laboratory assigned a "J" flag to the sample result, as they typically do when reporting below the PQL. The Corps of Engineers requires SAS to report all confirmed detections of explosives even if compounds are detected below the PQL.

1 Introduction

This Report presents the analytical results from post-excavation verification soil samples collected between June 24 and July 24, 2002 as part of an interim corrective action (ICA) conducted at the former DuPont Works Site (Site) within the Parcel One Consent Decree Boundary. The Site is located in the City of Dupont, Pierce County, Washington (see Figure 1-1). The ICA involved excavation of soil and verification sampling of the excavated areas. This ICA was conducted as allowed under the July 1991 Consent Decree signed by the Weyerhaeuser Company (Weyerhaeuser), E.I. duPont de Nemours and Company (DuPont), and the Washington State Department of Ecology (Ecology). The ICA included soil excavation and sampling in the following areas:

- 250 Foot Perimeter Soil Area (see Figures 3-1 through 3-5)
- Future Storm Water Runoff Overflow Pipeline (see Figures 3-6 and 3-7)

All work was performed under the direction of the Project's Management Team (MT). West Shore Corporation, NW (WSNW) oversaw the program on a day-to-day basis. PIONEER Technologies Corporation (PIONEER) performed the verification sampling, and managed the analytical data. Severn Trent Laboratories, Inc. (STL) served as the project laboratory. Ethix performed the data quality control review. Active Construction (ACTIVE) surveyed the excavation boundaries and sample locations and served as the remediation contractor. The program was initiated in June 2002 and was completed in July 2002.

2 Objectives

The objectives of this ICA was to:

1. Minimize any potential impacts of wind blown dust generated during the removal of Site soil to future residences that will be constructed in the near future, south of the Site (i.e., outside the consent decree boundary).

2. Ensure that the constituent concentrations in soil are in compliance with the Washington State Model Toxics Control Act (MTCA). The constituent concentrations in soil cannot exceed 60 mg/kg for arsenic and 118 mg/kg for lead, which are site-specific levels established by Ecology that are protective of human health and the environment.

3 Summary of Activities

The goal of this program was to remove 1 foot of soil and confirm that the resulting soil concentrations are below the Site-specific cleanup goals. Excavation activities were undertaken to remove 1 foot of soil at the following two locations:

3.1 250 Foot Perimeter Soil Area

Approximately 1 foot of soil was excavated within 250 feet of the southern Site consent decree boundary (see Figures 3-1 through 3-4). A discrete sample was then collected from each node on the 75-foot sampling grid from a depth of 0 to 6 inches. The verification samples were delivered, under chain of custody, to STL for analysis. On July 9, 2002 an additional foot of soil was removed at the sampling grid location R81C41 because the initial verification sample result (144 mg/kg) exceeded the cleanup goal for lead. The limit of the additional excavation was determined by going half way to the surrounding grid points. In other words, soil was excavated 37.5 feet in every direction from the sampling grid point which resulted in a 75-foot by 75-foot excavation. Figure 3-5 identifies where this additional excavation was undertaken and the associated post-excavation verification sample location.

3.2 Future Storm Water Runoff Overflow Pipeline

Approximately 1 foot of soil was excavated within an approximate 50-foot by 25-foot box surrounding each of the pipeline sample locations (see Figure 3-6). A 5-point composite verification sample was collected from the bottom of each excavation at a depth of 0 to 6 inches. On July 24, 2002 an additional foot of soil was removed from two sample locations (PL-8 [arsenic = 109 mg/kg] and PL-12 [arsenic = 80 mg/kg]) where the results of the first round of verification samples exceeded the cleanup goal for arsenic. The limit of the additional excavation was determined by excavating half way to the next sampling point. This resulted in excavations that were approximately 25 by 50 feet. Figure 3-7 identifies these locations. The verification samples were delivered, under chain of custody, to STL for analysis.

3.3 Results

The analytical results are presented in Table 3-1. These data were assessed for accuracy and precision, and no data were qualified indicating the absence of matrix interferences (see Attachment A).

4 Conclusions

A total of 184 samples were collected at the base of each excavation and the soils were analyzed using EPA Methods. The resulting concentrations are all well below the site-specific cleanup goals.

1.0 Introduction

This report summarizes the technical review of analytical results generated in support of the soil sampling event at the former DuPont Works Site in DuPont, Washington. The criteria applied for this review are consistent with analytical method protocols, in conjunction with the laboratory-established control limits. In cases where specific guidance was not available from either of these sources, the data have been evaluated using professional judgement consistent with industry standards. The review included evaluation of chain-of-custody, holding time and summary information for method blanks (to assess contamination), sample duplicates (to assess precision), and matrix spike recoveries (to assess matrix effect).

The report is arranged by method; within each method section is a sub-section addressing each data quality indicator. In situations where all applicable criteria were met, it will be stated. If criteria were not met, the non-compliance, qualifier and associated samples are listed. Appendices A and B list qualifier definitions and acronyms, respectively. Appendix C, the data summary table, displays all sample results, as well as qualifiers and descriptors that may apply. Appendix D includes a summary of all qualified data, by analysis type. All samples collected are identified in Table 1. If applicable, any discrepancies or deficiencies associated with sampling and analysis can be found in Table 2. Rejected data, if applicable, are identified in Table 3 (Appendix E). All remaining tables (Appendix E) list all qualified data by data quality indicator and analysis type as well as results that did not meet specific screening levels.

The laboratory electronic data format (EDF) for this project was used to generate this report. In many cases abbreviations are used from the EDF; refer to the acronyms (Appendix B) for an explanation of abbreviations. When discrepancies between the hardcopy data and the EDF are found, the EDF has been modified to reflect values from the hardcopy, unless the hardcopy is found to be in error. Results used to generate this report are deemed to be accurate.

I certify that all data validation criteria described above were assessed, and any qualifications made to the data were in accordance with the cited reference documents.

2.0 Executive Summary

One hundred eighty-four soil samples were collected by Weyerhaeuser, Inc. from June 25, 2002 to July 24, 2002 at the Former DuPont Works Site in DuPont, Washington. Samples were submitted to Severn Trent Laboratories (STL) in Tacoma, Washington within the same day of collection. Samples were analyzed for total lead and arsenic by either EPA Method 6010 (ICP) or EPA Method 6020 (ICP/MS).

The laboratory reports only included sample results, method blanks, matrix spike results and matrix duplicate results. Laboratory control samples, prep and analysis logs, and calibration information were not reported. All requested analyses were performed by the laboratory. Cooler receipt forms were not generated, therefore sample condition upon arrival to the laboratory could not be evaluated.

Sample 01-SS-[75-R79C300]-D3-050 listed on the chain-of-custody in sample delivery group 106905 was listed on the analytical report and associated electronic data deliverable (EDD) as 01-SS[75-R76C300]-D3-050, and sample 02-SS-[75-R81C41-2]-D1-050 listed on the chain-of-custody in sample delivery group 107174 was listed on the analytical report and associated EDD as 02-SS[75-R81C4]-D1-050. Sample IDs were changed to the identification used on the chain-of-custodies.

Acceptable accuracy and/or precision was exhibited in matrix spikes and sample duplicates. Acceptable precision was exhibited in the field duplicates indicating a homogeneous matrix. No data were qualified indicating the absence of matrix interference.

3.0 Total Metals (As & Pb only) 6010/6020

The following number of samples were prepared and analyzed by the listed methods:

Laboratory STL

# of Samples	Matrix	Analysis Metho	Reporting Units
120	Soil	SW6020	mg/kg
64	Soil	SW6010	mg/kg

Samples analyzed by these methods are identified in Table 1.

3.1 Holding Time

All samples were analyzed within the required technical holding time.

3.2 Blanks

Method blanks were analyzed at the minimum required frequency. All target analytes were reported as nondetected in all cases.

Field blanks were not collected for analysis by these methods.

3.3 Matrix Spike/Matrix Spike Duplicates

Matrix spikes were analyzed at the required frequency. All recoveries were within the method control limits of 75-125%.

3.4 Sample Duplicates

Laboratory sample duplicates were also analyzed. Precision between the primary and duplicate sample results was acceptable in all cases.

3.5 Quantitation Limits

The practical quantitation limits (PQLs) achieved by the laboratory were acceptable relative to the estimated quantitation limits (EQL) suggested by these methods in SW846 for soil matrix samples. Project-required report limits were not specified for this project. All samples were reported as detected.

3.6 Field Duplicates

Eight sets of field duplicate samples were collected for analysis by this method as shown below.

3.7 Overall Assessment

No data quality deficiencies were found. All data generated by these methods should be considered useable as reported.

Appendix A

Qualifier Definitions

B	The sample result is less than 5 or 10 times (for common laboratory contaminants) the associated blank contamination.
U	The analyte was analyzed for, but was not detected above the reported quantitation limit.
UJ	The analyte was not detected above the reported quantitation limit. However, the reported quantitation is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J/none	Sample results for the analyte are estimated for positive results; results reported below the quantitation limit are not qualified (high bias).
J/UJ	Sample results for the analyte are estimated for both positive results and results reported below the quantitation limit (low bias).
R/UR	The sample results are rejected for both positive results and results reported below the quantitation limit due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Appendix B

Acronyms

CRQL	Contract Required Quantitation Limit
H	High Bias
L	Low Bias
LCL	Lower Control Limit
LCS/LCSD	Laboratory Control Sample/Laboratory Control Sample Duplicate
MB	Method Blank
MDL	Method Detection Limit
MS/MSD	Matrix Spike/Matrix Spike Duplicate
N	No Bias Determined
NA	Not Applicable
NE	Not Established
NR	Not Reported
PQL	Practical Quantitation Limit
Q	Qualifier
QA	Quality Assurance
QC	Quality Control
RPD	Relative Percent Difference
RRL	Required Reporting Limit
RSD	Relative Standard Deviation
RTHT	Required Technical Holding Time
SD	Sample Duplicate
STL	Severn Trent Laboratories
SW-846	EPA Test Methods for Evaluating Solid Waste
UCL	Upper Control Limit

Appendix C

Data Summary Table

QUALIFIER REASON CODES

a - The analyte was found in the method blank

a- - Negative drift observed in instrument calibration blanks

b - Surrogate spike recovery outside control limits

c - Matrix Spike/Matrix Spike Duplicate (MS/MSD) recovery outside control limits

d - Laboratory Control Sample (LCS) recovery outside control limits

e - Holding time exceeded

f - MS/LCS sample duplicate failed precision criteria

h - Second column results indicate that the environmental results were not confirmed

i - Instrument Calibration outside control limits

k - The analyte was found in the field blank

m - Numerical value between the MDL and PQL

n - Field duplicate precision problem

o - Result reported exceeds calibration range

p - Sample was not properly collected, preserved or shipped

s - Internal Standard outside control limits

t - Sample temperature outside acceptance criteria

(Note: Where multiple qualifiers have been applied the first qualifier corresponds to the first reason code)

TPH	Total petroleum hydrocarbons
UST	Underground Storage Tank
WAC	Washington Administrative Code
Ecology	Washington State Department of Ecology
Weyerhaeuser	Weyerhaeuser Company

Section 1 – INTRODUCTION

This report presents the Washington State Department of Ecology's (Ecology) proposed cleanup action for the Former DuPont Works Site (Site), located in southwestern Pierce County, within the City of DuPont, Washington (Figure 1-1). This Cleanup Action Plan (CAP) is required as part of the site cleanup process under the Model Toxics Control Act (MTCA), Chapter 70.105D Revised Code of Washington (RCW), implemented by Ecology. The cleanup action decision is based on the Remedial Investigation (RI), Risk Assessment (RA) and Feasibility Study (FS) completed by the Weyerhaeuser Company (Weyerhaeuser) and E.I. duPont de Nemours and Company, Inc. (DuPont) and other relevant documents in the administrative record.

This CAP includes the following:

- A summary of the history of operations, ownership, and disposal activities at the Site (Section 2).
- A summary of the efforts completed to date as Interim Source Removal (ISR) Actions (Section 2).
- A summary of the nature and extent of contamination as presented in the RI (Section 3).
- Cleanup and/or remediation levels for the Site, as presented in the RA, that are protective of human health and the environment (Section 4).
- Determination of the need for additional remedial actions (Section 5).
- Decision of which remedial alternatives, as presented in the FS, will be required for each cleanup unit (Section 6).

1.1 DECLARATION

Ecology has selected the remedies described in Section 6 because they will be protective of human health and the environment. Furthermore, the selected remedies are consistent with the preference of the State of Washington as stated in RCW 70.105D.030(1)(b) for permanent solutions. In addition, the chosen remedies were selected in accordance with the requirements identified in MTCA (Washington Administrative Code (WAC) 173-340-360 – Selection of Cleanup Actions).

1.2 APPLICABILITY

Cleanup and remediation levels specified in this CAP are applicable only to the Site. They were developed as a part of an overall remediation process under Ecology oversight, and, comply with MTCA.

1.3 ADMINISTRATIVE RECORD

The documents used to make the decisions discussed in this CAP are on file in the administrative record for the Site. Major documents are listed in the reference section. The entire administrative record for the Site is available for public review by appointment at Ecology's Southwest Regional Office, located at 300 Desmond Drive, Lacey, WA 98504-7775. Please call (360) 407-6365 to set up an appointment.

1.4 PREVIOUS WORK

This CAP presents a brief description and history of the Site. Results from applicable Site studies and reports are summarized to provide background information pertinent to the CAP. These studies and reports include:

- URS and PIONEER Technologies Corporation. 2003. Remedial Investigation, Former DuPont Works Site, DuPont Washington.
- PIONEER Technologies Corporation. 2003. Human Health and Ecological Risk Assessment for the Former DuPont Works Site, DuPont, Washington.
- West Shore Corporation NW. 2003. Feasibility Study for the Former DuPont Works Site, DuPont, Washington.

Figure 1-1

Section 2 – SITE BACKGROUND

This Section summarizes the Site history, including the chronological history of the investigations, and ISR activities that have taken place at the Site, and describes the physical characteristics of the Site.

2.1 PROPERTY HISTORY

The Site property was originally used by Native Americans. In the 1830s, Europeans settled in the area and built Fort Nisqually, which was located in the northern portion of the Site. DuPont acquired the property in 1906 and constructed an explosives plant and the historical Village of DuPont as a company town for plant workers. DuPont continued to manufacture explosives at the Site until the mid 1970s, when it sold the property and adjacent areas to Weyerhaeuser. Weyerhaeuser still owns the Site. Activities at the Site during its operation and decommissioning resulted in the accumulation of residual chemicals in soils Site-wide and in groundwater.

2.2 SITE INVESTIGATIONS

Actions taken at the Site subsequent to the manufacturing shutdown in 1976 include the following:

- In 1985, Weyerhaeuser initiated studies to determine whether hazardous substances were present.
- In 1986, a Phase I Site Survey and Review was conducted to identify areas on Site that may be of environmental concern.
- In 1986, soil contamination was first documented and reported to Ecology.
- In 1987, a Phase II Site Characterization study was performed, which characterized the type, concentration, and distribution of constituents at 38 areas on the Site.
- In 1989, a Baseline Human Health Risk Assessment was performed using results of the Phase II survey.
- In 1991, Weyerhaeuser and DuPont signed a Consent Decree (No. 91 2 01703 1) with Ecology. This required the Companies to complete an RI, RA, and FS for the Site. The Site was divided into two main areas: Parcel 1 (approximately 636 acres); and Parcel 2 (approximately 205 acres).
- In 1994 and 1995, Draft RI, RA, and FS reports were submitted to Ecology.
- In 1996, based on the result of interim source removal actions, Ecology approved a Cleanup Action Plan (CAP) for Parcel 2 that provided for no further remediation activities except for the institutional controls to maintain the industrial use of Parcel 2.
- In 1997, Parcel 2 was deleted from the Consent Decree, and the deed restriction requiring institutional controls to maintain the industrial use was recorded in the Pierce County Auditor's Office.

Between 1990 and 2001, while studies and negotiations were ongoing, Weyerhaeuser and DuPont undertook interim source removal actions to clean up soil and/or debris at the Site, in accordance with MTCA and the Consent Decree.

2.3 INTERIM REMEDIAL ACTIONS

Interim source removals have been conducted at the Site between 1990 and 2001 to remove soil and/or debris from specific areas. These ISR activities were undertaken in specific areas referred to as RI areas, which were defined according to historical manufacturing and production operations at the Site. During the ISR activities soil at many of the pre-RI and RI sample locations was removed and therefore data collected previously from those locations are no longer representative of current Site conditions. Removal activities were summarized in a series of ISR memoranda (and in the RI) and have included:

- RI Areas 5 and 6 drum, soil, and debris removal.
- RI Area 8 pipeline, tank, and soil removal.

- Sympathetic detonations (RI Area 18).
- Dinitrotoluene-impacted soil removal (RI Areas 10, 18, 25, and 31).
- Lead and miscellaneous debris removal (RI Areas 18/1/2/3/4, 19C, 24, 30, 31, 35, and 36, and Maintenance Buildings).
- Mercury-impacted soil removal (RI Area 39).
- Underground storage tank (UST) removals (RI Areas 20A and 20B, 38, and 39).
- Site-wide lead and arsenic hot spot removal including RI Area LR-68.
- Lead and arsenic impacted soil removal [Foundation and Narrow Gauge Railroad (NGRR)].
- Lead and arsenic impacted soil removal (Sand and Topsoil Laydown Areas).

2.4 RI/RA/FS

In 2002, revised drafts of the RI, RA and FS were submitted to Ecology. These documents present the basis for the decisions selected for the Site and presented in this Report. A brief description of the contents of each of these reports is presented below.

2.4.1 RI

The purpose of the RI was to collect, develop, and evaluate sufficient information regarding the Site to enable completion of the RA and FS. The RI characterized the nature and extent of contamination in the context of past activities at the Site. The RI also presented the analytical data which represents current conditions at the Site (i.e. post-ISR) grouped by RI area.

2.4.2 RA

In contrast to the RI, the RA evaluated Site conditions in relation to future land uses at the Site. The RA identified default soil cleanup concentrations and presented the methods used to derive Site-specific soil concentrations that are protective of human health and ecological receptors based on future land use. These cleanup levels (CLs) and remediation levels (RLs) were compared to Site chemical concentrations in order to identify which areas required additional evaluation in the FS.

2.4.3 FS

The FS evaluated over 50 different remedial technologies or groupings of technologies to identify the alternatives with the highest potential to meet the remedial action objectives (RAOs). The FS divided the Site into Remediation Units (RUs) based upon land use type, or unique physical characteristics, and developed a preferred alternative for each RU. The FS provides the information necessary for Ecology to evaluate and select the remedial alternative appropriate for the Site.

2.5 PHYSICAL SITE CHARACTERISTICS

2.5.1 Topography

The Site is situated on a glacial outwash plain that slopes gently to the west, toward Puget Sound. The significant features of relief across the Site are numerous glacial kettles (depressions), the east-west trending valley of Sequalitchew Creek, a small kettle lake in the southern portion of the Former Production Area (Old Fort Lake), and the steep bluff bordering Burlington Northern Railroad property. The elevation across the Site generally ranges from 200 to 225 feet above mean sea level (msl), except within the kettles, which are at an elevation of approximately 150 feet msl. Before ISR activities began, the Site was generally forested with intermittent clearings associated with the former production activities.

2.5.2 Geology

The four major stratigraphic units beneath the Site include Steilacoom Gravels, Vashon Till, the Olympia Beds/Possession Drift/Whidbey Formation/Double Bluff Drift sequence (DBD-OB) (formerly known as the Kitsap Formation) (Borden and Troost. 2001) and the Salmon Springs Glaciation (formerly known as the Salmon Springs Formation). Each of these units is described below.

Steilacoom Gravels comprise the surficial soils of the Site and extend to a depth of 300 feet. The Steilacoom Gravels consist of brown and gray stratified sands and gravels, with cobbles and occasional zones of siltier sand. The Steilacoom Gravels were deposited during retreat of the final (Vashon) glaciation in high-energy meltwater channels, which originated in a proglacial lake located in the present-day Puyallup River valley to the east.

The Vashon Till consists of a high density, high silt content till that makes it a weak aquitard upon which perched water has been observed. The Vashon Till is underlain by the Vashon Advance Outwash, which was deposited by glacial rivers or streams during advance of the Vashon glaciation. The Advance Outwash becomes finer-grained with depth, typical of advance outwash deposition.

The DBD-OB sequence is a fine-grained, interglacial deposit approximately 70 to 100 feet thick, and very heterogeneous regionally. The DBD-OB sequence is present below the Site but does not extend west of a line about 2,500 feet inland from Puget Sound.

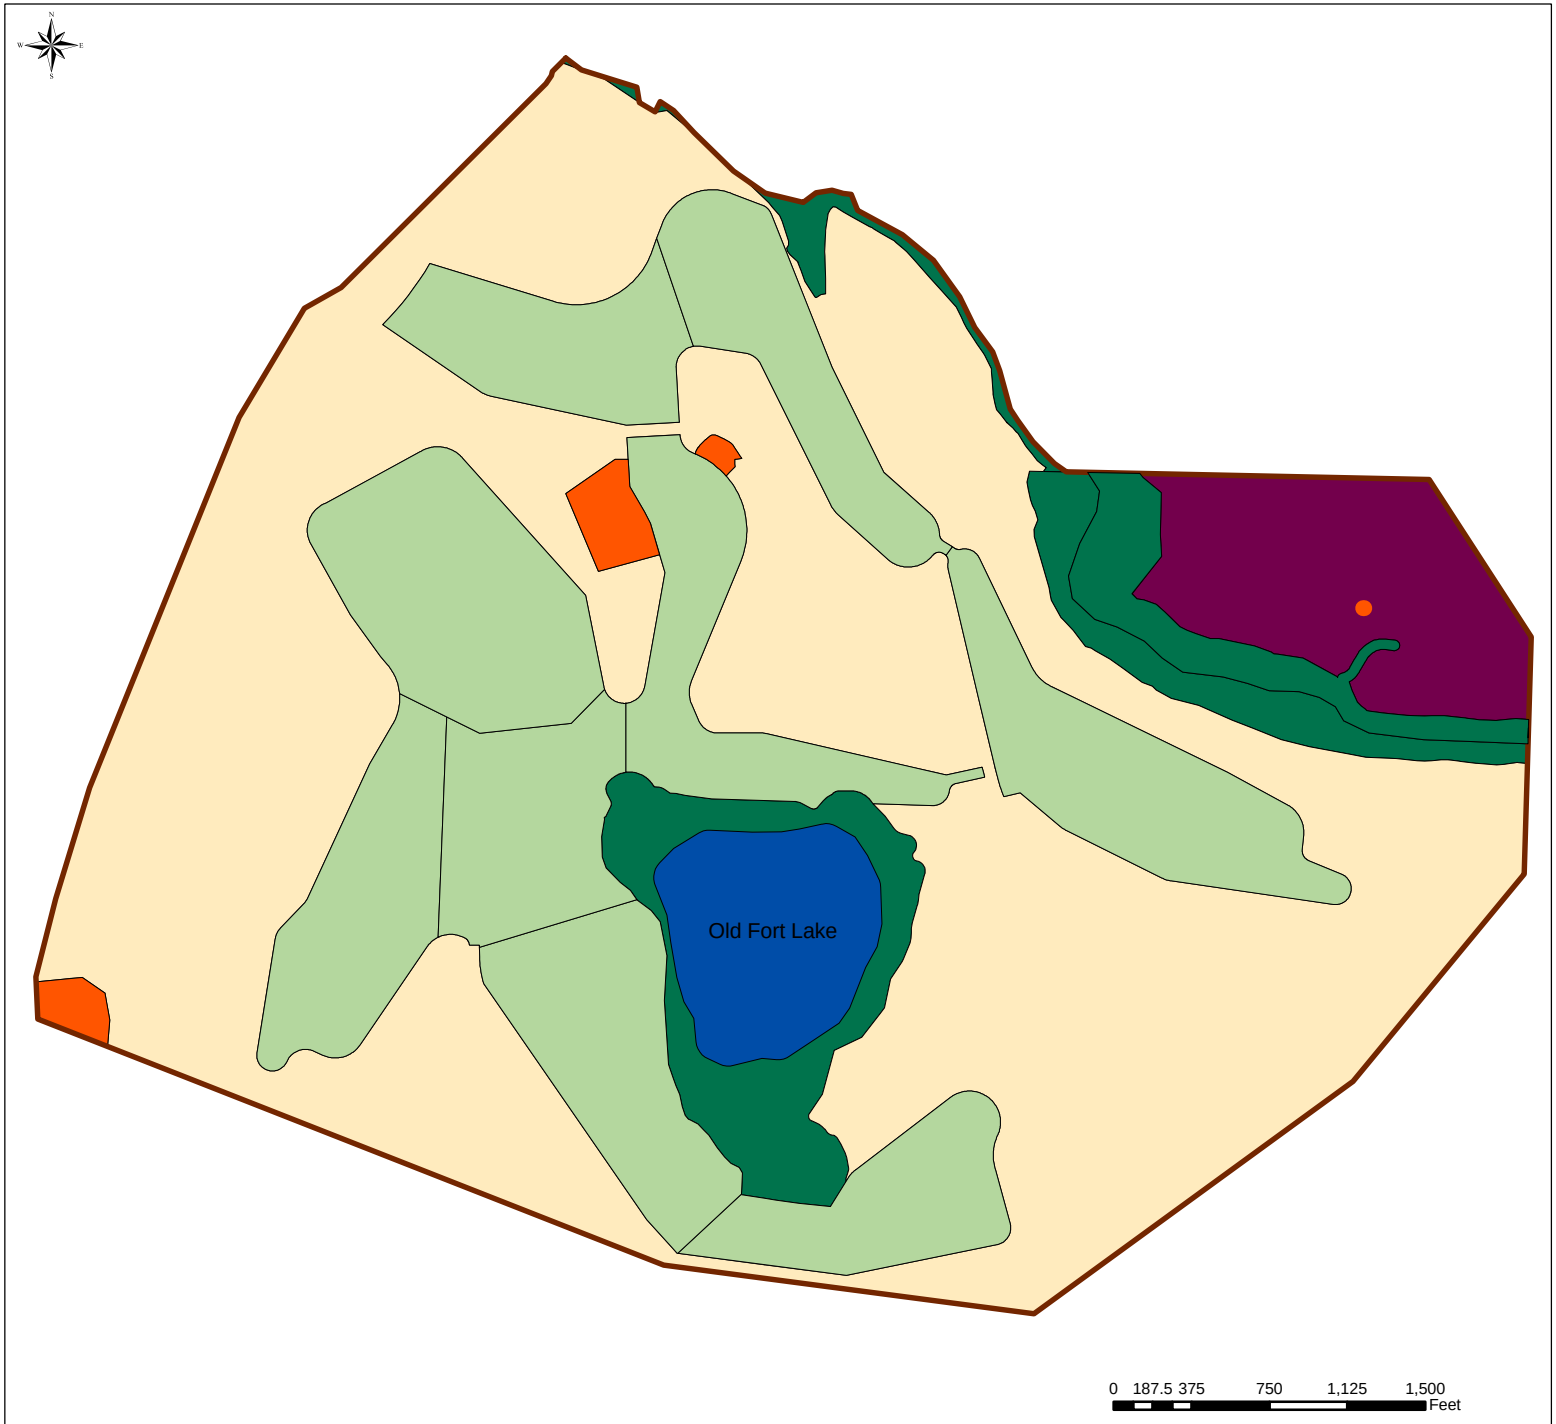
The Salmon Springs Glaciation was deposited in the glacial period preceding the DBD-OB sequence interglacial. Regional information indicates that the formation is 70 to 120 feet thick and contains zones of organic silt and till. The Sea Level Aquifer is a regionally extensive aquifer that occurs within the Salmon Springs Glaciation.

2.5.3 Hydrogeology

Two aquifers are present beneath the Site—the shallow Water Table Aquifer (20 to 105 feet below ground surface (BGS)) and the deeper Sea Level Aquifer (160 to 215 feet BGS). Across most of the Site, the relatively impermeable beds within the DBD-OB sequence (Aquitard) restricts vertical flow of groundwater and separates the Water Table Aquifer from the deeper Sea Level Aquifer. However, the Aquitard is absent west of the "Cutoff", which is located 500 to 2,500 feet east of Puget Sound, and roughly parallel to the shoreline. The "Cutoff" is the western extent of the Water Table Aquifer and is where the Sea Level Aquifer becomes unconfined (west of the "Cutoff"). Groundwater in the Water Table Aquifer flows toward the west-northwest, with local discharge via springs to upper Sequalitchew Creek. At the "Cutoff", groundwater from the Water Table Aquifer mixes with groundwater in the Sea Level Aquifer. Groundwater in the Sea Level Aquifer flows toward the west-northwest and discharges west of the "Cutoff" as seeps to Puget Sound.

2.6 FUTURE LAND USE

Based on a restrictive covenant, and in accordance with the Final Environmental Impact Statement, future use of the Site will include commercial, golf course, historical, industrial, and open space uses. Commercial use will include development of offices and retail businesses, and will comprise approximately 334 acres of the Site. Most of the soil in commercial areas will be covered by buildings, parking lots, and roads. The remaining soil will be either professionally landscaped or covered with sidewalks. A golf course will cover approximately 187 acres of the Site. Historical areas on the Site include the 1833 Hudson's Bay Fort, the Shell Midden Site, the 404 Burial Site, and the Methodist Mission site (the location of the monument is presented in Figure 2-1, but the size and actual location are unknown). In total, the 1833 Fort, Shell Midden, and the 404 site comprise approximately 4 acres of the Site. Weyerhaeuser, Weyerhaeuser Real Estate Company, City of DuPont, The Nisqually Point Defense Fund, Committee for the Preservation of the Nisqually Mission Historical Site, The Nisqually Delta Association and the DuPont Historical Society have a Memorandum of Agreement (MOA, 2000) that develops a framework for the establishment of a National Historic District along the banks of Sequalitchew Creek. This MOA is outside the scope of this cleanup project and will come into effect after the cleanup is completed. Industrial use may include activities ranging from mining gravel to development of light industrial facilities. The area proposed for industrial use is north of Sequalitchew Creek and comprises approximately 36 acres of the Site. Open space use, which will occur in four areas of the Site, will encompass a total area of approximately 73 acres. The location of each of these future use areas is presented in Figure 2-1.



Legend

- Industrial
- Historical
- Golf Course
- Old Fort Lake
- Open Space
- Parcel One
- Commercial

Notes

Historical location in the Industrial area is the Methodist Mission Marker. Actual location of the mission is unknown.

Future Land Use at the Site

Former DuPont Works Site
May 2003

Figure 2-1

Section 3 – NATURE AND EXTENT OF CONTAMINATION

This Section summarizes the nature and extent of contamination for each medium at the Site including soil, groundwater, surface water, and freshwater sediment. The potential risks associated with affected soils as well as the future land use for the Site are also presented.

3.1 SOIL QUALITY

3.1.1 Current Conditions

Site soil contamination occurs as two distinct categories; lead and arsenic impacted soils, and isolated small occurrences of total petroleum hydrocarbons (TPH), mercury, di and trinitrotoluenes (DNT/TNT), and/or benzo(a)pyrene impacted soils. This second group, referred to as Miscellaneous Small Remediation Units or MSUs throughout this Report, represents less than 1% of the total volume of contaminated soils.

3.1.2 Lateral and Vertical Extent

Lead and Arsenic Impacted Soils
Lead contamination was detected Site-wide. Arsenic contamination was generally detected within 25 feet of the former NGRR track beds but can occur in other discrete areas of the Site. The vertical extent of those chemicals was generally confined to a depth of less than 1 foot BGS in all areas except where acid was discharged, drywell locations, some production-related foundations, and disposal areas. The vertical extent was generally limited to a depth of less than 10 feet BGS in these areas.

Miscellaneous Small Units
The lateral extent of MSU soils was generally limited to production building foundations and waste disposal areas. The vertical extent of chemicals was generally confined to a depth of less than 1 foot BGS in all areas except where acid was discharged, drywell locations, some production-related foundations, and disposal areas. The vertical extent was generally limited to a depth of less than 10 feet in these areas. Debris painted with lead-based paint occur in soils throughout the Site. The majority of these occurrences is limited to production foundations and waste disposal areas but can occur in other discrete areas of the Site.

3.2 GROUNDWATER QUALITY

3.2.1 DNT Data for Site Groundwater

DNT is the only chemical that is of potential concern in groundwater. All other chemicals are either below levels of concern, were not detected, or are below background concentrations. Data from 34 rounds of combined pre-RI and RI groundwater sampling at 30 well locations indicate that low DNT concentrations have been consistently detected in 6 of 30 Site groundwater monitoring locations.

3.2.2 DNT Data for Groundwater Discharging via Seeps to Puget Sound

Site groundwater is discharging to the intertidal area of Puget Sound. The seep groundwater discharge is naturally saline due to saltwater intrusion, which disqualifies these seeps as drinking water sources in accordance with MTCA (the locations are also submerged at high tide). Two visible and accessible locations, Seep 1 and Seep 2, were sampled and total DNT has ranged from nondetect to 0.27 µg/L in the 25 samples collected from SEEP 1. DNT was not detected in SEEP 2. All detected DNT concentrations at SEEP 1 are at least 33 times lower than the surface water protective concentration of 9.1 µg/L.

3.2.3 Other Chemicals

In 1988, nitrate was detected in three Site monitoring wells. Because one of the monitoring wells is located along the eastern (upgradient) edge of the Site, off-Site sources of nitrate (such as animal pasturing) are possible. All three wells have had relatively low nitrate concentrations since 1988. Total cPAH concentrations in groundwater have all been low. With the exception of naturally occurring aluminum concentrations (also detected in background groundwater samples), all other dissolved metals were detected at low concentrations.

3.3 SURFACE WATER QUALITY

Three surface water bodies—Puget Sound, Sequalitchew Creek, and Old Fort Lake—occur within or adjacent to the Site. Puget Sound is a large saltwater body west of the Consent Decree area. Puget Sound directly or indirectly receives all groundwater and surface water discharge from the Site. Sequalitchew Creek is a perennial stream that originates in Sequalitchew Lake east of the Site and discharges into Puget Sound. In the dry season, the upper and lower reaches of the creek within the Site are dry. Old Fort Lake is a small glacial kettle lake that has no inlet or outlet. The lake is fed by groundwater from the Water Table Aquifer, and the lake level is an expression of the Water Table Aquifer.

Of the wide range of chemicals sampled for in Site surface water, only dissolved lead and dissolved copper were detected at elevated concentrations in one or more samples collected from Old Fort Lake and Sequalitchew Creek. Dissolved copper was the only chemical with confirmed elevated detections. Dissolved lead was detected infrequently at marginally elevated concentrations in both Old Fort Lake and Sequalitchew Creek. None of the lead detections were confirmed in preceding or subsequent sampling rounds. In addition, the concentrations of dissolved copper and lead detected in on-Site surface water are within the range of background concentrations detected in an area background (upstream) sampling location in Sequalitchew Creek (SW-4). Concentrations of dissolved copper and lead detected in on-Site surface water are within the range of background concentrations detected in other regional rivers and streams in Pierce County.

Based on these data, Ecology provided verbal agreement that No Further Action was required for surface water at the Site (pending the submittal of a summary of the data), indicating that chemicals detected in Site surface water do not require cleanup or any further action (Ecology 1996).

3.4 FRESHWATER SEDIMENT

Of the wide range of chemicals for which freshwater sediment samples were analyzed, no chemicals were detected at elevated concentrations. Lead was detected in Old Fort Lake sediments but at relatively low concentrations. Detected concentrations of metals were comparable to available background sediment data for the Puget Sound region.

Based on these data, Ecology provided verbal agreement that No Further Action was required for freshwater sediment at the Site (pending the submittal of a summary of the data), indicating that chemicals detected in Site freshwater sediment do not require cleanup or any further action (Ecology 1996).

Section 4 – SOIL INDICATOR CHEMICALS AND CLEANUP STANDARDS

This Section identifies the indicator chemicals and summarizes the Site-specific cleanup and remediation levels. MTCA requires the establishment of cleanup standards for individual sites. Cleanup standards consist of cleanup or remediation levels and points of compliance. Cleanup and remediation levels (CLs and RLs, respectively) determine the concentration at which a chemical does not pose a threat to human health or the environment. Material that exceeds a CL or RL is addressed through a remedy that prevents exposure to the material. Points of compliance represent the locations on the Site where CLs or RLs must be met.

4.1 RISKS TO HUMAN HEALTH AND THE ENVIRONMENT

Risks to human health and the environment are associated with potential exposure to residual chemicals in soil and debris present at the Site. Residual chemicals are those chemicals that remain in the soil, after the explosives manufacturing facility was decommissioned and after ISRs. Future users of the Site may be exposed via incidental soil ingestion. Ecological receptors may be exposed via ingestion of soil, plants, or soil biota from the areas where there are residual chemicals in soil.

4.2 SELECTION OF SOIL INDICATOR CHEMICALS

MTCA defines the criteria used to determine whether a chemical should be retained as an indicator chemical for the Site. When defining CLs or RLs at a site contaminated with several hazardous chemicals, Ecology may eliminate from consideration those contaminants that contribute a small percentage of the overall risk to human health and the environment. WAC 173-340-703(2) provides that a chemical may be eliminated from further consideration based on:

- The frequency of detection. If a compound is detected in 5% or less of samples analyzed, it may be appropriate to eliminate it;
- The concentration of the chemical. Chemicals with concentrations marginally above their cleanup standards may not be important in consideration of overall hazard and risk;
- The toxicity of the chemical. It may be suitable to delete chemicals of low toxicity;
- Environmental fate. Chemicals that readily degrade in the environment may not be of importance to overall hazard or risk. Conversely, those with highly-toxic degradation products should be included in an analysis of overall hazard and risk;
- The natural background levels of the chemical. MTCA regulates risks due to chemicals found at contaminated waste sites. The risks caused by chemicals at background concentrations are not addressed by MTCA;
- The mobility and potential for exposure to the chemical. Chemicals may be eliminated if the values for these factors are low.

A preliminary list of indicator chemicals was identified for the Site by eliminating from consideration those chemicals that were not detected in any sample. Following this screening step, there were 38 detected chemicals in surface soil and 52 detected chemicals in subsurface soil. A second screening step was performed in which the maximum detected concentration for each chemical was compared to the most conservative (i.e., the lowest) soil CLs and screening concentrations presented in MTCA for human and ecological receptors. Following this screening step, there were 18 indicator chemicals identified for surface soil, 20 indicator chemicals identified for subsurface soil, and 3 COPCs identified for subsurface soil greater than 15 feet BGS at the Site.

The RA evaluated all of the indicator chemicals to determine which chemicals posed unacceptable risks. The RA (see PIONEER 2003) identified the following chemicals as being of concern:

- Lead – Site wide.
- Arsenic – Site wide.

- TPH (Bunker C and non-Bunker C) – Four locations on-Site.
- Mercury – Five locations on-Site.
- TNT – Five locations on-Site.
- Benzo(a)pyrene – One location on-Site.
- Aldrin – One location on-Site.

The CLs or RLs that were developed in the RA for each of these chemicals is presented in the following sections.

4.3 OVERVIEW OF CLEANUP, SCREENING, AND REMEDIATION LEVELS

CLs, screening levels, and RLs were used to assess potential impacts to human health and the environment at the Site. CLs specified in MTCA are concentrations that are protective of humans for specific exposure scenarios (i.e., industrial land use and unrestricted future land use) (WAC 173-340-200). To supplement these MTCA table values, Ecology has approved Site-specific CLs for a select group of chemicals (including a Site-specific CL for arsenic in soil based on the area background concentration). In addition, Ecology performed an evaluation of the Site and identified a screening concentration for lead to evaluate the potential for terrestrial ecological impacts.

RLs are Site-specific levels based on protection of human health that are developed using exposure assumptions and other media-specific factors that reflect future Site conditions. RLs are calculated using human health risk assessment procedures and Site-specific information, as specified in WAC 173-340-708. In order to apply RLs institutional controls (such as deed restrictions) or engineering controls (such as a cap) are implemented for properties with residual contamination to ensure that the exposure conditions assumed in the derivation of these levels are maintained at the Site in the future.

4.4 SITE CLEANUP, SCREENING, AND REMEDIATION LEVELS

The RI documents the presence of contamination in soil and groundwater at the Site. CLs or RLs that have been developed for each of these media are presented below and summarized in Table 4-1.

4.4.1 Soil Cleanup Levels

CLs for soil are published by Ecology, and are default values that can be used at any site. These default CLs were applied to the industrial area located north of Sequalitchew Creek. These levels assume adult workers would be exposed to hazardous chemicals through incidental soil ingestion, and were calculated in accordance with WAC 173-340-745. Another CL used at the Site was 2,000 mg/kg for TPH (non-bunker C), which was obtained from the MTCA Method A Table, in WAC 173-340-900. In addition, Site-specific CLs for mercury, TPH (bunker C), total DNT, and TNT were approved for use at the Site by Ecology.

An area background soil concentration was determined and used to develop a CL for arsenic per WAC 173-340-709. As part of the RI investigation, soil samples were collected outside of the Consent Decree boundary to define the "Site Area Background" level of arsenic. As stipulated in WAC 173-340-709, twenty soil samples were collected to statistically establish area background levels. Based on the results of these samples, the Site area background concentration for arsenic is 32 mg/kg. This value represents the 90^{th} percentile value of the distribution of the background samples.

4.4.2 Ecological Soil Screening Concentration for Lead

Ecology has performed an evaluation of the Site and determined that lead is the indicator chemical for potential terrestrial ecological impacts. As part of this evaluation, Ecology determined that based on Site-specific information the potential species groups of concern included ground-feeding birds and herbivorous small mammals. The resulting soil lead screening level identified by Ecology is intended to be protective of wildlife, including birds and small mammals.

4.4.3 Soil Remediation Levels

The equations used to calculate RLs for all chemicals except lead were obtained from WAC 173-340-740. Soil RLs were calculated using these equations, considering the potential reasonable maximum exposure (RME) for humans under each future land use. For lead, EPA and Ecology have chosen to evaluate the potential adverse health effects

using a physiologically-based model. The model currently used by EPA for establishing lead RLs in non-residential areas is the Adult Lead Model (EPA, 1996). Using this model, Site-specific RLs were developed for golf course worker, commercial worker, and industrial worker scenarios. A hybrid approach using both the Adult Lead Model and the child Integrated Exposure Uptake Biokinetic Model for Lead (IEUBK), was used to derive a RL for open space areas.

4.4.4 Groundwater Cleanup Level for DNT

The groundwater CL for DNT was calculated in accordance with MTCA Method B, WAC 173-340-720. This default value was calculated based on the assumption that someone is living at the Site and their drinking water is obtained from groundwater.

4.4.5 Summary of Cleanup and Remediation Levels

Table 4-1 presents the soil cleanup, screening, and remediation levels for each land use and applicable media. These values were used in the RA and FS to evaluate the effectiveness of remedial actions for each chemical and RU.

4.5 POINT OF COMPLIANCE

The MTCA Cleanup Regulation defines the point of compliance as the point or points where CLs or RLs shall be attained (WAC 173-340-200). Once CLs or RLs are met at the point of compliance, the Site is no longer considered a threat to human health or the environment.

4.5.1 Soil Points of Compliance

For soil CLs and RLs the point of compliance is established in soils throughout the Site. The actual points of compliance will be located on the Site-wide grid nodes that are 75 feet apart. In instances where there are MSUs located 0 to 1 foot BGS, the point of compliance will be a 50 x 50 foot area that will be centered on or around each MSU area. The point of compliance for MSUs at a depth greater than 1 foot BGS will be 15 x 15 foot boxes and samples will be collected from each sidewall and the bottom of the excavation.

4.5.2 Groundwater Point of Compliance

For groundwater, each well is a point of compliance.

Table 4-1 – Soil and Groundwater Cleanup, Screening, and Remediation Levels for each Land Use

Chemical	Commercial and Golf Course Cleanup and Remediation Levels (mg/kg)	Golf Course Cap Remediation Levels (mg/kg)	Historical and Open Space Cleanup and Remediation Levels (mg/kg)	Industrial Cleanup and Remediation Levels (mg/kg)	Groundwater Screening Concentration (ug/L)
Explosives					
2,4,6-Trinitrotoluene	1.75[1.2]	1.75[1,2]	1.75[1]	1.75[1]	NA
DNT	3.0[3]	3.0[3]	3.0[3]	3.0[3]	0.13
Petroleum Hydrocarbons					
TPH (418.1) (Bunker C)	7,600[4]	7,600[4]	7,600[4]	7,600[4]	NA
TPH (418.1) (heavy oil, non-Bunker C)	2,000[5]	2,000[5]	2,000[5]	2,000[5]	NA
Inorganics					
Arsenic	60[6,7]	530[6,7]	32[8]	90[9]	NA
Lead	118[10]	4,100[6]	118[10]	1,000[11]	NA
Mercury	24[6]	24[6]	24[6]	24[6]	NA
PAHs					
Benzo(a)Pyrene	12.6[7]	109[7]	0.71[7]	18[10]	NA
Pesticides/PCBs					
Aldrin	5[6]	47[6]	0.3[6]	7.7[9]	NA

Notes:
[1] Soil concentration protective of groundwater approved by Ecology.
[2] Value is a cleanup level.
[3] Soil concentration for DNT (2,4-DNT plus 2,6-DNT) protective of human health and groundwater approved by Ecology.
[4] Ecology agreement for TPH that originated as Bunker C fuel. One Area has TPH that did not originate from Bunker C fuel. Those TPH data were compared to the MTCA Table A value of 2,000 mg/kg for heavy oils.
[5] MTCA Method A value for heavy oil.
[6] Based on Site-specific exposure factors approved by Ecology.
[7] Value is a remediation level.
[8] Based on Site-specific background concentration approved by Ecology.
[9] Calculated using MTCA Method C parameters.
[10] Ecological screening concentration.
[11] MTCA default value used for Parcel 2.

Section 5 – SELECTION OF A CLEANUP ACTION

5.1 REMEDIAL ACTION OBJECTIVES

Remedial Action Objectives (RAOs) are statements describing the actions necessary to protect human health and the environment through eliminating, reducing, or otherwise controlling risks posed through each exposure pathway and migration route. They are developed considering the appropriate CLs or RLs for each indicator chemical, the characteristics of the contaminated medium, the characteristics of the chemicals present, the migration and exposure pathways, the potential receptor points and other relevant regulations.

Soil and groundwater are the contaminated media of concern at the Site. People may be exposed to contaminated soil via ingestion while ecological receptors may be exposed via ingestion of soil, plants, and soil biota. Due to existing deed restrictions eliminating residential development, the most likely potentially exposed populations would be on-Site workers and older children who will have access to open space areas.

Given these potentially exposed populations and exposure pathways, the RAOs for the Site center around the prevention or minimization of exposure of humans and ecological receptors to impacted soils, but include:

- Achieving CLs or RLs that will be protective of human health and the environment; and
- Compliance with chemical-, location-, and action-specific Applicable or Relevant, and Appropriate Requirements (ARARs).

5.2 APPLICABLE, RELEVANT AND APPROPRIATE REQUIREMENTS

MTCA requires that all cleanup actions comply with applicable state and federal law, and further states that the term 'applicable state and federal laws' shall include legally applicable requirements and those requirements that the department determines are 'relevant and appropriate requirements' (WAC 173-340-710(1)). This section discusses applicable state and federal law, relevant and appropriate requirements, and local permitting requirements, which were considered in the FS and were of primary importance in selecting cleanup requirements in this CAP. If other requirements are identified at a later date, they will be applied to the cleanup actions at that time.

MTCA provides an exemption from the procedural requirements of several state laws, and from any laws authorizing local government permits or approvals for remedial actions (RCW 70.105D.090). Substantive requirements must be met. The substantive requirements currently known are incorporated into this CAP. If further additional substantive requirements are identified, the necessary steps to incorporate them will be taken. The procedural requirements of the following state laws are exempted:

- Chapter 70.94 RCW, Washington Clean Air Act;
- Chapter 70.95 RCW, Solid Waste Management, Reduction, and Recycling;
- Chapter 70.105 RCW, Hazardous Waste Management;
- Chapter 75.20 RCW, Construction Projects in State Waters;
- Chapter 90.48 RCW, Water Pollution Control; and
- Chapter 90.58 RCW, Shoreline Management Act of 1971.

WAC 173-340-710(4) sets forth the criteria that Ecology evaluates when determining whether certain requirements are relevant and appropriate for a cleanup. Those criteria are as follows:

(a) Whether the purpose for which the statute or regulations under which the requirement was created is similar to the purpose of the cleanup action;

(b) Whether the media regulated or affected by the requirement is similar to the media contaminated or affected at the site;

(c) Whether the hazardous chemical regulated by the requirement is similar to the hazardous chemical found at the site;

(d) Whether the entities or interests affected, or protected, by the requirement are similar to the entities or interests affected by the site;

(e) Whether the actions, or activities, regulated by the requirement are similar to the cleanup action contemplated at the site;

(f) Whether any variance, waiver, or exemption to the requirements are available for the circumstances of the site;

(g) Whether the type of place regulated is similar to the site;

(h) Whether the type and size of structure or site regulated is similar to the type and size of structure, or site, affected by the release or contemplated by the cleanup action; and

(i) Whether any consideration of use or potential use of affected resources in the requirement is similar to the use, or potential use, of the resources affected by the site, or contemplated cleanup action.

The following lists present the state and federal laws that contain the ARARs that apply to the cleanup action for the Former DuPont Works Site.

Potential CLs and Chemical-Specific ARARs

- The Model Toxics Control Act Chapter 173-340 WAC.

Potential Location-Specific Requirements

- Washington State Shoreline Management Act (Chapter 90.58 RCW; Chapters 173-18, 173-22, and 173-27 WAC).
- Pierce County Shoreline Management Use Regulation (Title 20).
- Pierce County Development Regulations—Critical Areas (Title 18E).
- Washington State Hydraulic Projects Approval (Chapters 75.20.100 Through 75.20.160 RCW; Chapter 220-110 WAC).
- The Fish and Wildlife Coordination Act.
- Endangered Species Act (16 USC 1531 et seq.; 50 CFR Parts 17, 225, and 402).
- Native American Graves Protection and Repatriation Act (25 USC 3001 Through 3013; 43 CFR Part 10) and Washington's Indian Graves and Records Law (Chapter 27.44 RCW).
- Archaeological Resources Protection Act (16 USC 470aa et seq.; 43 CFR Part 7).

Potential Action-Specific Requirements

- Washington Dangerous Waste Regulations (Chapter 173-303 WAC).
- Solid Waste Management Act (Chapter 70.95 RCW; Chapter 173-304 and 173-351 WAC).
- Water Quality Standards for Surface Waters of the State of Washington (Chapters 90.48 and 90.54 RCW; Chapter 173-201A WAC).
- Federal, State, and Local Air Quality Protection Programs.
- Department of Transportation Hazardous Materials Regulations (40 CFR Parts 171 Through 180).
- Occupational Safety and Health Act (29 CFR 1910).

- Washington State Water Well Construction Act (Chapter 18.104 RCW; Chapter 173-160 WAC).

5.3 SOIL CLEANUP ACTION ALTERNATIVE EVALUATION CRITERIA

Cleanup alternatives designed to meet RAOs were evaluated as part of the FS for the Site. The following criteria were used to screen technologies and processes to determine if the alternatives selected represent those that are permanent to the maximum extent practicable as defined by WAC 173-340-360 (3)(b).

5.3.1 Effectiveness

Effectiveness involves those criteria that evaluate the state of development of the technology, the ability to protect human health and the environment, and identifies potential negative impacts associated with the technology. Under this heading are the following MTCA criteria:

- Protectiveness: This evaluation considers the degree of protection each technology provides to human health and the environment, the extent to which reductions in risk, toxicity, and/or mobility are expected to be achieved, the time required to reduce risk and obtain cleanup standards, the off-Site and on-Site risks resulting from the implementation of the alternative, and the degree of improvement of the overall environmental quality.
- Permanence: This evaluation considers the degree to which the alternative permanently reduces the toxicity, mobilization or volume of the contaminants. This evaluation considers the materials treated, quantity of material treated, degree of toxicity, mobility, and volume reduction, degree to which the treatment is irreversible, and residuals type and quantity.
- Long Term Effectiveness: This evaluation considers the effectiveness of the process during the time when contaminant concentrations remain on-Site that are greater than CLs or RLs, the magnitude of risk with the alternative in place, and the adequacy and reliability of any Site controls.
- Management of Short Term Risks: This evaluation considers the effectiveness of the process in dealing with the potential impacts to human health and the environment during the implementation phase.
- Consideration of Public Concerns: This evaluation considers community concerns associated with the alternative, and how those concerns will be addressed.

5.3.2 Implementability

Implementability involves the technical and administrative feasibility of constructing, operating, and maintaining a particular remediation technology. Technical implementability has already been used in the preliminary screening. At this stage, the emphasis is placed on the institutional aspects of implementability, such as the ability to obtain the necessary permits, the availability of treatment, storage, and disposal services, and the availability of necessary equipment and skilled workers to implement the technology.

5.3.3 Cost

The cost for remediation work includes such items as installation and operation of process equipment, excavation, and disposal fees. The cost analysis is made on the basis of engineering judgment, and each process is evaluated as to whether costs are high, medium, or low relative to other process options in the same technology category.

5.4 GROUNDWATER CLEANUP ACTION ALTERNATIVES EVALUATION

Dinitrotoluene (DNT) has been detected in groundwater below the Site at concentrations above drinking water standards but consistently below the MTCA Method B value. Two alternatives where evaluated in the FS for the remediation of groundwater. They were Active Groundwater Treatment and Natural Restoration.

5.5 REMEDIAL ALTERNATIVES EVALUATED AT THE SITE FOR SOIL

The FS evaluated over 50 different technologies or combinations of technologies using the criteria presented in Secton 5.3 and recommended the following four remedial alternatives for detailed analysis. These alternatives where judged to be appropriate for large-scale applications (ranging from greater than 2 acres in size to total Site remediation) only.

- No Action;
- On-Site Deposition with Cap (i.e., highly durable, impermeable, engineered material) and Cover (i.e., clean soil layer that may include gravel layer);
- Off-Site Disposal at a Landfill; and
- Wet Screening with On-Site Deposition with Cap and Cover and Disposal of the Residual Soils at a Landfill.

The FS determined that there were five alternatives that should be further evaluated for small-scale applications (less than 2 acres in size or 5,000 cubic yards in volume). In addition to the No Action alternative, which may have limited applications and small isolated occurrences of chemicals that were not either used or generated as part of the manufacturing activities of decommissioning of the buildings at the Site, the four primary remedial alternatives (to be used on a small-scale basis) considered in the detailed analysis were as follows:

- Cap;
- Cover;
- Cap/Cover; and
- Off-Site Disposal at a Landfill.

The FS performed a detailed analysis of these remedial alternatives and recommended on-Site Deposition with Cap and Cover as the preferred alternative for large-scale applications and a combination of the above alternatives for small scale applications:

5.6 EVALUATION OF THE RETAINED CLEANUP ACTION ALTERNATIVES

The retained alternatives were evaluated using the following six criteria:

- Protection of Human Health and the Environment;
- Compliance with Cleanup Standards;
- Compliance with Applicable State and Federal Laws;
- Provision for Compliance Monitoring;
- Use of Permanent Solutions to the Maximum Extent Practicable; and
- Provision of a Reasonable Restoration Time Frame

The results of the evaluation for each criterion is presented below.

5.6.1 Protective of Human Health and the Environment

All alternatives, except No Action, protect human health and the environment. Ingestion of contaminated soil by on-Site workers and ingestion of soil, plants, or soil biota by ecological receptors are the primary pathways of concern. By removing the contaminated soils from the Site or covering them with a cap/cover system, these pathways are either eliminated or controlled. Institutional controls will prevent disruption to the cap/cover and thereby prevent exposure to contaminated soils. No Action does not meet cleanup standards and, thus, does not meet this threshold criterion.

5.6.2 Compliance with Cleanup Standards

All preferred alternatives, except No Action, achieve cleanup standards through either off-Site disposal or on-Site containment actions. No action does not meet cleanup standards and, thus, does not meet this threshold criterion.

5.6.3 Compliance with Applicable State and Federal Laws

All the retained alternatives comply with applicable state and federal laws as identified above, except No Action.

5.6.4 Provision for Compliance Monitoring

All alternatives could address these requirements by providing a program for compliance monitoring. A compliance monitoring plan, for groundwater, has been operational for the Site since 1989, will be updated as needed, and will be continued until CLs are met.

5.6.5 Use of Permanent Solutions to the Maximum Extent Practicable

To determine whether a cleanup action uses permanent solutions to the maximum extent practicable, the disproportionate cost analysis specified in the regulation was used (WAC 173-340-360(3)(e)). The analysis compared the costs and benefits of the cleanup action alternatives and requires the consideration of several factors. Costs are disproportionate to the benefits if the incremental costs of the alternative over that of a lower cost alternative exceed the incremental degree of benefits achieved by the alternative over that of the lower cost alternative. Based on the analysis and information completed in the FS, it has been determined that preferred alternative (On-Site Deposition with a Cap/Cover) in comparison to the other alternatives for large scale applications uses permanent solutions to the maximum extent practicable.

5.6.6 Provision of a Reasonable Restoration Time Frame

WAC 173-340-360(4) describes the specific requirements and procedures for determining whether a cleanup action provides for a reasonable restoration time frame, as required under subsection (2)(b)(ii). The factors that are used to determine whether a cleanup action provides a reasonable restoration time frame are set forth in WAC 173-340-360(4)(b). On-Site Deposition with a Cap/Cover has the shortest time frame of those retained for final analysis in the FS.

5.7 PREFERRED ALTERNATIVE FOR LARGE SCALE APPLICATIONS

Based on the above analysis, On-Site Deposition with Cap/Cover is the preferred alternative, followed by Wet Screening with On-Site Deposition, with Cap and Cover, and Disposal of the Residual Soils at a Landfill. Off-Site Disposal at a Landfill is the high cost alternative. No action has a low cost but does not meet cleanup standards and, thus, cannot be used except, possibly, in special circumstances, e.g., areas of ecological sensitivity.

5.8 PREFERRED ALTERNATIVE FOR SMALL SCALE APPLICATIONS

Like the FS, this CAP did not consider cost in the evaluation of alternatives for small scale applications. As such, Cap/Cover and Excavation, and Off-Site Disposal at a Landfill were selected as two of the three proposed preferred alternatives. On-Site Deposition with Cap/Cover was added as the third preferred alternative after further consideration. Capping could have limited application and No Action could be considered in areas of ecological sensitivity and in areas of small isolated occurrences of chemicals that were not either used or generated as part of the manufacturing activities of decommissioning of the buildings at the Site.

5.9 PREFERRED ALTERNATIVE FOR GROUNDWATER

Natural Restoration was selected as the preferred altervative for groundwater remediation. Active Groundwater Treatment was not selected since its cost would be substantial and disproportionate to the degree of risk reduction achieved.

Section 6 – PROPOSED CLEANUP ACTION DECISION

The proposed cleanup action for the Site for the different RUs is presented below. The different RUs are identified in Figure 6-1.

6.1 PROPOSED CLEANUP ACTION - LARGE SCALE APPLICATIONS

6.1.1 Remediation Units CM-1 through CM-8 and GC-1 through GC-9

Decision: Based on the analysis summarized in Section 5, the preferred alternative (On-Site Deposition with Cap/Cover) has been selected as the proposed cleanup action for these RUs.

Justification: The preferred alternative meets each of the threshold requirements and uses permanent solutions to the maximum extent practicable. The incremental costs of the other retained alternatives are disproportionate to their incremental benefits. The cost of the preferred alternative is less than the other alternatives and provides a similar level of protection for human health and the environment. The cap/cover system will reduce potential exposure routes and limit the migration of contaminants. The preferred alternative provides a reasonable restoration time frame and addresses public concerns.

6.1.2 Remediation Unit CM-09

Decision: Based upon the information presented in the RA, the No Action alternative has been selected as the proposed cleanup action for this RU.

Justification: Based upon the information presented in the RA, CM-09 will be in compliance with MTCA three-fold statistical criteria once isolated "hot spot" locations (MSU-29 and MSU-30) have been remediated. See Figure 6-2 for the location of these MSUs.

6.1.3 Remediation Units OS-01, OS-02 NOC, OS-03 SOC and OS-04

Decision: Based upon the information presented in the RA, the No Action alternative has been selected as the proposed cleanup action for these RUs. The location of the four open space RUs are presented in Figure 6-1.

Justification: Based upon the information presented in the RA, OS-01, OS-02 NOC, and OS-03 SOC will be in compliance with MTCA three-fold statistical criteria once isolated MSU locations (MSU-98 through 106) have been remediated. See Figure 6-2 for the location of these MSUs.

The OS-4 RU is the open space surrounding Old Fort Lake. There are no lead exceedances, but there are four locations that have arsenic concentrations marginally above the area background concentration of 32 mg/kg.

No Action is proposed for these RUs due to the special ecological sensitivity of the area. These RUs represent environmentally sensitive areas that contain a surface water body and steep slopes. As such, excavation in these areas would likely cause slope stability and sedimentation problems which could result in undue harm to these water bodies. Ecology has completed visual inspections of these RUs and has found diverse and abundant plant and wildlife communities. These factors have led to the determination that the greatest net environmental benefit would result from no remediation in these areas. No Action would cause less long-term harm to the local ecology in these RUs than any of the active remediation alternatives. This determination is supported by the public's strong desire to protect these sensitive areas.

6.2 DESCRIPTION OF PROPOSED CLEANUP ACTION - LARGE SCALE APPLICATIONS

6.2.1 Excavation

RUs that were not incompliance with the 3-fold criteria will be excavated to a depth of 1 foot.

6.2.2 Soil Excavation Methods

Excavation of soils not in compliance with Site-specific RLs for lead and arsenic would occur by one of the following methods. All excavation work done within the first three feet of the current ground surface will be monitored by trained archeologists to determine if cultural or archeological artifacts are present. If any artifacts are found they will be treated in the manner described in the Cultural Resource Protection Plan.

Scraping
The majority of the shallow soils (up to 1.0 foot deep) will be excavated using self-loading pan scrapers. This method would be used on those areas within Parcel 1 that are not historical or open space RUs. Some selected excavation could occur within the golf course areas. The general scraping process would be:

- Phase I - The upper six inches of soil would be removed, using a self-loading pan scraper.
- Phase II - The remaining six inches of soil would be graded into a windrow and picked up by the pan scraper. GPS will be used to confirm the initial depth, followed by a complete survey to confirm the depth excavated.

Other Excavation
In those areas not accessible to the pan scrapers (because of topography or other reasons), an excavator will be used to selectively excavate the soil in six to eight inch lifts until the desired depth of 1 foot is met. The excavated soil will be loaded into off-road haul trucks and transported to the PAs for placement. Direct pushing of soils into the PA is possible from areas adjacent to PAs GPS will be used to confirm the initial depth, followed by a complete survey to confirm the depth excavated.

All of the material excavated would be placed in the PAs within the golf course areas and rough-graded.

6.2.3 Cap Construction

A golf course will be constructed on the Site and will serve as engineered cover (cap) for contaminated soils and, if necessary, debris. The majority of this material will be moved from the commercial land use areas in Parcel 1 and consolidated in roughly 90 acres of the approximately 180-acre golf course footprint. These 90 acres would constitute the PAs. Only soils and debris that contain contaminant concentrations equal to or less than the golf course RLs would be placed in the PAs. Each PA would be capped with 18 inches of clean soil by one of the two methods listed below. This cap would be placed on any areas with in-situ contaminant concentrations (if not excavated) less than the golf course RL but greater than the Site-specific commercial RL.

Method One
Six inches of clean soil will be placed over 12 inches of pit run gravel. In this process, the gravel would act as an exposure barrier to ecological receptors. The six inches of clean soil would act as an additional exposure barrier to individuals most likely to be exposed—the golf course worker, who, on occasion, may find it necessary to install drainage ditches or repair irrigation pipes.

Method Two
Eighteen inches of “pit run” soil will be placed over a geotextile. In this case, the 18 inches of soil would act as the human exposure barrier and the geotextile will act as the ecological exposure barrier.

6.2.4 Haul/Stockpile

Excavated soil will be transported directly to future golf course placement areas (PAs) for deposition or transported to a central area and stockpiled in preparation for treatment or disposal.

6.2.5 Verification Sampling and Analysis

Verification soil samples will be collected from excavated areas and analyzed. Analytical results will be evaluated to determine compliance. If soil remaining in the excavation does not meet Site RLs or, if applicable, CLs, additional excavation and verification sampling and analysis will be performed.

6.3 PROPOSED CLEANUP ACTION – SMALL-SCALE APPLICATIONS

6.3.1 Miscellaneous Small Remediation Units: MSU-1, 2, 5, 6, 9, 11, 12, and 18-28

Decision: Based upon the information presented in the RA and FS, the Excavation and Off-Site Disposal at a Landfill alternative has been selected as the proposed cleanup action for these RUs. See Figure 6-2 for the location of these MSUs.

Justification: These MSUs contain isolated occurrences of a single contaminant in soil and represent a small in-place volume. This alternative meets each of the threshold requirements. Furthermore, since it would be costly to perform secondary treatment on soils, the preferred alternative uses permanent solutions to the maximum extent practicable. The incremental costs of the other retained alternatives are disproportionate to their incremental benefits. Due to the small volume of soil involved, this alternative provides a reasonable restoration time frame and addresses public concerns.

6.3.2 Miscellaneous Small Remediation Units: MSU-122-132

Decision: Based upon the information presented in the RA and FS, the Excavation and Off-Site Disposal at a Landfill alternative has been selected as the proposed cleanup action for these RUs. See Figure 6-2 for the location of these MSUs.

Justification: These MSUs contain isolated occurrences of chemicals that were not either used or generated as part of the manufacturing activities or decommissioning of the buildings at the Site. No action would be appropriate for small occurrences of cadmium since this contaminant has not been detected in groundwater, occurs in very low concentrations, has an average/mean concentration that is below the CL, has a low number of exceedances (less than 5%) of the CL in comparison to the number of detections and/or samples collected, and have no known source associated with activities at the Site.

6.3.3 Miscellaneous Small Remediation Units: MSU-4, 8, 7, 10, 14-16, 76 and 87

Decision: Based upon the information presented in the RA and FS, the Excavation and Off-Site Disposal at a Landfill alternative has been selected as the proposed cleanup action for these RUs. See Figure 6-2 for the location of these MSUs.

Justification: These MSUs contain occurrences of a similar mixture of contaminants (e.g., TPH mixture, nitroaromatic explosive compound mixture, etc.) in soil and represent a small in-place volume. This alternative meets each of the threshold requirements. Furthermore, since it would be costly to perform secondary treatment on soils, the preferred alternative uses permanent solutions to the maximum extent practicable. The incremental costs of the other retained alternatives are disproportionate to their incremental benefits. Due to the small volume of soil involved, this alternative provides a reasonable restoration time frame and addresses public concerns.

6.3.4 Miscellaneous Small Remediation Units: MSU-3, 13, 29-68, 70-75, 77-86, 88-94, and 96-106

Decision: Based on the analysis summarized above, the preferred alternative (On-Site Deposition and Cap/Cover) has been selected as the proposed cleanup action for these RUs. See Figure 6-2 for the location of these MSUs.

Justification: These MSUs represent locations in open space as well as locations outside PAs greater than 1 foot below ground surface where there are arsenic and/or lead exceedances. On-Site Deposition with Cap/Cover (including excavation) meets each of the threshold requirements. Furthermore, the preferred alternative uses permanent solutions to the maximum extent practicable. The incremental costs of the other retained alternatives are disproportionate to their incremental benefits. The cost of the preferred alternative is less than the other alternatives and provides a similar level of protection for human health and the environment. The cap/cover system will

reduce potential exposure routes and limit the migration of contaminants. The preferred alternative provides a reasonable restoration time frame and addresses public concerns.

6.3.5 Miscellaneous Small Remediation Units: MSU-133-138

Decision: Based upon the information presented in the RA and FS, the Cap/Cover alternative has been selected as the proposed cleanup action for these RUs. See Figure 6-2 for the location of this MSU.

Justification: This is the historical location known as the Fort Nisqually Cemetary (PI404). It is an area of special cultural significance. The application of a cap/cover is appropriate in this MSU where an exposure barrier is desired. This technology is appropriate for in-situ soils in these areas if the performance standards listed in Section 6.4 are met. Cap/Cover will be required over this entire MSU.

6.3.6 Miscellaneous Small Remediation Units: MSU-69 and 108-120

Decision: Based upon the information presented in the RA and FS, both the Cap/Cover and On-Site Deposition with Cap/Cover (including excavation) alternatives have been selected as the proposed cleanup action for these RUs. See Figure 6-2 for the location of these MSUs.

Justification: These are areas of special cultural significance known as the 1883 Fort Nisqually and the South Midden Site. Since archeological excavation is possible in these areas, a cap/cover will not be appropriate unless areas of the MSU can be isolated from further work and an exposure barrier is desired. No known contaminant concentrations in these areas exceed the remediation levels established for placement under the proposed golf course. As such, at a minimum, the following two alternatives will be applied at each sample location within these MSUs that exceeds the Site-specific RLs:

- Cap/Cover for 10 feet in each direction or the edge of the MSU, whichever is nearest the sample location. Cap/Cover is only possible in those areas of the MSU where institutional controls are in place to eliminate the potential for future excavation; or
- Excavation and On-Site Deposition with Cap/Cover for 25 feet in each direction or the edge of the MSU, whichever is nearest the sample location.

6.3.7 Miscellaneous Small Remediation Units: NGRR-10

Decision: Based upon the information presented in the RA and FS, the Cap/Cover alternative has been selected as the proposed cleanup action for this MSU. See Figure 6-3 for the location of this MSU.

Justification: This MSU is located within Sequalitchew Creek Canyon, an environmentally sensitive area. Asphalt capping (with a gravel sub-base) would create an effective exposure barrier within the track bed. This cap would be necessary across the entire track bed ranging from where the track bed encounters the natural slope of the canyon in both the uphill and downhill directions. The limited use of this technology would meet cleanup standards, be protective long-term (with active maintenance) and is cost effective.

6.3.8 Miscellaneous Small Remediation Units: NGRR-01-09, 11-16, and 19-46

Decision: Based on the analysis summarized above, the preferred alternative (On-Site Deposition and Cap/Cover) has been selected as the proposed cleanup action for these RUs. See Figure 6-3 for the location of these MSUs.

Justification: These MSUs represent sections of former NGRR track bed that are still in place. These areas were not remediated as part of previous ISRs because the Forest Practices Act Permit had not been granted at that time. On-Site Deposition with Cap/Cover (including excavation) meets each of the threshold requirements. Furthermore, the preferred alternative uses permanent solutions to the maximum extent practicable. The incremental costs of the other retained alternatives are disproportionate to their incremental benefits. The cost of the preferred alternative is less than the other alternatives and provides a similar level of protection for human health and the environment.

The cap/cover system will reduce potential exposure routes and limit the migration of contaminants. The preferred alternative provides a reasonable restoration time frame and addresses public concerns.

6.3.9 Miscellaneous Small Remediation Units: "Hot Spots"

Decision: These RUs are represented by soils with contaminant concentrations greater than golf course RLs that are discovered during the implementation of any cleanup action. Excavation and Off-Site Disposal at a Landfill alternative has been selected as the proposed cleanup action for these RUs.

Justification: Off-Site Disposal at a Landfill is required for any soils with contaminant concentrations greater than golf course RLs. This alternative meets each of the threshold requirements. Furthermore, since it would be costly to perform secondary treatment on soils, the preferred alternative uses permanent solutions to the maximum extent practicable. The incremental costs of the other retained alternatives are disproportionate to their incremental benefits. Due to the small volume of soil involved, this alternative provides a reasonable restoration time frame and addresses public concerns.

6.3.10 Miscellaneous Small Remediation Units: MSUs-1-4, 8-16, 18, 20, 25-32, and 36

Decision: These RUs are occurrences of in-place debris and stockpiled material. The regulatory status of this debris is unknown. As such, the Excavation and Off-Site Disposal at a Landfill alternative has been selected as the proposed cleanup action unless the debris passes the analytical testing process (for debris) listed in Section 6.4. If the debris passes the performance criteria it can either be placed in the golf course PAs or, if below regulatory limits, treated as solid waste. See Figure 6-4 for the location of these MSUs.

Justification: Off-Site disposal is required for any debris with contaminant concentrations greater than golf course RLs. This alternative meets each of the threshold requirements. Furthermore, since it would be costly to perform secondary treatment on debris, the preferred alternative uses permanent solutions to the maximum extent practicable. The incremental costs of the other retained alternatives are disproportionate to their incremental benefits. Due to the small volume of debris involved, this alternative provides a reasonable restoration time frame and addresses public concerns.

6.4 DESCRIPTION OF PROPOSED CLEANUP ACTION - SMALL SCALE APPLICATIONS

6.4.1 Off-Site Disposal at a Landfill

Under this alternative soils above Site-specific CLs for non-lead and non-arsenic contaminated soils would be excavated, loaded into 30-ton trucks and hauled to and disposed of at an off-Site landfill. Additional excavation would be required if either conformational or RI testing showed that they contained contaminant concentrations greater than CLs or RLs. The excavated soils would be stockpiled, sampled, and transported to an approved off-Site disposal facility.

6.4.2 Cap/Cover

This alternative involves the installation of an engineered cap/cover 18 inches in thickness using one of the two methods listed below. This cap would be placed on any golf course land use areas with in-situ contaminant concentrations less than the golf course remediation level but greater than the Site-specific commercial remediation level.

- **Method One:** Six inches of clean soil would be placed over 12 inches of pit run gravel. In this process, the gravel would act as an exposure barrier to ecological receptors. The six inches of clean soil would act as an additional exposure barrier to humans.
- **Method Two:** Eighteen inches of "pit run" soil would be placed over a geotextile. In this case, the 18 inches of soil would act as the human health exposure barrier and the geotextile will act as the ecological exposure barrier.

6.4.3 On-Site Deposition with Cap/Cover

In general, this alternative would involve the mass excavation of the existing soils containing contaminant concentrations above the CL but below the RL for a particular area, followed by the transfer, consolidation and capping of the excavated soils beneath the planned golf course. The cap would be constructed by one of the methods described in section 6.4.2.

6.4.4 Limited Use Alternatives

6.4.4.1 Capping

This alternative would involve the construction of an impermeable cap over existing soils containing contaminant concentrations above the CL but below the RL for a particular area. An example would be the use of an asphalt cap. In this case, the asphalt and sub-base would act as the human health and the ecological exposure barrier. No excavation of underlying soils would occur.

6.4.4.2 No Action

- No remediation activities would occur under this alternative.

6.5 PROPOSED CLEANUP ACTION – GROUNDWATER

Natural Restoration was selected as the preferred alternative for groundwater remediation. Active Groundwater Treatment was not selected since its cost would be substantial and disproportionate to the degree of risk reduction achieved.

6.6 PERFORMANCE STANDARDS

6.6.1 Cap Construction

The engineered cap/cover will be designed and constructed so that it acts as a protective barrier to direct contact with humans or animals. At a minimum the cap/cover will include:

Ecological Barrier: This will consist of a minimum of 12 inches of pit run gravel. This decision is based upon the determination of Ecology's Ecological Risk Specialist that there is low likelihood that soil biota will travel through this depth of gravel to get to underlying soils and on-Site observations which show that Steilacoom gravels do not support biological growth or activity. In lieu of gravels a geotextile that meets the same performance standards can be used.

Human Health Barrier: This barrier will consist of the soil necessary to make the cap/cover a minimum of 18 inches thick. If gravel is used for an ecological barrier the depth of soil cover will be no less than six inches. If geotextile is used the soil will be minimum of 18 inches thick. This decision is based upon the maximum depth in which a golf course worker is expected to excavate to make repairs to waterlines and irrigation piping.

Vegetated Areas: Additional soil will be required above the ecological and human health cap/cover in areas where vegetation will be planted. This soil will be thick enough to accommodate the root ball of any planted vegetation plus a total of four inches.

In setting these standards Ecology expects that engineering specifications will be developed during remedial design and will require approval by Ecology prior to implementation.

6.6.2 Soil Compliance Sampling

Large Application Soil Compliance Sampling
For soil CLs and RLs based on exposure via direct contact, the point of compliance is established for soils throughout the Site. Compliance verification samples will be collected on 75-foot centers after the contaminated soil has been removed. Five-point composite samples will be collected from 0 to 6 inches BGS and the area represented by the sample will be considered to be in compliance when the resulting concentrations are less than the Site- and land use-specific cleanup standards. If a sample exceeds the cleanup standards, one foot of additional soil will be excavated. No RU wide statistics will be used to evaluate compliance.

Miscellaneous Small Unit Soil Compliance Sampling

The point of compliance for surficial MSUs (i.e, 0 to 1 foot BGS) and debris areas will be 50 x 50 foot areas. One five-point composite confirmation sample (0 to 6 inches BGS) will be collected in every 50 x 50 foot area. The point of compliance for MSUs at a depth greater than one foot BGS will be 15 x 15 foot boxes and samples will be collected from each sidewall and the bottom of the excavation. The area represented by the sample will be considered to be in compliance when the resulting concentrations are less than the Site- and land use-specific cleanup standards. No MSU wide statistics will be used to evaluate compliance.

6.6.3 Groundwater Monitoring

Because the majority of detected DNT concentrations are consistently low, are not affecting the regional aquifer, are not affecting surface water, and the aquifer is not used as a drinking water source, Natural Restoration has been selected. Ecology agreed to the selection of this alternative by issuing a "No Active Remedial Action" letter for Site groundwater (Ecology 1996a).

Groundwater monitoring will be required at the Site until DNT concentrations below drinking water standards are obtained in four consecutive sampling rounds. Monitoring will discontinue after approval from Ecology. The wells that will be monitored for DNT as part of the cleanup action are monitoring wells MW-3, MW-6, MW-19, MW-22, production well W-2 (as long as it is operational), and a new monitoring well installed down gradient of RI Area 25. Seep 1 will be sampled during annual groundwater monitoring events after the surface soil mass excavation remediation work has been completed. Ecology may also require groundwater monitoring at other locations.

Groundwater monitoring and laboratory analysis shall follow the procedures outlined in the Management Plan for Remedial Investigation/Feasibility Study (Hart Crowser, 1992). Any adjustments or changes to this plan must be approved by Ecology prior to implementation. Reports shall be submitted using the same format as in the past.

The highest DNT concentration in groundwater ever detected at the Site was 3.8 ug/L in MW-27 in January of 1995. If any of the results from future groundwater sampling is greater than 3.8 ug/L Ecology will meet with Weyerhaeuser and DuPont to discuss the results.

6.6.4 Debris Evaluation

Contaminated debris occurs in two forms; lead painted metal, wood or brick, and elemental lead. Debris that is painted will be tested to determine if the paint is lead-based. If lead-based paint is present, a representative composite sample of painted debris will be collected, and sent to the Project Laboratory for analysis. The results will be reported in mg/kg.

Stockpiles or debris evaluated for lead-based paint will be designated based on the analytical results as follows:

- If the lead concentration is less than 118 mg/kg the material will be treated as fill.
- If the lead concentration is greater than 118 mg/kg but, less than 4,100 mg/kg the material will be moved to a placement area.
- If the lead concentration is greater than 4,100 mg/kg the material will be cleaned and/or disposed of off-Site.

6.7 INSTITUTIONAL CONTROLS

Institutional controls are measures undertaken to limit or prohibit activities that may interfere with the integrity of a cleanup action or result in exposure to hazardous chemicals at the Site. Such measures are required to assure both the continued protection of human health and the environment, and the integrity of the cleanup action whenever hazardous chemicals remain at the Site at concentrations that exceed the applicable CL (WAC 173-340-440(1) and (4)).

Institutional controls are a critical component of this proposed cleanup action. Residual contamination will remain on-site beneath the cap/cover. Both physical controls and legal and administrative mechanisms will be used to ensure that current and future citizens and wildlife do not come into contact with residual contamination, and that the integrity of the cap/cover containment system is maintained. Institutional controls will take the form of

restrictive covenants placed with the deed. The restrictive covenants will limit Site use with the purpose of minimizing disturbance to the cap/cover system, and will prevent any unauthorized excavation on the property.

Deed restrictions to limit Site uses will be imposed for different land uses including commercial, recreational (golf course), historical, industrial, and open space. An additional deed restriction will be required for the property inside the golf course footprint that limits this property to that sole use and places restrictions on activities that could disturb the cap/cover.

A deed restriction shall also be placed upon the Site to restrict the use of groundwater to non-potable uses only, until such time as it meets cleanup levels.

6.8 EXPECTATIONS FOR CLEANUP ACTIONS

The Site contains two surface water bodies and has large volumes of contaminated soil that are remaining on-Site. Therefore, in accordance with the expectations outlined in WAC 173-340-370, the selected cleanup action will involve the consolidation of wastes, use active measures to prevent runoff from contacting waste materials, and actively prevent releases to groundwater.

6.9 CLEANUP ACTION SCHEDULE

A schedule for the Site cleanup is presented in Figure 6-5.

6.10 FIVE YEAR REVIEW

WAC 173-340-420 states that at sites where a cleanup action requires an institutional control, a periodic review shall be completed no less frequently than every five years after the initiation of a cleanup action. Since the lead and arsenic impacted soils will remain on-Site and institutional controls will be required, five-year reviews shall take place at this Site. Groundwater monitoring data shall be reviewed until applicable cleanup requirements are met.

Prepared By:

West Shore Corporation, NW

July 2003

Preface

P.1 Introduction

These Volumes present information developed as part of the Final Remedial Investigation, Risk Assessment, and Feasibility Study (RI/RA/FS) for the Former DuPont Works Site (Site) located in DuPont, WA (See Figure P-1). These reports were stipulated in a Consent Decree, effective July 1991, between the lead agency, Washington State Department of Ecology (Ecology), and the principle responsible parties, Weyerhaeuser Company (Weyerhaeuser) and E.I. duPont de Nemours and Company, Inc. (DuPont). Per the Consent Decree, the reports were developed in accordance with the Model Toxics Control Act Cleanup Regulation (MTCA). Draft RI/RA/FS reports were completed in 1994 and 1995, submitted to Ecology, and underwent public review. The draft Final RI/RA/FS reports, presented here, have been developed to satisfy comments on the draft reports and to accurately reflect existing conditions and future land use at the Site. In addition, these reports incorporate a variety of agreements that have been reached with Ecology following completion of the draft studies in 1994 and 1995.

P.2 Property History

The Site property was originally used by Native Americans. European settlement began in 1832, when the Hudson's Bay Company established a cabin/storehouse on nearby Puget Sound at the mouth of Sequalitchew Creek, northwest of the Site (City of DuPont, 1995). In 1833, Hudson's Bay built Fort Nisqually, which was located in the northern portion of the Site. Ten years later, a new Fort Nisqually was built at a location adjacent to but outside the eastern edge of the Site.

The DuPont Company acquired the property in 1906 and constructed an explosives plant and the historical Village of DuPont as a company town for plant workers (the historical village area is located approximately 1 mile southeast of the Site). DuPont continued to manufacture explosives at the Site until the mid 1970s, when it sold the property and adjacent areas to the Weyerhaeuser Company. Weyerhaeuser and its subsidiary, Weyerhaeuser Real Estate Company (WRECO), still own the majority of the approximately 2,500 acres in the area, which they named Northwest Landing. Northwest Landing is a planned community in the City of DuPont and includes the Site. WRECO has begun to develop Northwest Landing on some of its lands within the City, but cannot develop the Site until the cleanup has been completed.

P.3 Site Regulatory History

The Site was used for the manufacture of commercial explosives from 1909 to 1976. Production of explosive material ceased and decommissioning of the buildings began in 1976, when Weyerhaeuser purchased the property from DuPont. As part of the cleanup process, asbestos was removed, salvageable materials were taken out, and structures were either burned or demolished. Actions taken at the Site subsequent to the shutdown in 1976 include the following:

- In 1985, Weyerhaeuser initiated studies to determine whether hazardous substances were present.
- In 1986, a Phase I Site Survey and Review was conducted to identify areas on Site that may be of environmental concern.
- In 1986, soil contamination was first documented and reported to Ecology.
- In 1987, a Phase II Site Characterization study was performed, which characterized the type, concentration, and distribution of constituents at 38 areas on the Site.

- In 1989, a Baseline Human Health Risk Assessment was performed using results of the Phase II survey.

- In 1991, Weyerhaeuser and DuPont signed a Consent Decree (No. 91 2 01703 1) with Ecology, where they agreed to study the Site and complete an RI, RA, and FS. The Site was divided into two main areas: Parcel 1 (approximately 636 acres); and Parcel 2 (approximately 205 acres).

- In 1994 and 1995, Draft RI, RA, and FS reports were submitted to Ecology and underwent public review.

- In 1996, based on the result of interim source removal actions, Ecology approved a Cleanup Action Plan (CAP) for Parcel 2 that provided for no further remediation activities except for the institutional controls to maintain the industrial use of Parcel 2.

- In 1997, Parcel 2 was deleted from the Consent Decree, and the deed requiring institutional controls to maintain the industrial use was recorded in the Pierce County Auditor's Office.

- Between 1990 and 2001, while studies and negotiations were ongoing, Weyerhaeuser and DuPont undertook numerous interim source removal actions to clean up soil and/or debris at the Site, in accordance with MTCA and the Consent Decree.

P.4 Description of Reports

In fulfillment of the provisions of the Consent Decree, RI, RA, and FS reports were prepared. A description of the contents of each of these reports is presented below.

- **RI** – The purpose of the RI was to collect sufficient information regarding the Site to enable the completion of the RA and FS. The RI characterizes the nature and extent of contamination based on the existing conditions at the Site. The RI Report presents the analytical data for the media that have been collected at the Site. The data are presented for each RI area, which was defined based on historical manufacturing and production operations at the Site.

- **RA** – In contrast to the RI, the RA evaluates Site conditions in relation to future land uses at the Site. The RA identifies default soil cleanup levels, and presents the methods used to derive Site-specific soil levels that are protective of human health and ecological receptors based on future land use. These cleanup levels and remediation levels are compared to Site constituent concentrations in order to identify which areas require additional evaluation in the FS.

- **FS** – The FS evaluates alternative potential cleanup methods designed to meet the remedial action objectives for the Site. The FS Report provides information for Weyerhaeuser and DuPont to recommend alternatives for remediation of selected areas, including both no action and action alternatives. Ecology will evaluate the FS and select the remedial measures it believes are appropriate. Weyerhaeuser and DuPont will complete the needed detailed design and implementation of the remedy selected by Ecology in the Cleanup Action Plan.

P.5 Report Organization and Documents

This RI/RA/FS report should be reviewed together to better understand the relationship between the Site study activities. The RI/RA/FS are interdependent Reports that are organized as follows:

Volume I – RI and Appendices
Appendix A - Field Procedures
Appendix B - Soil Quality Data
Appendix C - Groundwater, Surface Water and Freshwater Sediment Quality Data
Appendix D - Laboratory Physical Soils Testing

Appendix E - Data Quality Assessment

Volume II - RA and Appendices

Appendix A – Ecological Risk Assessment Summary
Appendix B – Evaluation Unit Sample Groupings
Appendix C – Letters and Other Documentation of Site-Specific Determinations
Appendix D – Toxicity Information For Select Constituents
Appendix E – Cleanup Level and Remediation Level Calculations
Appendix F – Summary Statistics and Comparison to Standards

Volume III - FS and Appendices

Appendix A – Description of Remediation Technologies for Soil
Appendix B – Overview of Soil Testing Procedures and Data Interpretation
Appendix C – Lead and Arsenic Soil characterization and Treatability Studies
Appendix D – Arsenic Wet Screening Study
Appendix E – Ranking of Alternatives
Appendix F – Cost Estimate for Remedial Alternatives Analyzed in Detail
Appendix G – Estimation of Minimum Soil Volume Required for Cost-Effective On-Site Treatment
Appendix H – Development of Soil Remediation Levels for the Golf Course Groundskeeper
Appendix I – Impracticability of Groundwater Remediation at the Former DuPont Works Site, DuPont, Washington.

An Executive Summary is included with each Volume.

Table of Contents

EXECUTIVE SUMMARY 1
ES.1 Introduction 1
ES.2 Background Information 1
ES.3 Interim Source Removal 1
ES.4 FS Purpose and Process 2
ES.5 Remedial Action Objectives 2
ES.6 Remediation Units and Soil Volumes 2
ES.7 Identification and Screening of Technologies 3
ES.7.1 Effectiveness 3
ES.7.2 Implementability 4
ES.7.3 Cost 4
ES.7.4 Consideration of Public Concerns 4
ES.8 Treatability Studies 4
ES.9 Detailed Analysis of Alternatives 5
ES.10 Preferred Alternatives 5

CHAPTER 1 – INTRODUCTION 1-1
1.1 Introduction 1-1
1.2 Site Description and History 1-1
1.3 Interim Source Removal 1-2
1.4 RI and RA Summary 1-2
1.4.1 Soil 1-3
1.4.2 Debris 1-3
1.4.3 Groundwater 1-3
1.5 Future Land Use 1-3
1.6 Identification of Remediation Units 1-3
1.7 FS Purpose and Report Organization 1-3
1.8 References for Chapter 1 1-13

CHAPTER 2 – REMEDIAL ACTION OBJECTIVES 2-1
2.1 Introduction 2-1
2.2 Potentially Applicable State and Federal Requirements for the FS 2-1
2.2.1 Introduction 2-1
2.2.2 Applicable State and Federal Laws 2-2
2.3 Potential Cleanup Levels and Chemical-Specific ARARs 2-2
2.4 Potential Location-Specific Requirements 2-3
2.5 Potential Action-Specific Requirements 2-4
2.6 Screening of ARARs 2-6
2.7 References for Chapter 2 2-9

CHAPTER 3 – ESTIMATED VOLUMES OF SOIL FOR REMEDIATION 3-1
3.1 Introduction 3-1
3.2 Definition of Remediation Units 3-1
3.3 Soil Volumes 3-1
3.4 Soil Volume Estimation Procedures 3-2
3.4.1 In-Place Volumes of Impacted Soil 3-3

CHAPTER 4 – IDENTIFICATION AND SCREENING OF TECHNOLOGIES 4-1
4.1 Introduction 4-1
4.2 Development of Candidate Technologies and Process Options 4-1
4.3 Technology Screening 4-2
4.3.1 Preliminary Screening 4-2
4.3.2 Technologies That Rely On Stabilization/Solidification 4-2

4.3.3 Initial Qualitative Screening 4-2
4.4 Representative Processes Selected for the Development of Alternatives 4-3

CHAPTER 5 – TREATABILITY STUDIES 5-1
5.1 Introduction 5-1
5.2 Treatability Study Objectives 5-1
5.3 Treatability Study Approach 5-2
5.3.1 Lead- and Arsenic-Impacted Soils Characterization Study - Hazen Research Inc. 5-3
5.3.2 Arsenic Wet Screening Study - Hart Crowser, Inc. 5-3
5.3.3 Arsenic Speciation Analysis - Battelle Pacific Northwest Laboratory (PNL) 5-3
5.3.4 Bench-Scale Soil Leaching Study – State University of New York, Buffalo 5-3
5.3.5 Bench-Scale Soil Leaching Study - Weyerhaeuser Analytical and Testing Services 5-4
5.4 Interpretation of Results 5-4
5.4.1 Physical Screening/Soil Washing 5-4
5.5 Conclusions and Recommendations 5-6
5.5.1 Soil Characterization 5-6
5.5.2 Volume Reduction 5-7
5.5.3 Metal Dissolution/Removal 5-7
5.6 References for Chapter 5 5-29

CHAPTER 6 – DEVELOPMENT AND SCREENING OF ALTERNATIVES 6-1
6.1 Introduction 6-1
6.2 Screening Criteria 6-1
6.2.1 Effectiveness 6-1
6.2.2 Implementability 6-2
6.2.3 Cost 6-2
6.2.4 Consideration of Public Concerns 6-2
6.2.5 Ecology Cleanup Technology Preference 6-2
6.3 Assembly of Alternatives - Groundwater 6-3
6.3.1 Description and Screening of Alternatives – Groundwater 6-3
6.4 Assembly of Alternatives - Soil 6-3
6.5 Description and Screening of Alternatives 6-4
6.5.1 No Action 6-4
6.5.2 Capping 6-5
6.5.3 Cover 6-6
6.5.4 Cap/Cover 6-7
6.5.5 On Site Deposition, Cap and Cover 6-8
6.5.6 Offsite Disposal at a Landfill 6-9
6.5.7 Wet Screening, Classification, and Disposal of the Residual Soils at a Landfill 6-10
6.5.8 Wet Screening with On Site Deposition, Cover and Cap and Disposal of the Residual Soils at a Landfill 6-11
6.5.9 Wet Screening with Stabilization and On-Site Deposition and Cap/Cover 6-12
6.5.10 Soil Washing with Wet Screening, Classification, Acid/Base Extraction, and Disposal of the Residual Soils at a Landfill 6-13
6.5.11 Soil Washing with Wet Screening, Classification, Chelant Extraction, and Disposal of the Residual Soils at a Landfill 6-14
6.6 Ranking of Alternatives 6-15
6.7 Summary of Selected Alternatives 6-15
6.8 Retained Alternatives: Large Scale Applications 6-16
6.9 Retained Alternatives: Small Scale Applications 6-16

CHAPTER 7 – DETAILED ANALYSIS OF ALTERNATIVES AND SELECTION OF PREFERRED ALTERNATIVES 7-1
7.1 Introduction 7-1
7.2 Description of the Alternatives Retained for Detailed Analysis – Large Scale Applications 7-2

7.2.1 No Action 7-2
7.2.2 Common Activities 7-2
7.2.3 On-Site Deposition, Cap and Cover 7-2
7.2.4 Off-Site Disposal at a Landfill 7-4
7.2.5 Wet Screening with On-Site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill 7-4
7.3 Comparative Detailed Analysis of Alternatives – Large Scale Applications 7-4
7.3.1 Long-Term Effectiveness and Permanence 7-5
7.3.2 Reduction of Toxicity, Mobility, and Volume 7-6
7.3.3 Short-Term Effectiveness 7-7
7.3.4 Implementability 7-9
7.3.5 Cost 7-10
7.3.6 Consideration of Public Concerns 7-11
7.4 Summary of the Detailed Analysis 7-11
7.5 Preferred Alternative for Large Scale Applications 7-11
7.6 Retained Alternatives: Small Scale Applications 7-11
7.6.1 No Action 7-11
7.6.2 Cap 7-12
7.6.3 Cover 7-12
7.6.4 Cap/Cover 7-12
7.6.5 Off-Site Disposal at a Landfill 7-13
7.7 Comparative Detailed Analysis of Alternatives – Small Scale Applications 7-13
7.7.1 Long-Term Effectiveness and Permanence 7-14
7.7.2 Reduction of Toxicity, Mobility, and Volume 7-14
7.7.3 Short-Term Effectiveness 7-15
7.7.4 Implementability 7-16
7.7.5 Cost 7-16
7.7.6 Consideration of Public Concerns 7-16
7.8 Summary of the Detailed Analysis – Small Scale Applications 7-16
7.9 Preferred Alternative for Small Scale Applications 7-16
7.10 Comparative Detailed Analysis of Alternatives – Groundwater 7-17
7.10.1 Long-Term Effectiveness and Permanence 7-17
7.10.2 Reduction of Toxicity, Mobility, and Volume 7-17
7.10.3 Short-Term Effectiveness 7-17
7.10.4 Implementability 7-18
7.10.5 Cost 7-19
7.10.6 Consideration of Public Concerns 7-19
7.11 Summary of the Detailed Analysis 7-19
7.12 Preferred Alternative for Groundwater 7-19

CHAPTER 8 – CONCEPTUAL DESIGN OF THE PREFERRED ALTERNATIVES 8-1
8.1 Introduction 8-1
8.2 Conceptual Design by Remediation Unit (Large Scale Applications) 8-1
8.3 Conceptual Design (Small-Scale Applications and Miscellaneous Small RUs) 8-3
8.4 Groundwater 8-4
8.5 Estimate of Total Site Remediation Cost 8-4
8.5.1 Cost for Remediation: Preferred Alternative – Large and Small Scale Applications 8-5
8.5.2 Cost of Groundwater Remediation 8-5
8.5.3 Cost for Total Site Remediation 8-5

ACRONYMS

Acronym	Definition
2,4-DNT	2,4-dinitrotoluene
2,6-DNT	2,6-dinitrotoluene
AKART	All known, available, and reasonable treatment
AOC	Area of Contamination
ARAR	Applicable or relevant and appropriate requirement
ASIL	Ambient source impact level
AST	Above-ground storage tank
BDAT	Best demonstrated available technology
CEC	Cation exchange capacity (see Appendix B)
CERCLA	Comprehensive Environmental Response, Compensation and Liability Act
CFR	Code of Federal Regulations
CGEST	University of Cincinnati Center for GeoEnvironmental Science and Technology
CL or RL	Statistical action level
cPAH	Carcinogenic polycyclic aromatic hydrocarbons
CSL	Cleanup Screening Level
CY	Cubic yards
DERS	DuPont Environmental Remediation Services
DNT	Dinitrotoluene
DuPont	E.I. DuPont de Nemours & Co.
Ecology	Washington State Department of Ecology
ELP	Equilibrium leaching procedure
EPA	U.S. Environmental Protection Agency
FS	Feasibility study
GANC	Generalized acid neutralization capacity (see Appendix B)
ISD	Inorganic solid debris
ISV	*In situ* vitrification
K_d	Soil: water partitioning coefficient
LDRs	Land disposal restrictions
M	Million
MANC	Metals with acid neutralization capacity (see Appendix B)
MDL	Method detection limit
mg/kg	Milligrams per kilogram
mg/L	Milligrams per liter
MMAN	Monomethylamine nitrate
MTCA	Model Toxics Control Act
NAX	Nitroaromatic explosives
NESHAPs	National Emission Standards for Hazardous Air Pollutants
NFA	No further action
NGRR	Narrow gage railroad
O&M	Operation and maintenance
ODW	EPA Office of Drinking Water
PAH	Polycyclic aromatic hydrocarbons

PH	pH (— $\log_{10}$ hydrogen ion concentration)
PNL	Pacific Northwest Laboratory
PPE	Personal Protective Equipment
PSAPCA	Puget Sound Air Pollution Control Agency
PSI	Pounds per square inch
PW	Problem waste
QA/QC	Quality assurance/quality control
QAPP	Quality Assurance Project Plan
RA	Risk assessment

EXECUTIVE SUMMARY

ES.1 Introduction

The Weyerhaeuser Company and the E.I. duPont De Nemours Company in accordance with a Consent Decree with the Washington State Department of Ecology (Ecology) conducted this Feasibility Study (FS). The Consent Decree calls for the completion of a Remedial Investigation (RI), Risk Assessment (RA), and FS for the Former DuPont Works Site (Site). The RI/RA/FS are being conducted in accordance with the Washington State Model Toxics Control Act (MTCA).

This FS report is a companion document to the RI and the RA reports. These documents should be reviewed together to better understand the relationship between the Site study activities.

The work conducted for this FS fulfills the requirements under MTCA and the RI/RA/FS Consent Decree for selecting cleanup alternatives that are protective of human health and the environment, and provide a reasonable approach to Site cleanup. The information provided in this FS will be incorporated into a Cleanup Action Plan that will outline the specific details of how the preferred alternatives will be implemented during Site cleanup.

ES.2 Background Information

The Site is located in southwestern Pierce County within the City of DuPont, Washington. Activities at the Site during its operation as an explosives manufacturing facility resulted in the accumulation of residual chemicals in soils Site wide. The highest concentrations occur in areas associated with former building foundations, in areas where manufacturing materials were disposed and along the Narrow Gauge Railroad (NGRR) tracks. The RI investigated soil, surface water, groundwater, and sediment and determined that soil was the only medium of concern. Accordingly, soil and associated debris are the only media addressed in this FS. The RA evaluated chemical concentrations in soil detected during the RI and determined that of the 213 constituents evaluated in the RA, 11 (aldrin, arsenic, benzo(a)pyrene, dinitrotoluene, copper, lead, mercury, nitrobenzene, TNT, tetrachlorethene, and TPH) were identified for remedy in the FS.

ES.3 Interim Source Removal

In accordance with MTCA (WAC 173-340-430) and the Consent Decree for the Site (Sections D and E), interim source removal has been conducted to remove soil and/or debris from 21 RI Areas of the Site between 1990 and 2001. Actions were conducted for five primary reasons:

- To minimize the potential for transport of residual constituents in soil by removing the sources, protect groundwater, and thereby minimize potential future environmental impacts;
- To remove soil and/or debris with high concentrations of constituents to improve the safety and environmental conditions at the Site;
- To remove debris (such as drums and other demolition material overlying fill and native soils) and facilitate a more complete and accurate RI;
- To minimize delays in the Site RI, RA, and FS process; and
- To prepare for the final remediation of the Site.

For each interim source removal, complete work plans were developed, reviewed by Ecology, and revised in accordance with their comments. Prior to the initiation of any interim source removal, Ecology's

approval to start was obtained. In addition, Ecology was communicated with regularly during these activities either by regular Site visits, periodic telephone calls or monthly reports.

The interim source removals are described in a series of Interim Source Removal Memoranda that are briefly summarized in the RI. The total volume of materials removed from the Site during interim source removal (through September 2001) included: approximately 60,900 tons of soil; 9,700 tons of debris; 1,540 tons of soil and debris mixtures; 4,836 drums; 69,204 gallons of liquids; and 170 cubic yards (CY) of asbestos-containing material. Materials were recycled off-Site, incinerated off-Site, or sent to an approved landfill.

Because Interim Source Removals (ISRs) have been performed, the current Site conditions have changed significantly. Therefore, this is a focused FS that addresses the residual constituents contained in soil and debris.

ES.4 FS Purpose and Process

The purpose of this FS is to present the information needed for decision makers to identify the best alternatives for Site cleanup. To do this the following steps were performed:

- Developed Remedial Action Objectives (RAOs) that protect human health and the environment and considered federal and state regulatory criteria;
- Grouped Site Areas requiring remediation into manageable units (i.e., remediation units) and estimated soil volume for each constituent in each unit;
- Developed a list of technologies that were potentially applicable to the Site and conducted initial qualitative screening of the technologies by evaluating the technology's effectiveness in meeting the criteria listed in MTCA;
- Conducted treatability studies to evaluate the selected technologies and evaluated the results;
- Developed the alternatives for Site remediation and screened them against MTCA criteria to select alternatives for detailed analysis;
- Conducted a detailed analysis of the alternatives for Site remediation; and
- Described the preferred alternative for each Site remediation unit.

ES.5 Remedial Action Objectives

RAOs were developed to comply with chemical, location, and action-specific applicable, relevant, and appropriate requirements (ARARs) and achieve cleanup standards that will be protective of human health and the environment for the Site. Cleanup and remediation levels for Site cleanup have been established through negotiation with Ecology. The derivation of these levels is discussed within the text of the RA and are based on protection of human health and the environment, and the potential risk associated with future land uses. Remediation levels (RL) were developed for four planned future land uses: open space, golf course, historical, and commercial. This FS will discuss engineering controls associated with each preferred alternative that will be used to modify the RLs discussed in the RA. These adjusted RLs have been discussed and approved by Ecology as protective of human health and the environment under the described conditions. The RAOs for the Site set the goal of the remediation, which is to prevent exposure to soils containing constituents above the cleanup levels or RLs.

ES.6 Remediation Units and Soil Volumes

The RI used historical Site information to establish 25 discrete areas of the Site. These RI areas were not used in either the RA or this FS due to the large variance in size between the RI areas and the lack of

total Site coverage. As an alternative, both the RA and this FS divided the Site into similar areas referred to as Evaluation Units (EUs) in the RA and Remediation Units (RU) in the FS. Of the 26 RUs investigated in the RA, 25 were identified for further evaluation in the FS. Forty-nine additional RUs were added to the FS to address discrete locations of contaminants (referred to as Miscellaneous Small RUs). These 150 RUs are described below, and the contamination found within them are the focus of this FS.

- **Golf Course RUs:** These RUs are those to be included within the golf course footprint. There are nine golf course RUs.

- **Open Space RUs:** These RUs are those included within the open space areas of the Site. There are four Open Space RUs.

- **Commercial Area RUs:** These RUs are those included within the areas of the Site planned for commercial use. There are nine Commercial Area RUs.

- **Historical RUs:** These three RUs make up the areas of the Site that have historic significance.

- **Miscellaneous Small RUs:** These remediation units are small, discreet units that have unique characteristics from the other large RU's. The unique characteristics can include the specific mixture of constituents in the unit, the deposition pattern of constituents in the unit, a localized "hot spot" that remained after ISR or a specific, unique location (NGRR). Due to the unique characteristics, it's more effective and practical to manage these units separately from the other larger RU's.

Soil volumes were estimated using the data collected during the RI, interim source removal activities and, in some cases, the square footage of each RU. Maps were produced showing the location and extent of constituents based on these data. The square footage of the area of the mapped locations, where the constituent concentrations do not or are not expected to meet the cleanup or remediation level, was multiplied by an estimated depth of excavation to calculate the soil volume. Soil volume estimates are based on the current Site data. The actual volume of soil to be removed during remedial action will be determined by confirmation sample data collected during remediation. The total estimated volume of in-place soil that does not meet the cleanup or remediation level prior to the selection of a remedy is approximately 1,243,000 cubic yards on an excavated basis. There is also debris on-Site (estimated at approximately 14,800 bank cubic yards) that will be managed during the cleanup action.

ES.7 Identification and Screening of Technologies

Over 50 different technologies or groupings of technologies were evaluated during this FS. Protection of human health and the environment and compliance with all RAOs (including ARARs) were established as threshold criteria since they must be met by the alternative for it to be retained for further evaluation. To expedite the screening process, only alternatives that are able to meet the threshold criteria were developed. The following MTCA criteria were used to assess the technology's ability to meet RAOs.

ES.7.1 Effectiveness

The criteria used to assess effectiveness are defined as:

Protectiveness: This evaluation considers the degree of protection each technology provides to human health and the environment.

Permanence: The degree to which the alternative permanently reduces the toxicity, mobilization or volume of the contaminants.

Long-Term Effectiveness: The evaluation of the effectiveness of the process during the time when contaminant concentrations remain on-Site that are greater than cleanup levels or remediation levels, and the magnitude of risk with the alternative in place.

Management of Short-Term Risks: This evaluation considers the effectiveness of the process dealing with the potential impacts to human health and the environment during the implementation phase.

ES.7.2 Implementability

Implementability includes both operational Implementability and administrative feasibility. Operational Implementability refers to the ability to construct and reliably operate the remediation alternative. It includes operation, maintenance, replacement, and monitoring of the technical components of an alternative. Administrative feasibility refers to the ability to obtain approvals from city/county/state officials/agencies; the availability of treatment, storage, and disposal services; and the availability of specific equipment.

ES.7.3 Cost

The cost for remediation work includes such items as installation and operation of process equipment, excavation, and disposal fees. Cost estimates were developed from a variety of sources including: technology unit costs developed by the project team, vendor information, published cost-estimating guides, and prior experience with similar technologies. Cost was not a primary screening criteria in the initial stages.

ES.7.4 Consideration of Public Concerns

MTCA requires an evaluation of any local community concerns over the alternative and how the alternative addresses those concerns.

ES.8 Treatability Studies

In some cases additional research was needed to evaluate a technology. Because the primary constituents present in Site soils are lead and arsenic, for which destruction technologies are not commercially available, treatability studies were performed to characterize the soil and to evaluate the potential for remediation by volume reduction, a primary goal of MTCA, and immobilization technologies. A comprehensive laboratory testing program was completed to determine how, and in what form, constituents are distributed in the soils and how readily different constituents in the soils can be treated using different technologies. Five combinations of treatment technologies were evaluated as part of the treatability studies:

- *Wet Screening and Classification* to evaluate the potential for separating the soil into different size fractions (physical separation) and to determine the concentrations of lead and arsenic in each size fraction;

- *Dry Screening and Classification* to evaluate the potential for separating the soil into different size fractions (physical separation) and to determine the concentrations of lead and arsenic in each size fraction;

- *Soil Washing with Acid/Base Extraction* to evaluate removal of constituents from the soil by dissolving them in a liquid and further processing that liquid to recover the extracted metals;

- *Solidification/Stabilization* to evaluate their ability to immobilize (chemically fix) concentrated metal constituents; and

- *Recycling to a Thermal Process* (e.g., a lead smelter) to determine if the finer soil fractions with high metals concentrations produced by a physical separation process could be disposed by a Thermal Process.

The primary findings of the treatability studies indicate:

- The soils can be sorted by size fractions;

- The contaminants can be immobilized by stabilization technologies;

- Use of physical separation technologies can result in a gravelly coarse fraction that can be re-used on the Site as clean soil and a fine fraction that contains metals above the remediation levels. This process will effectively decrease the volume of impacted soil requiring treatment to between 45 to 90 percent, depending on the extent of treatment; and

- The contaminants either do not leach or have very low leachability under normal environmental conditions.

ES.9 Detailed Analysis of Alternatives

The detailed analysis identifies and discusses how the remedial actions would be implemented (e.g., excavation, sampling, analysis) for each of the remedial alternatives. The treatment options are discussed relative to how they apply to the RUs. The evaluation criteria are the same as used for the screening of alternatives but a more detailed evaluation was conducted to enable selection of the preferred alternatives. In addition to the No Action alternative (no Site cleanup activities), which was retained as a baseline for comparison purposes, three other remedial alternatives were retained for detailed analysis. They were:

- **On-Site Deposition with Cap/Cover:** This alternative includes the excavation and placement of contaminated soils in discrete locations of the proposed golf course land use area and the capping of them with an engineered cap/cover that would prevent exposure to humans and animals.

- **Off-Site Disposal at Landfill:** This alternative includes the excavation, transport and disposal of contaminated soils in an approved landfill.

- **Wet Screening with On-Site Deposition and Off-Site Disposal of Residuals:** The excavation and wet screening of contaminated soils to separate them into a coarse clean fraction and a fine fraction that can be disposed of at an approved landfill. Soils not requiring disposal would be placed in discrete areas of the proposed golf course and capped with an engineered cap/cover that would prevent exposure to humans and animals.

The detailed analysis was performed to evaluate the No Action and three primary alternatives to ultimately develop preferred alternatives.

ES.10 Preferred Alternatives

During the final evaluation it became apparent that some of the alternatives that were not retained for total Site cleanup were potentially useful in remediating small-scale and Miscellaneous Small RUs. As such, two sets of preferred alternatives were developed; those for large-scale applications and those for small-scale applications and Miscellaneous Small RUs. The selected preferred alternatives defined for cleanup action for each remediation unit are shown below:

Preferred Alternative	Application
Large Scale Applications	
Excavation with On-Site Deposition and Cap/Cover	Golf Course RUs Commercial Land Use RUs
No Action	Open Space RUs
Small Scale Applications	
Cap/Cover	Historical
Excavation with Off-Site Disposal	Miscellaneous Small RUs • Similar mixture of contaminants • Similar deposition method • Small occurrence(s) of a single contaminant • Contamination "hot spots" discovered during final cleanup • Debris
Cap (asphalt)	Miscellaneous Small RUs • Sequalitchew Creek NGRR
Cover	Golf Course Land Use RUs • Fill Areas
No Action	Small occurrences of chemicals that are naturally occurring or where not part of the manufacturing process.

Chapter 1 – INTRODUCTION

1.1 Introduction

This chapter presents the general scope, purpose, and organization of this report.

E.I. duPont de Nemours & Co. (DuPont), the Weyerhaeuser Company (Weyerhaeuser), and the Washington State Department of Ecology (Ecology) have agreed to complete a Remedial Investigation (RI), Health Risk Assessment (RA), and Feasibility Study (FS) for the Former DuPont Works Site (Site) under the terms and conditions defined in Consent Decree No. 91-2-01703-1.

The RI, RA, and FS were conducted according to provisions of the Washington State Model Toxics Control Act (MTCA) as administered by Ecology. Under MTCA, Ecology provides guidance and criteria for the selection of cleanup actions (WAC 173-340-360). MTCA specifies criteria for selecting cleanup actions, which include the permanence of the action, protectiveness, cost, long-term effectiveness, management of short-term risks, implementability and consideration of public concerns. Under MTCA, Ecology also provides general information on the content of a feasibility study (WAC 173-340-350). This FS follows that guidance.

This FS report is a companion document to the RI and RA and should be reviewed in conjunction with these reports.

1.2 Site Description and History

The Site is located in southwestern Pierce County, within the City of Dupont, as shown on Figure 1-1. The former DuPont Works occupied an 841-acre fenced area and included Parcel 1 and Parcel 2 areas, as referenced in the Consent Decree. Remediation of Parcel 2 has been completed and this parcel was released for development by Ecology in December of 1997. This FS only addresses Parcel 1 (i.e., The Site).

The Site is bordered by Weyerhaeuser property to the north and west and WRECO property on the east, and south (Figure 1-1). Burlington Northern railroad property is adjacent to the Weyerhaeuser open space to the west. Puget Sound is located to the west of the Burlington Northern Railroad property.

Activities at the Site during operation of an explosives manufacturing facility resulted in the accumulation of residual chemicals in soils:

- In areas associated with former building foundations;
- In areas where lead paint was used and/or stored;
- In areas where manufacturing materials were stored;
- Along the narrow gauge railroad tracks;
- In waste disposal areas; and
- In low concentrations Site-wide.

1.3 Interim Source Removal

In accordance with MTCA (WAC 173-340-430) and the Consent Decree for the Site (Sections D and E), interim source removal (also referred to as interim cleanup actions) has been conducted to remove soil and/or debris from discrete locations throughout the Site. This work was done between 1990 and 2001. Actions were conducted for five primary reasons:

- To minimize the potential for transport of residual constituents in soil by removing the sources, protect groundwater, and thereby minimize potential future environmental impacts;
- To remove soil and/or debris with high concentrations of constituents to improve the safety and environmental conditions at the Site;
- To remove debris (such as drums and other demolition material overlying fill and native soils) and facilitate a more complete and accurate RI;
- To minimize delays in the Site RI, RA, and FS process; and
- To prepare for the final remediation of the Site.

For each interim source removal (ISR), complete work plans were developed, reviewed by Ecology, and revised in accordance with their comments. Prior to the initiation of any ISR, Ecology's approval to start was obtained. In addition, Ecology was communicated with regularly during these activities either by regular Site visits, periodic telephone call and/or monthly reports.

The ISR was described in a series of Interim Source Removal Memoranda submitted to Ecology following work scope completion. These memoranda referenced in the RI, present the results and provided additional details of each activity.

The total volume of materials removed from the Site during ISR (through December, 2001) included: 60,900 tons of soil; 9,700 tons of debris; 1,540 tons of soil and debris mixtures; 4,836 drums; 69,204 gallons of liquids; and 170 cubic yards (CY) of asbestos-containing material. Materials were recycled off-Site, incinerated off-Site, or sent to an approved landfill.

As a result of these efforts, this is a focused FS, which addresses the residual constituents contained in soil and debris, and the contaminated stockpiled soil generated during ISR.

1.4 RI and RA Summary

The RI investigated four media (i.e., soil, surface water, groundwater, and sediment) and determined that only soil and groundwater were media of concern. The RA evaluated the soil information presented in the RI for compliance against Site-specific cleanup levels (CLs) and remediation levels (RLs). Because chemical constituents in media other than soil and groundwater meet Site-specific CLs and RLs, this FS will focus on these media only. Minor amounts of contaminated debris are also present on-Site and will be addressed in this FS.

The RA identified 25 areas to be addressed in the FS. The basis for determination of any area requiring no further action (NFA) is described in the RA. The RA also identified CLs and RLs associated with future Site land use. Chapter 6 of this FS further evaluates these risks and land uses to assess the value of engineering controls associated with the preferred alternatives to attain the RAOs.

1.4.1 Soil

The sample data collected during the RI indicated that soil on the Site initially contained lead, arsenic, mercury, 2,4-dinitrotolouene and 2,4-dinitrotoluene (DNT), 2,4,6-trinitrotoluene (TNT), total petroleum hydrocarbons (TPH), and carcinogenic polycyclic aromatic hydrocarbons (cPAH) above MTCA screening levels.

Interim Cleanup or Source Removal Actions remediated many of these locations. These interim actions were effective in reducing the potential for impacts to the groundwater by leachable constituents and by excavating, designating, and disposing of soil which would have been difficult to treat on the Site. This FS refers to conditions within each area after completion of these actions.

1.4.2 Debris

Contaminated debris generated during ISR was disposed of off-Site based on characterization sample analytical results. Additional debris remains in-situ and will be addressed in this FS and during final cleanup action.

1.4.3 Groundwater

The RI and RA reported that groundwater impacts (concentrations above drinking water standards) are limited to one contaminant, dinitrotoluene. These concentrations are very close to the drinking water standard and have slowly been slowing decreasing. Groundwater will be discussed further in Chapter 6.

1.5 Future Land Use

The RA and FS assume certain Site land uses. They are divided at Sequalitchew Creek, with industrial uses planned for the area north of the creek and commercial, historical, and recreational (golf course) land uses planned for the areas south of the creek. Open space will occur along Sequalitchew Creek, and will encompass Old Fort Lake and surrounding land. This land use configuration is presented in Figure 1-2. Land use was used as a basis to develop exposure scenarios in the RA to derive preliminary land use and chemical specific CLs and RLs. Further evaluation was done to assess the impacts of engineering controls associated with the alternatives chosen for further evaluation in Chapter 8. In some cases these engineering controls were used to modify the RLs used in the RA and to estimate the impacted soil volumes.

1.6 Identification of Remediation Units

The area of contamination (AOC) policy developed by Ecology (Ecology, 1991) clarifies the definitions of generation and disposal as they apply to waste soil and debris found on MTCA sites. In 1993, Ecology determined that an AOC, which includes all areas within the Consent Decree Boundary (Figure 1-1), would allow on-Site consolidation, handling, and treatment of soil from various Areas on the Site.

Remediation units (RU) are groupings of the Site locations with like land uses. Each RU grouping will be treated with similar technologies and, thus, can be addressed as a single entity for the purposes of the FS. Remediation units were developed to address the residual contamination and associated soil volumes remaining after ISR (as described in Section 1.2). This FS generally uses RUs based on land size and land use type rather than similar chemical types and concentrations, RI Areas, or where deposition of these chemicals is believed to have occurred by similar mechanisms (e.g., application of herbicides). This was done to address the public's concerns over the large variance in size between the RI areas and the lack of total Site coverage. These RUs are shown on Figure 1-2 and described in section 3.2. The exceptions are Miscellaneous Small RUs, which are either small in size or have similar and/or unique characteristics. These RUs are shown on Figure 1-3.

1.7 FS Purpose and Report Organization

The primary focus of this FS is to address soil impacted by lead and arsenic. Soils impacted by other contaminants and contaminated debris occur on Site but comprise relatively small volumes. These

occurrences are referred to as "Miscellaneous Small RUs" throughout this FS. An evaluation of applicable remedial approaches for these RUs is contained in Chapter 7 and in Chapter 8.

The relationship between each section of this FS report and the process used for development and screening of remedial alternatives is presented on Figure 1-4.

This FS report is organized as follows:

- Chapter 2 summarizes RAOs designed to protect human health and the environment. The RAOs take into consideration remediation or cleanup levels identified in the RA and relevant state and federal regulations. The relevant cleanup or remediation levels form the basis of the estimated impacted soil volumes and are also used to assess the feasibility of potential remedial alternatives.

- Chapter 3 defines the RUs and summarizes the impacted soil volumes that will be addressed by the cleanup action.

- Chapter 4 describes applicable technologies and associated process options, and summarizes the screening of those technologies. Preliminary screening was performed based on professional judgment of the effectiveness of the technology and process options to remediate Site soil. Following the preliminary screening to eliminate technologies that are not suitable to remediate constituents at the Site, specific processes were assembled to represent a range of options for each technology. A qualitative screening of process options was then conducted based on effectiveness, implementability, and cost screening criteria. After this screening, at least one specific process was selected to represent each retained technology for combination into plausible remedial alternatives.

- Chapter 5 summarizes the scope, results, and recommendations from the treatability studies performed on various impacted soils.

- Chapter 6 describes and evaluates the application of remedial alternatives (groups of applicable technologies) to the cleanup action at the Site. Initially, groups of applicable technologies were assembled into alternatives that would be plausible for remediation of Site soils. Then, a quantitative screening of each alternative was conducted. The difference between this screening and the initial screening as discussed in Chapter 4 is that the criteria were weighted and the alternatives scored by the FS team (Appendix E), and the individual elements of each criterion were examined in detail.

- Chapter 7 describes the detailed analysis of remedial alternatives. This section includes an analysis and ranking of the remedial alternatives based on the same set of evaluation criteria used in Chapter 6 applied with greater detail. A comparative analysis identifies the performance of the retained remedial alternatives for each criterion. Cost is evaluated in detail using generic unit costs and recent vendor estimates for direct costs. Indirect costs associated with contingency, engineering design, administration, construction oversight, and community relations are also estimated. The recommended alternative for each RU grouping is selected in this section.

- Chapter 8 defines the recommended strategy for the Site cleanup action. The proposed steps for implementation of the selected alternative are described, pairing the selected alternatives with applicable remediation units and land use. Treatment alternatives for Miscellaneous Small RUs, containing other constituents and constituent mixtures, are also detailed.

Throughout this report, tables and figures are presented at the end of each chapter in which they are discussed. These chapters are supplemented by eight appendices, which provide supporting documentation of items discussed in the text.

Chapter 2 – REMEDIAL ACTION OBJECTIVES

2.1 Introduction

The remedial action objectives (RAOs) of future cleanup actions at the Site are to provide remedial alternatives that protect human health and the environment (WAC 173-340-350). The proposed RAOs for the Site are designed to:

- Achieve CLs or RLs that will be protective of human health and the environment; and
- Comply with chemical-, location-, and action-specific applicable, relevant, and appropriate requirements (ARARs).

MTCA (Chapter 173-340 WAC) requires that cleanup actions meet Cleanup Standards at least as stringent as those under the Superfund Amendments and Reauthorization Act of 1986 (SARA), and WAC 173-340-710 requires that all cleanup actions be in compliance with applicable state and federal laws. Section 121 (d) of the SARA requires cleanup actions at Superfund sites to attain the "applicable or relevant and appropriate" requirements of federal and state environmental laws and regulations.

Because of the complexity of the Site, a Site-specific RA using land use specific exposure scenarios was used to develop CLs and RLs protective of human health and the environment (WAC 173-340-700 (3)(c)).

Section 2.2 discusses applicable or relevant and appropriate requirements (ARARs) for the cleanup action(s) at the Site, as specified under MTCA and federal regulations. Section 2.3 presents chemical-specific requirements based on ARARs and risk-based CLs or RLs. Sections 2.4 and 2.5 discuss the location and action-specific ARARs for the Site cleanup action(s). Section 2.6 summarizes the various RAOs identified from a consideration of ARARs and Site-specific risks. These RAOs form the basis for remediation alternatives presented in subsequent sections of this FS report.

2.2 Potentially Applicable State and Federal Requirements for the FS

2.2.1 Introduction

The specific standards that help to determine when RAOs have been met for Site cleanup under a MTCA consent decree are applicable state and federal laws. The selected remedies in the FS must be protective of human health and the environment and comply with these laws.

MTCA (Chapter 90.105D RCW) governs investigation and cleanup of the Site. Cleanup standards in the MTCA regulations (WAC 173-340) consist of the following:

- Cleanup or remediation levels for hazardous substances present at a site (constituent concentrations in affected media).
- Points of compliance (locations where cleanup levels must be met).
- Other regulatory requirements of applicable state and federal laws (requirements that apply to a site because of the type of action and/or the location of the site).

This section of the FS addresses the following: applicable state and federal laws for the cleanup action(s) at the Site, as specified under MTCA; chemical-specific CLs or RLs based on the MTCA regulations and the ARARs; and state and federal laws that apply to cleanup locations and cleanup actions.

2.2.2 Applicable State and Federal Laws

Under MTCA, "applicable state and federal laws" are all legally applicable requirements and those requirements that Ecology determines are relevant and appropriate. Therefore the definition is similar to the federal Superfund concept of "applicable or relevant and appropriate requirements" or ARARs. The term ARARs is used throughout the MTCA regulations and is also used here.

In WAC 173-340-710, MTCA defines legally applicable requirements as those cleanup standards, standards of control, and other environmental protection requirements, criteria, or limitations adopted under state or federal law that specifically address a hazardous substance, cleanup action, location, or other circumstances at a site.

MTCA defines "relevant and appropriate requirements" using the same words as those in Superfund guidance: *"those cleanup standards, standards of control, and other human health and environmental requirements, criteria, or limitations established under state or federal law that, while not applicable to the hazardous substance, cleanup action, location, or other circumstance at a site, address problems or situations sufficiently similar to those encountered at the site that their use is well suited to a particular site"* (italics added). The criteria used to make this determination are presented in WAC 173-340-710(4)(a)-(i).

Remedial actions conducted under a consent decree with Ecology must comply with the substantive requirements of the ARARs but are exempt from their procedural requirements (e.g., obtaining permits and approvals) (WAC 173-340-710(9)). Specifically, this exemption applies to requirements under the Washington State Water Pollution Control Act, Solid Waste Management Act, Hazardous Waste Management Act, Clean Air Act, State Fisheries Code, and Shoreline Management Act. It also applies to local laws requiring permits or approvals.

This section includes a discussion of the three types of ARARs: chemical-, location-, and action-specific. The definitions of these ARAR types and the potential ARARs for the Site that fall into these categories are presented in the following subsections.

2.3 Potential Cleanup Levels and Chemical-Specific ARARs

The remediation of contaminated Site media must meet the cleanup standards developed under MTCA and also meet chemical-specific ARARs. Chemical-specific ARARs include those requirements that regulate the acceptable amount or concentration of a constituent that may be found in or released to the environment.

MTCA requires that CLs or, if allowed, RLs be derived for contaminated media at hazardous waste sites. Ecology allows the use of site-specific data to determine risk-based CLs and RLs. If a calculated CL is less than the natural background concentration or the detection limit, the cleanup level would be set at background or the detection limit, whichever is higher (WAC 173-340-700(4)(d)). The RA used this approach to determine the appropriate CLs or RLs. Institutional controls, as defined by MTCA, can be used in conjunction with remedial actions in developing the cleanup alternatives. Table 2-1 summarizes the CLs and RLs approved for the Site by Ecology. This list was used in the RA to evaluate Site contamination. This list is not inclusive and will require re-evaluation based upon the preferred alternative.

MTCA also requires ecological evaluations at sites that may pose a threat to the terrestrial environment (WAC 173-340-7490 and 173-340-7491). These evaluations may be either simplified (WAC 173-340-7492) or site-specific (WAC 173-340-7493). The RA used Site-specific data to determine ecological soil screening level that is protective of ecological receptors. This screening level was used to screen the evaluation units (EUs).

2.4 Potential Location-Specific Requirements

Location-specific ARARs are those requirements that restrict the concentration of hazardous substances or the performance of activities solely because they occur in specific locations. For each of the following location-specific ARARs, a determination of whether they are applicable or are relevant and appropriate will be made after a detailed development of each FS alternative. A discussion of the location-specific ARARs that potentially apply to the Site follows.

Washington State Shoreline Management Act (Chapter 90.58 RCW; Chapters 173-18, 173-22, and 173-27 WAC): The substantive requirements of this statute and its implementing regulations apply to activities within 200 feet of shorelines in the state, which includes the shoreline of Sequalitchew Creek (WAC 173-18-310) and associated wetlands, but not the shoreline of Old Fort Lake (WAC 173-20-560) or Puget Sound which is over 200 feet from the Site. Proposed remedial actions must be consistent with the policies and goals of the approved Washington State coastal zone management program and with the policies and shorelands use designations of the local jurisdiction's shoreline master plan (Pierce County shoreline designation maps, WAC 173-22-0636).

Pierce County Shoreline Management Use Regulation (Title 20): Shorelines within Pierce County include all marine shorelines, shorelines and associated wetlands of streams with a mean annual flow of at least 20 cubic feet per second (cfs), and lakes and associated wetlands that are at least 20 surface acres (Old Fort Lake is approximately 13 acres). The flow rate of Sequalitchew Creek peaks in the spring and was measured in 1999 at approximately 25 cfs. Pierce County regulation provides constraints on "use activities" such as dredging and shoreline disposal of fill.

Pierce County Development Regulations—Critical Areas (Title 18E): This regulation protects critical areas by limiting any actions that are planned within 150 feet of a wetland or 35 feet of a stream, or near geologic hazard areas (steep slopes) or fish and wildlife habitat areas. Pierce County has mapped in an atlas, critical areas and wetlands in areas it has surveyed. This regulation establishes required buffer zones for actions adjacent to any of the above critical areas. Such actions could include any work along Sequalitchew Creek, and Old Fort Lake.

Washington State Hydraulic Projects Approval (Chapters 75.20.100 Through 75.20.160 RCW; Chapter 220-110 WAC): This statute and its implementing regulations apply to any work conducted in Puget Sound or within the designated shoreline that changes the natural flow or bed of the water body (and therefore has the potential to affect fish habitat). The requirements include bank protection (WAC 220-110-050), saltwater technical provisions, and prohibited work times in saltwater areas, such as juvenile salmon outmigration periods. Any work along Sequalitchew Creek will involve consultation with the Washington State Department of Fish and Wildlife (WDFW) to determine appropriate mitigation measures.

The Fish and Wildlife Coordination Act: The Fish and Wildlife Coordination Act requires actions that will result in the control or structural modification of any natural body of water for any purpose, to protect the fish and wildlife resources that may be affected by the action. The U.S. Fish and Wildlife Service (USFWS) and appropriate state agencies must be consulted to ascertain the means and measures necessary to mitigate, prevent, and compensate for project-related losses and to enhance resources. This regulation applies to any actions taken on Sequalitchew Creek. Fish species using Sequalitchew Creek include chum salmon (O*ncorhyncus keta)*, coho salmon (O*ncorhyncus kisutch*), and cutthroat trout (*Salmo clarki)*. Adult chum are reported to spawn in the lower 650 feet of the creek.

Endangered Species Act (16 USC 1531 et seq.; 50 CFR Parts 17, 225, and 402) : This act protects fish, wildlife, and plants species whose existence is threatened or endangered (T/E). The Coho salmon and the bald eagle are candidate T/E species in the Puget Sound ecologically significant unit. The requirements of this regulatory program apply to cleanup actions that may affect a listed T/E species or designated critical habitat. Applicability will be determined via discussions with the USFWS and the

National Marine Fisheries Service (NMFS), as appropriate. A biological assessment could be required by the agencies to evaluate whether the remedial action is likely to affect endangered species.

Native American Graves Protection and Repatriation Act (25 USC 3001 Through 3013; 43 CFR Part 10) and Washington's Indian Graves and Records Law (Chapter 27.44 RCW): These statutes prohibit the destruction or removal of Native American cultural items (human remains and associated funerary objects, graves, cairns, pictographs, glyptics, or other painted records) and require written notification of their inadvertent discovery to the appropriate agencies and Native American tribe. Because the Site area has been occupied or otherwise used by Native American tribes, remediation activities could uncover Native American graves or other protected items; therefore these programs are applicable to the Site cleanup, but only if the listed items are found. The remedial action must cease in the area of the discovery; a reasonable effort must be made to protect the items discovered before such activity is resumed; and notice must be provided as described above.

Archaeological Resources Protection Act (16 USC 470aa et seq.; 43 CFR Part 7): This program sets forth requirements that are triggered when archaeological resources are discovered. It requires that excavation of these resources be conducted under a permit by professional archaeologists. These requirements apply only if archaeological items are discovered during implementation of the selected remedy.

National Historic Preservation Act (NHPA) (16 USC 470 et seq.; 36 CFR Parts 60, 63, and 800): This regulatory program sets forth a national policy of historic preservation and provides a process that must be followed to ensure that impacts of actions on archaeological, historic, and other cultural resources are considered. NHPA requirements apply to federal sites but should be considered when evaluating location specific ARARs at the Site.

2.5 Potential Action-Specific Requirements

Action-specific ARARs are requirements that define acceptable management practices and are usually specific to certain kinds of activities that occur or technologies that are used during the implementation of cleanup actions.

Washington Dangerous Waste Regulations (Chapter 173-303 WAC): These requirements potentially apply to the identification, generation, accumulation, and transport of hazardous/dangerous (hazardous) wastes at the Site. Under Ecology's Area of Contamination (AOC) policy, if contaminated soil is managed within an AOC, it is not considered to be “generated” as a hazardous waste, even if constituent concentrations would cause it to exceed regulatory levels and ordinarily be called a hazardous waste. Ecology may set an AOC or AOCs for a site-undergoing cleanup under a MTCA Consent Decree. Hazardous waste requirements would therefore not apply unless the wastes resulting from the Site cleanup action were moved outside the boundary of the AOC.

Federal land disposal restrictions (LDRs) under 40 CFR Part 268 require that hazardous wastes be treated prior to being disposed of in a land-based disposal unit. EPA has developed special LDRs for contaminated soil and debris. The treatment standards for these substances are expressed as numerical limits and treatment methods, respectively. These standards would generally not apply to contaminated media disposed of within an AOC; however, they could be relevant and appropriate.

Solid Waste Management Act (Chapter 70.95 RCW; Chapter 173-304 and 173-351 WAC): Potential Site cleanup actions include on-Site treatment and consolidation of solid wastes. MTCA specifically includes the solid waste landfill closure requirements as a potential ARAR. If wastes or contaminated soil are to be disposed of on-site, the design requirements of the solid waste landfill regulations may be relevant and appropriate. These design standards include slope, cover, and other structural requirements.

Water Quality Standards for Surface Waters of the State of Washington (Chapters 90.48 and 90.54 RCW; Chapter 173-201A WAC): This regulation is an action-specific ARAR because the remedial actions at the Site (e.g., soil movement and disposal) must not result in any exceedance of surface water quality standards (unless a short-term modification of water quality has been approved by Ecology ahead of the activity; see WAC 173-201A-110). Surface water quality standards such as turbidity, temperature, and metal limits could apply to the remedial actions.

Ecology has designated Puget Sound as a Class A (excellent) water body; Sequalitchew Creek is also a Class A surface water body. Old Fort Lake would fall into the Lakes class. These classifications determine the beneficial uses that must be maintained for the surface water thus labeled and, therefore, the water quality standards as well (i.e., the higher the water quality, the more stringent the standard may be).

This regulation also governs the discharge of wastewater to surface water and groundwater, including discharges from municipal sewer systems to surface water or groundwater. Finally, it provides for use of best management practices for stormwater management on construction sites. Specifically, Chapter 173-216 WAC requires that all known, available, and reasonable treatment (AKART) be used to remove contaminants from wastewater prior to discharge to meet state surface water and groundwater quality standards.

Federal, State, and Local Air Quality Protection Programs: Regulations promulgated under the federal Clean Air Act (42 USC 7401) and the Washington State Clean Air Act (Chapter 70.94 RCW) governs the release of airborne contaminants from point and non-point sources. Local air pollution control authorities such as the Puget Sound Clean Air Agency (PSCAA) have also set forth regulations for implementing these air quality requirements.

Chapter 173-460 WAC, Controls for New Sources of Toxic Air Pollutants, requires that point-source emissions for major sources of regulated air toxics be treated using best available control technologies for toxics (T-BACT) prior to discharge, and that emissions do not cause ambient air concentrations of these chemical constituents to exceed established ambient source impact levels (ASILs). Chapter 173-460 WAC establishes ASILs for several of the chemical constituents at the Site, including arsenic, mercury, TNT, and PAHs. Similar requirements and ambient concentration limits have been adopted by PSCAA under Regulation III, and it is these local requirements, which are at least as stringent as the state and federal requirements, that apply to the Site.

Department of Transportation Hazardous Materials Regulations (40 CFR Parts 171 Through 180): The U.S. DOT has promulgated regulations that govern the transportation of hazardous materials, including packaging, labeling, placarding, and communications and emergency response requirements. The U.S. DOT and state regulations will apply to any hazardous materials transported off-site as part of the remediation.

Washington State Water Well Construction Act (Chapter 18.104 RCW; Chapter 173-160 WAC): This regulation governs the minimum standards for construction, maintenance, and abandonment of wells, including both water supply wells and resource protection wells (e.g., monitoring wells). These regulations will apply to any Site monitoring wells that are closed (abandoned) as part of the remedial action or new wells installed.

City of DuPont Regulations and Standards: The City of DuPont has established regulations and standards which governs the minimum standards for grading and setbacks from sensitive areas and wetlands. These substantive requirements of these regulations and standards, as they relate to the cleanup process, will be met and addressed as part of the remedial design process.

2.6 Screening of ARARs

A screening of ARARs was conducted to assess their applicability to the Site. Only those that were determined to be applicable were retained as an RAO. The following list identifies the ARARs that are potentially applicable to the Site.

Potential Cleanup Levels and Chemical-Specific ARARs

- The Model Toxics Control Act (Chapter 173-340 WAC).

Potential Location-Specific Requirements

- Washington State Shoreline Management Act (Chapter 90.58 RCW; Chapters 173-18, 173-22, and 173-27 WAC).
- Pierce County Shoreline Management Use Regulation (Title 20).
- Pierce County Development Regulations—Critical Areas (Title 18E).
- Washington State Hydraulic Projects Approval (Chapters 75.20.100 Through 75.20.160 RCW; Chapter 220-110 WAC).
- The Fish and Wildlife Coordination Act.
- Endangered Species Act (16 USC 1531 et seq.; 50 CFR Parts 17, 225, and 402).
- Native American Graves Protection and Repatriation Act (25 USC 3001 Through 3013; 43 CFR Part 10) and Washington's Indian Graves and Records Law (Chapter 27.44 RCW).
- Archaeological Resources Protection Act (16 USC 470aa et seq.; 43 CFR Part 7).

Potential Action-Specific Requirements

- Washington Dangerous Waste Regulations (Chapter 173-303 WAC).
- Solid Waste Management Act (Chapter 70.95 RCW; Chapter 173-304 and 173-351 WAC).
- Water Quality Standards for Surface Waters of the State of Washington (Chapters 90.48 and 90.54 RCW; Chapter 173-201A WAC).
- Federal, State, and Local Air Quality Protection Programs.
- Department of Transportation Hazardous Materials Regulations (40 CFR Parts 171 Through 180).
- Washington State Water Well Construction Act (Chapter 18.104 RCW; Chapter 173-160 WAC).
- City of DuPont Regulations and Standards.

Table 2-1 – Risk-Based Remediation Levels

Constituent	Site Specific Cleanup Levels[1] (mg/kg)	MTCA Method C Industrial Cleanup Level[2] (mg/kg)	Commercial Remediation Level (mg/kg)	Golf Course Land Use Remediation Level (mg/kg)	Historical Remediation Level (mg/kg)	Open Space Remediation Level (mg/kg)
Explosives						
Total DNT	3.0	–	–	–	–	–
2,4,6-Trinitrotoluene	1.75	1,750	1,230	1,230	172	172
Inorganics						
Arsenic	32	90	60	60	32[4]	32[4]
Lead[3]	–	1,000	2,100	2,100	1,500	1,500
Mercury	24	1,050	737	737	247	247
Pesticides						
Aldrin	–	7.7	5	5	0.3	0.3
TPHs and PAHs						
Bunker C	7,600	–	–	–	–	–
Benzo(a)Pyrene	–	18	13	13	0.7	0.7

Notes:
[1]Where remediation levels were calculated for both carcinogenic and noncarcinogenic effects, the value shown in the table is the lower of the two values.
[2]Industrial Cleanup levels were calculated using equations and exposure factors for MTCA Method C (WAC 173-340-745)
[3]Except for the Industrial lead soil level, which is the historical MTCA Method C industrial value, all other lead values were derived by Ecology using the lead biokinetic models for children and adults (Ecology, 1999a).
[4]Value is site-specific background level for arsenic. This level was approved for use by Ecology (Ecology, 1999b).
– = Not developed.

Chapter 3 – ESTIMATED VOLUMES OF SOIL FOR REMEDIATION

3.1 Introduction

This chapter describes the following:

- Site remediation units are defined in Section 3.2;
- Section 3.3 describes the procedures that were used to estimate the impacted soil volumes, and present the volumes of in-place soils by RU type; and
- Section 3.4 summarizes the total estimated soil volume that is addressed in this FS.

3.2 Definition of Remediation Units

RUs are generally defined in this FS as areas of the Site with similar future land uses. The exception is the Miscellaneous Small RUs where the RUs were grouped by distinct constituent types, concentrations, or where deposition of those constituents is believed to have occurred by similar mechanisms. The names and descriptions of the remediation units that are used throughout this FS report are as follows:

Golf Course RUs: All property inside the golf course footprint. There are nine golf course RUs comprising 187 acres. The amount of remediation required in these RUs is related to the alternative selected and ranges from the entire 187 acres to less than 100 acres under a limited cap/cover scenario. Under a limited cap/cover scenario, roughly 73 acres would be used for soil placement and cap/cover.

Open Space RUs: These RUs represent the open space areas of the Site. Four open space RUs occur on-Site. They are North Sequalitchew Creek Canyon, South Sequalitchew Creek Canyon (broken into two RUs) and the Old Fort Lake Greenbelt. These RUs represent 73 acres.

Commercial RUs: All Site property planned for commercial development. There are nine Commercial RUs consisting of approximately 334 acres.

Historical RUs: These RUs make up the areas of the Site that have historic significance. Three historical RUs occur on-Site consisting of approximately 6 acres. They are the Fort Nisqually Cemetery (45PI404), the south Shell Midden (45PI72), and the 1833 Fort Nisqually Site (45PI55. An additional historic site, the small Shell Midden (45PI485) along Sequalitchew Creek, is included in the Sequalitchew Creek open space RU and will be addressed in the same manner as the remainder of that RU.

Miscellaneous Small Remediation Units: These remediation units are those that have unique characteristics and are small in size (less than 2 acres) and volume (requiring excavation of less than 5,000 CY). These unique characteristics could be any of the following:

- Similar mixture of contaminants;
- Similar deposition method (localized spill, localizes disposal site, etc.);
- Small occurrence(s) of a single contaminant;
- Contaminant “hot spots” discovered during final cleanup;
- Debris; and
- Location: An example would be sections of the Narrow Gauge Railroad track within Sequalitchew Creek Canyon. This RU is represented by the linear length of the track and the width of track bed from the toe of the uphill slope and the crest of the downhill slope.

3.3 Soil Volumes

Estimates of soil volume were based on interpretation of sample data collected during the RI and subsequent ISR or characterization efforts. Volumes reported below are pre-remedy estimates. The

actual amount of soil to be excavated during the cleanup action will increase or decrease based on effectiveness of the remedy chosen as verified by the actual field sampling data (i.e., confirmation samples) obtained during the cleanup action, or the error inherent in the volume estimation process.

Only in-situ soils with lead and/or arsenic concentrations above the respective CLs or RLs are included in the estimated soil volumes for remediation. Additional volumes of non-lead and non-arsenic soils are associated with Miscellaneous Small RUs. Estimating the final volume of in-place impacted soil that must be addressed in miscellaneous small units with certainty is very difficult. These units are small and have many unique characteristics. For these units, an alternate approach based on Site knowledge and good technical judgment was developed that will provide reasonable estimates. This approach estimates the total volume associated with contamination discovered as a result of confirmation sampling as 0.5% of the total know volume of arsenic and lead impacted soil. As such, the total volume associated with Miscellaneous Small RUs equals the total known volume plus 0.5% of the total lead and arsenic impacted soil volume Site-wide.

3.4 Soil Volume Estimation Procedures

Soil volumes were estimated using the Pre-RI and RI analytical data and verification sample analytical data from the ISR and maps generated for the RI and RA reports. Excavated volumes are calculated by multiplying the in-place soil volumes by a "fluff" factor, which accounts for volume expansion that results from excavation. Based on laboratory and field measurements of Site soils, an excavation fluff factor of 1.25 was used. These volumes, in some cases, were converted to tons on a 1 CY = 1.4 tons basis. This conversion was developed from actual site data recorded during the 2001 Soil Screening Interim Cleanup Action.

Generally, the excavation depth used to estimate excavated soil volume was 1.25 feet. This estimate is based upon the 95% upper confidence level (UCL) of the actual vertical extent of lead and arsenic contamination statistically above the Site-specific RLs (determined to be 1 foot in depth) and a reasonable safety factor of 25%. The following assumptions/process were used to determine the 95% UCL.

- Each sample point was evaluated to assess the vertical extent of contamination. The depth of each constituent was determined by using the bottom of the sample interval above the RL in a test pit, boring, or hand auger exploration. (No interpolation was used when determining the depth). When surface samples only were above the RL, the depth was set at one foot.
- Once the sample evaluation was complete the sample data was evaluated using Ecology's Threefold Statistical Process to determine at which depth compliance could be reached.

Due to the complexity of the Site and the difficulty in predicting the presence and location of isolated occurrences of lead and arsenic contamination above the Site-specific RLs, four separate methods were used to determine the lateral extent of contamination in each RU.

- For localized contamination, the lateral extent associated with a sample point above the RL was assumed to be 25 feet from the limit of the bermed area or limit of the former building foundation. This estimate was based on best professional judgment of a reasonable scenario for deposition of the constituent, such as construction material (lead sheeting on floors, workbenches). When no depositional constraints were present near the sample location, a 25-foot-square area centered over the sample location approximated the limit of impact. When two or more adjacent samples were above the RL and none of the depositional constraints were present, the area between the sample locations was included.
- The estimate of impacted soil volumes in the Narrow Gauge Railroad Tracks (NGRR) was based on sample analytical results which show that arsenic concentrations decreased significantly beyond 25 feet (see the RI). The length of impacted NGRR was interpolated between sampling locations with concentrations that are above and below the RL.
- For those areas of the Site where concentrations of lead and arsenic contamination approached the RLs, the prediction of the presence or absence of contamination becomes

difficult and impractical. In these areas the entire square footage of the RU was deemed to be contaminated.

- Debris volume was determined assigning an in-situ volume of 740 CY per known location. This estimate assumes a 50-foot by 50-foot lateral occurrence, which is 8 feet deep.

Note that these assumptions were used only for estimating impacted volumes. Actual volumes and limits of excavations will be determined by confirmation sampling conducted during the cleanup action.

3.4.1 In-Place Volumes of Impacted Soil

The following estimates of soil volume were calculated using the assumptions listed. Table 3-1 presents the estimates of in-situ volume of impacted soils by RU. They represent impacted volumes prior to the selection of any remedy. The selection of a remedy will change these volumes either upward or downward.

Golf Course RUs: The estimated in-place contaminated soil volume in the golf course RUs is 301,693 CY. Using the "fluff" conversion factor of 1.25, the excavated volume is 377,117 CY.

Open Space RUs: The estimated in-place contaminated soil volume in these RUs is 117,773 CY. Using the "fluff" conversion factor, the excavated volume is 147,217 CY.

Commercial RUs: The estimated in-place contaminated soil volume in these RUs is 554,987 CY. Using the "fluff" conversion factor, listed above, the excavated volume is 693,733 CY.

Historical RUs: The in-place contaminated soil volume in these RUs is 9,680 CY. Using the conversion factor, listed above, the excavated volume is 12,100 CY.

Miscellaneous Small RUs: The known volumes of the soil requiring remediation, for each Miscellaneous Small RU, are as follows:

- Similar mixture of contaminants: There are 3 locations where this type of occurrence is present. Using the criteria listed above this equates to approximately 173 CY excavated volumes of soil.
- Similar deposition method: There are 9 locations where this type of occurrence is present. Using the criteria listed above this equates to approximately 184 CY excavated volumes of soil.
- Small occurrence(s) of a single contaminant: There are 113 locations where this type of occurrence is present. Using the criteria listed above this equates to approximately 4,689 CY excavated volumes of soil.
- Contamination "hot spots" discovered during final cleanup: Since the impacted soil quantity in "discovered hot spots" is unknown, the impacted soil volume will be estimated at 0.5% of the total lead- and arsenic-impacted soil. As such, the in-situ contaminated soil volume in these RUs is 4,630 CY. Using the "fluff" conversion factor of 1.25, the excavated volume is 5,788 CY.
- Debris: Debris occurs both as stockpiled material and in-situ. Interim source removal/cleanup actions have discovered 20 discrete in-situ debris locations. Their depth and regulatory status is unknown. As such, it was assumed that each of these locations represent 740 CY excavated volume of contaminated debris for a total of 18,500 CY.
- Sequalitchew Creek NGRR: Approximately 2,000 linear feet of NGRR track bed remains in Sequalitchew Creek Canyon that will require remediation. This represents an estimated in-place volume of impacted soil of 1,852 CY. Using the "fluff" conversion factor of 1.25, the excavated volume is 2,315 CY. Estimated Soil Volumes Summary

Table 3-1 presents a summary of estimated in-place soil volumes above RLs for the Site organized by RU. The total excavated volume of soil associated with each remediation unit is also presented in the table. The total estimated volume of excavated soil and debris that may require remediation is approximately 1,261,815 CY. Figure 3-1 identifies the areas where mass excavation will occur.

These estimated soil volumes are to be used as the basis for:

- The screening of technologies and process options (Chapter 4);
- Screening and analysis of alternatives (Chapters 6 and 7);
- Selecting the preferred alternative (Chapter 8); and
- The development of scope for treatability studies (Chapter 5).

Table 3-1 – Estimate of In-Situ Impacted Soil Volume for Each RU

Remediation Unit Type - Mass Excavation	Number of RUs	Acreage	In-situ Volume (CY)	Excavated Volume (CY)	Weight in Tons
Golf Course	8	187	301,693	377,117	527,963
Commercial	11	344	554,987	693,733	971,227
Open Space	3	73	117,773	147,217	206,103
Historic	3	6	9,680	12,100	16,940
Miscellaneous Small RUs	**Occurrences**				
Similar Mixtures	3		139	173	243
Similar Deposition	9		147	184	257
Single Contaminant	113		3,751	4,689	6,564
"Hot Spots"	NA		4,630	5,788	8,103
Sequalitchew Creek NGRR	2,000		1,852	2,315	3,241
TOTAL VOLUME - Soil			994,652	1,243,315	1,740,641
Debris	20		14,800	18,500	25,900
TOTAL VOLUME - Soil and Debris			1,009,452	1,261,815	1,766,541

Notes:
NA = Not applicable.

Chapter 4 – IDENTIFICATION AND SCREENING OF TECHNOLOGIES

4.1 Introduction

This chapter summarizes the development of a list of preliminary screening of technologies and associated process options, and initial qualitative screening of technologies. Section 4.2 presents a list of databases reviewed in developing a list of potentially applicable technologies. Section 4.3 describes the technology screening process. Preliminary screening was performed using engineering judgment to assess the effectiveness of each technology in reducing potential Site risks. Technologies that passed through the preliminary screening were then further qualitatively screened, based on effectiveness, implementability, and cost. Tables 4-1 and 4-2 provide a synopsis of this information. Section 4.4 summarizes representative process options (at least one for each technology) that were selected following qualitative screening for compilation into remedial alternatives as presented in Chapter 6. Appendix A presents a detailed discussion of the general response actions, process options, or technologies, including limitations for cleanup of soils containing certain metals and mixtures of metals.

The screening of technologies and process options in this section focuses on the soil volumes defined in Chapter 3. Additionally, the RAOs summarized in Chapter 2 form the basis for the preliminary screening of technologies and process options.

4.2 Development of Candidate Technologies and Process Options

A list of potentially applicable technologies and process options was developed using the following resources:

- Vendor Information System for Innovative Treatment Technologies (VISITT) database, Version 2.0;
- EPA Risk Reduction Engineering Laboratory (RREL) database;
- EPA Superfund Innovative Technologies Evaluation (SITE) demonstrations;
- Remedial Technologies Screening Matrix and Reference Guide, USEPA and U.S. Air Force, July 1993;
- In-house DuPont Company experience;
- In-house consultant and contractor experience;
- Other consultant reports;
- Treatability studies for other sites; and
- Literature survey.

The technologies are grouped according to "general response actions." These are the broad categories of remedial measures that may be implemented alone or in combination to meet the RAOs. The potentially applicable technologies and process options are presented in the first three columns of Table 4-1. Note that process options are a subset of technologies and describe the different systems, equipment, or chemical processes that were considered as potentially applicable alternatives for remediation of the Site. The fourth column of the table includes a brief description of each process option. This description is included to aid the reader in understanding each process option.

4.3 Technology Screening

Screening of potentially applicable technologies was performed in two steps. First, a preliminary screening was performed to identify technologies that may be applicable to the Site. The preliminary screening was based on a technology's broad-based effectiveness in reducing Site risks. The technologies selected on the basis of preliminary screening then went through a second tier of screening, an initial qualitative screening.

4.3.1 Preliminary Screening

The preliminary screening eliminated technologies or process options, which, for technical reasons, could not be implemented or would not be effective (i.e., technically infeasible), including the following:

- Technologies that have been demonstrated only in a laboratory;
- Technologies that cannot achieve the Cleanup Standards required at the Site; and
- Technologies that are not applicable to the Site for practical reasons.

Table 4-1 summarizes the preliminary screening of technologies and process options. Technologies and process options deemed not applicable are indicated by shading. For example, cryogenic freezing was not a suitable immobilization technology since this process is not a permanent solution. The last column of Table 4-1 presents a brief comment on the applicability of the process option, based on the technology's ability to achieve RAOs. These comments provide explanation as to why a particular process option was retained for further evaluation or rejected.

4.3.2 Technologies That Rely On Stabilization/Solidification

Past interim source/cleanup actions have removed the majority of the known soil locations where lead and arsenic concentrations could potentially be above levels at which characteristic dangerous waste limits could apply. As such, technologies that rely on the mass stabilization of soils to reduce the leachability of lead and arsenic-impacted soils to below the hazardous designation were not retained. Stabilization was retained for further evaluation where the alternative concentrates the contaminants into a smaller volume (i.e. Wet Screening with Stabilization, On-Site Deposition and Cap/Cover).

4.3.3 Initial Qualitative Screening

The process options retained from the preliminary screening were evaluated in the initial qualitative screening. MTCA requires that technologies and processes are screened to determine if the alternatives selected for further evaluation represented those that were permanent to the maximum extent practicable (as defined by WAC 173-340-360 (3)(b)). For this phase of screening the MTCA required criteria were grouped in the following manner:

Effectiveness: Effectiveness contains those criteria that evaluate the state of development of the technology, the ability to protect human health and the environment, and identifies potential negative impacts associated with the technology. Under this heading are the following MTCA criteria:

- Protectiveness: This evaluation considers the degree of protection each technology provides to human health and the environment, the extent to which reductions in risk, toxicity, and/or mobility are expected to be achieved, the time required to reduce risk and obtain cleanup standards, the off-Site and on-Site risks resulting from the implementation of the alternative, and the degree of improvement of the overall environmental quality.
- Permanence: This evaluation considers the degree to which the alternative permanently reduces the toxicity, mobilization or volume of the contaminants. The evaluation considers the materials treated, quantity of material treated, degree of toxicity, mobility, and volume reduction, degree to which the treatment is irreversible, and residuals type and quantity.

- Long Term Effectiveness: This evaluation considers the effectiveness of the process during the time when contaminant concentrations remain on-Site that are greater than CLs or RLs, the magnitude of risk with the alternative in place, and the adequacy and reliability of any Site controls.

- Management of Short Term Risks: This evaluation considers the effectiveness of the process in dealing with the potential impacts to human health and the environment during the implementation phase.

- Consideration of Public Concerns: This evaluation considers any local community concerns over the alternative and how the alternative addresses those concerns.

Implementability: Implementability involves the technical and administrative feasibility of constructing, operating, and maintaining a particular remediation technology. Technical implementability has already been used in the preliminary screening. At this stage, the emphasis is placed on the institutional aspects of implementability, such as the ability to obtain the necessary permits; the availability of treatment, storage, and disposal services; and the availability of necessary equipment and skilled workers to implement the technology.

Cost: The cost for remediation work includes such items as installation and operation of process equipment, excavation, and disposal fees. The cost analysis is made on the basis of engineering judgment, and each process is evaluated as to whether costs are high, medium, or low relative to other process options in the same technology category.

Table 4-2 summarizes the evaluation of the general response actions, technologies, and process options retained after the preliminary screening. In Table 4-2, process options that do not meet the screening criteria and were not considered acceptable based on this initial qualitative screening are indicated by shading. The remaining process options and technologies were retained for further development, assembly, and analysis as remedial alternatives in Chapter 6.

4.4 Representative Processes Selected for the Development of Alternatives

The technologies selected from the two-step screening process include several process options. The "cover" technology, for example, includes eight process options (clean soil cover, re-vegetation, synthetic membrane cap, clay cap, asphalt cap, asphalt/concrete cap, cement cap, and multimedia cap). Many of these process options are similar since they reduce potential exposure. To include all combinations of process options in the development of alternatives would result in the evaluation of hundreds of alternatives with limited benefit.

In some cases, the various process options are sufficiently different in their performance that one would not adequately represent the other. In these cases, more than one process option may be selected for a technology type. For example, under the volume reduction technology it was concluded that classification and screening were sufficiently different in performance and cost for both to be included in the remedial alternative development.

The following soil process options were selected as representative:

Technology	**Representative Process Option(s)**
Access Restrictions	• Deed Restrictions
Monitoring	• Soil Sampling
Cover	• Soil Cover
Cap	• Synthetic Membrane • Asphalt/Concrete Cap • Portland Cement Cap • Multimedia Cap
Cap/Cover	• Multimedia Cap • Soil and Gravel Cap
Dust Control	• Water Spraying • Plastic Cover
Immobilization	• None Selected
Excavation	• Conventional Equipment
Off-Site Disposal	• Hazardous Waste Landfill • Demolition Debris Landfill
Recycling	• None Selected
Thermal	• None Selected
Volume Reduction	• Solvent/Chelant Extraction • Acid or Base Extraction • Soil Classification • Sieving and Screening

These technologies and representative process options are discussed in greater detail in Appendix A. The actual process options to be used will be defined in the Cleanup Action Plan. The technologies and representative process options identified in this section are combined into alternatives in Chapter 6 and evaluated in more detail in the remainder of this FS.

Table 4-1: Preliminary Screening of Technologies and Process Options

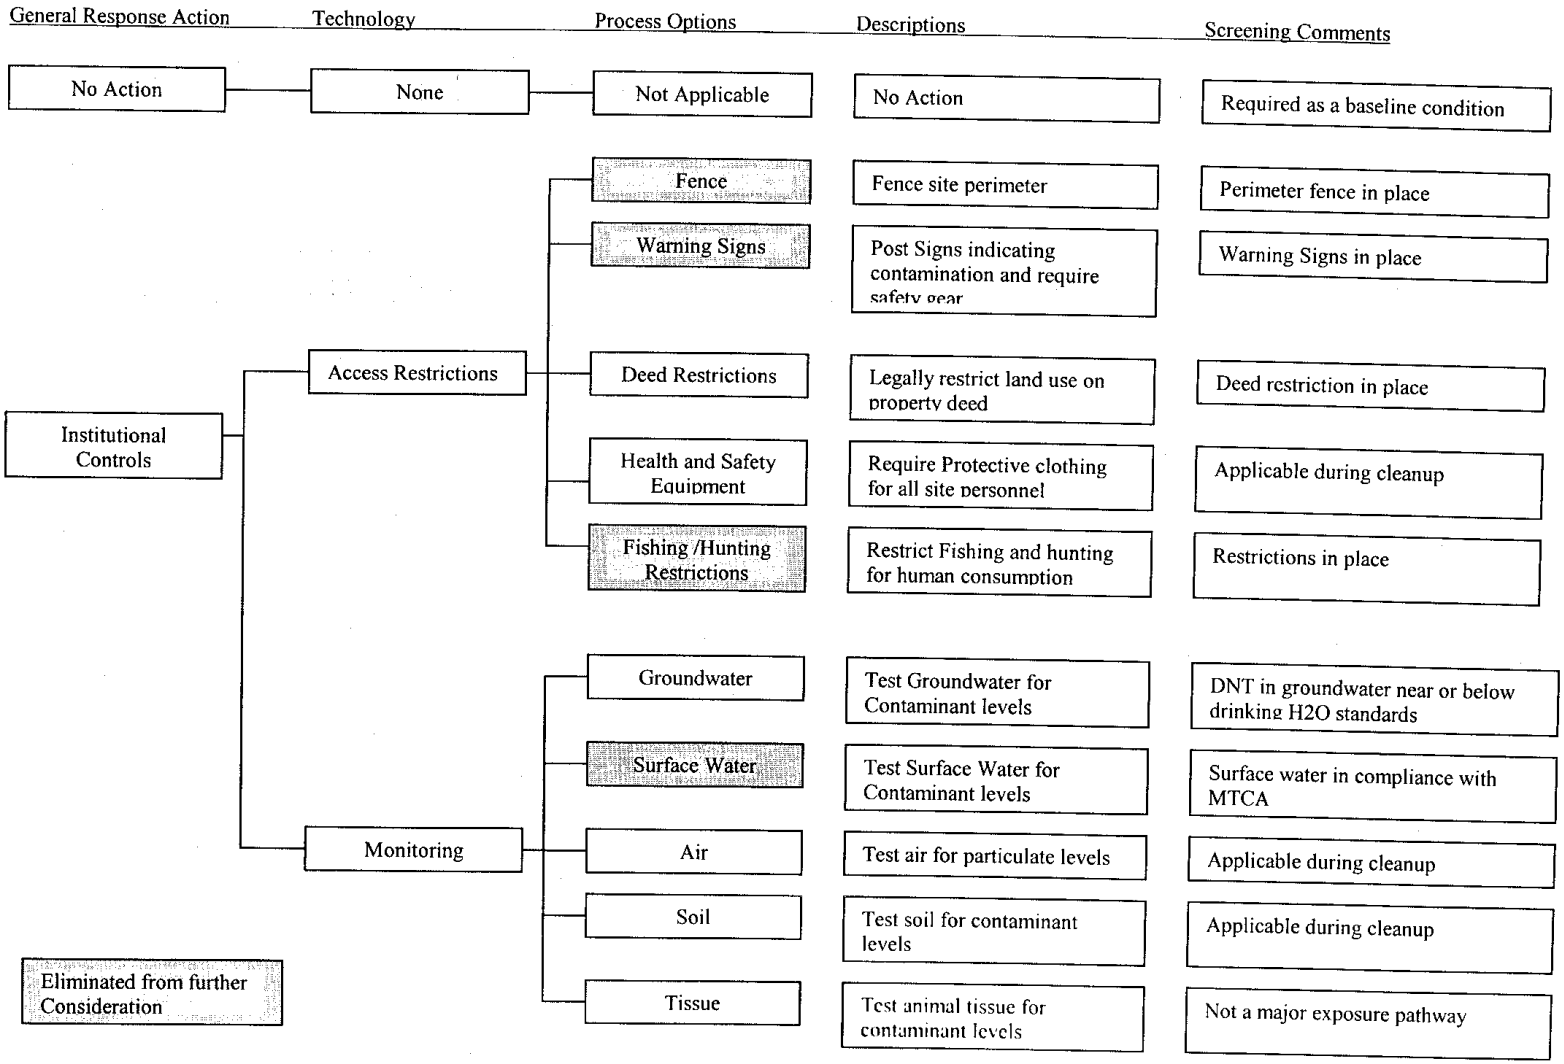

Table 4-1: Preliminary Screening of Technologies and Process Options

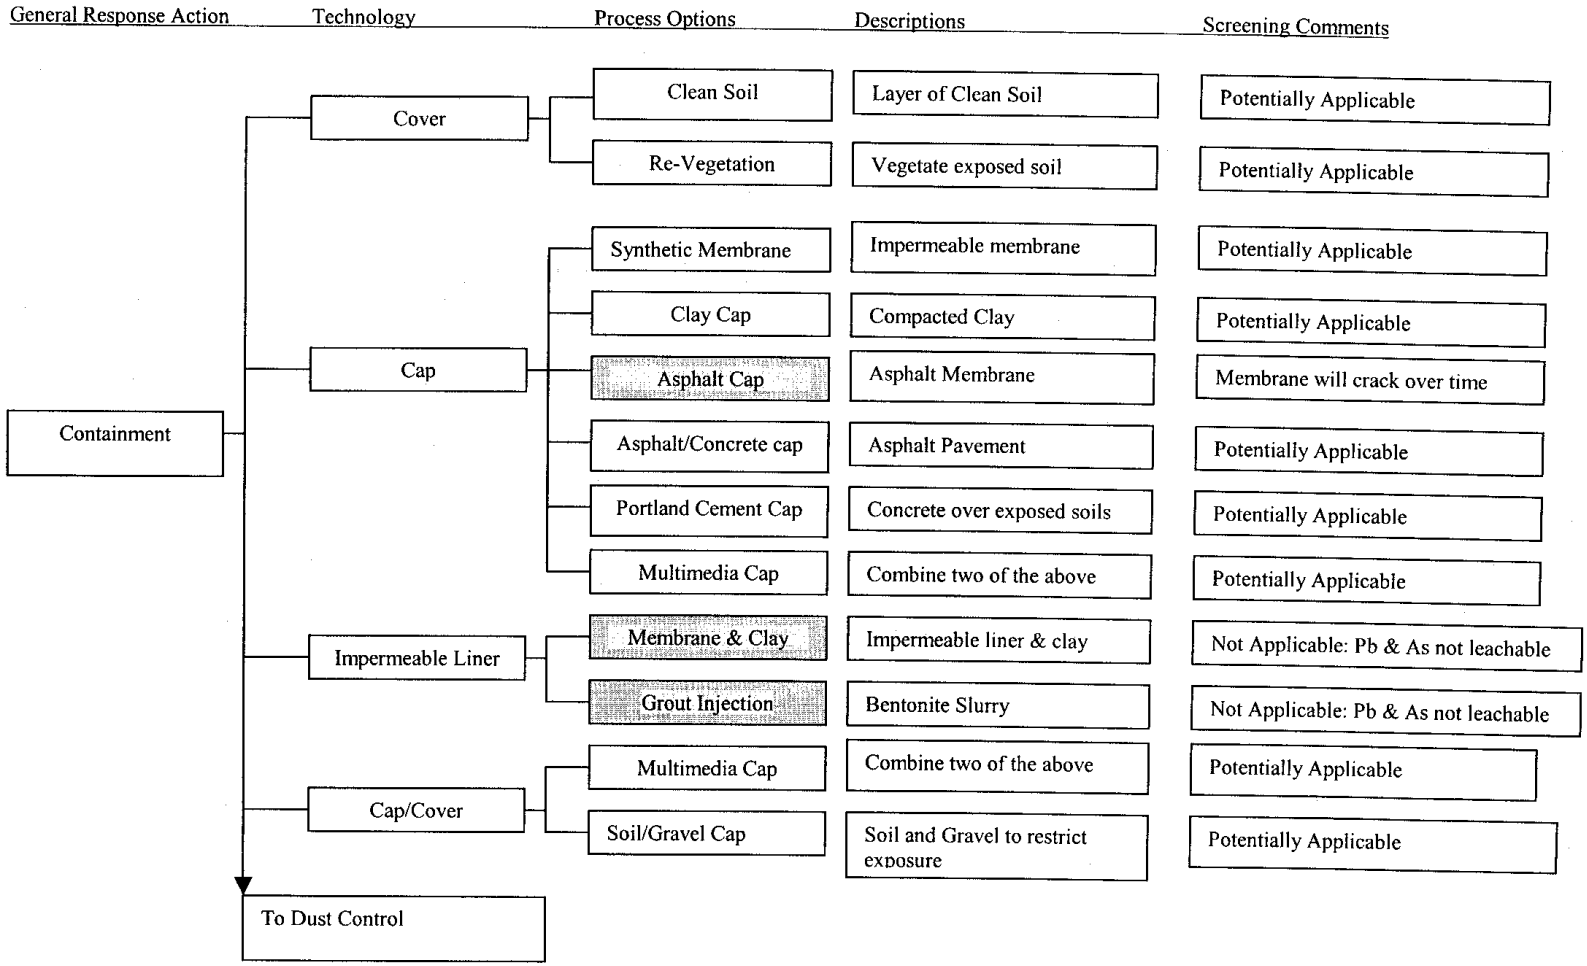

Table 4-1: Preliminary Screening of Technologies and Process Options

General Response Action	Technology	Process Options	Descriptions	Screening Comments
Containment	Dust Control	Water Spraying	Wet Exposed Soils to prevent dust	Potentially Applicable
		Dust Suppressants	Apply chemical binder to exposed Soils to prevent dust	Potentially Applicable
		Wind Fence	Barrier to deflect wind	Irregular wind direction
		Plastic Cover	Plastic cover over exposed soils	Potentially Applicable
		Vegetation	Temporary vegetation cover over exposed soils	Timeframe for growth inhibits production

Eliminated from further Consideration

Table 4-1: Preliminary Screening of Technologies and Process Options

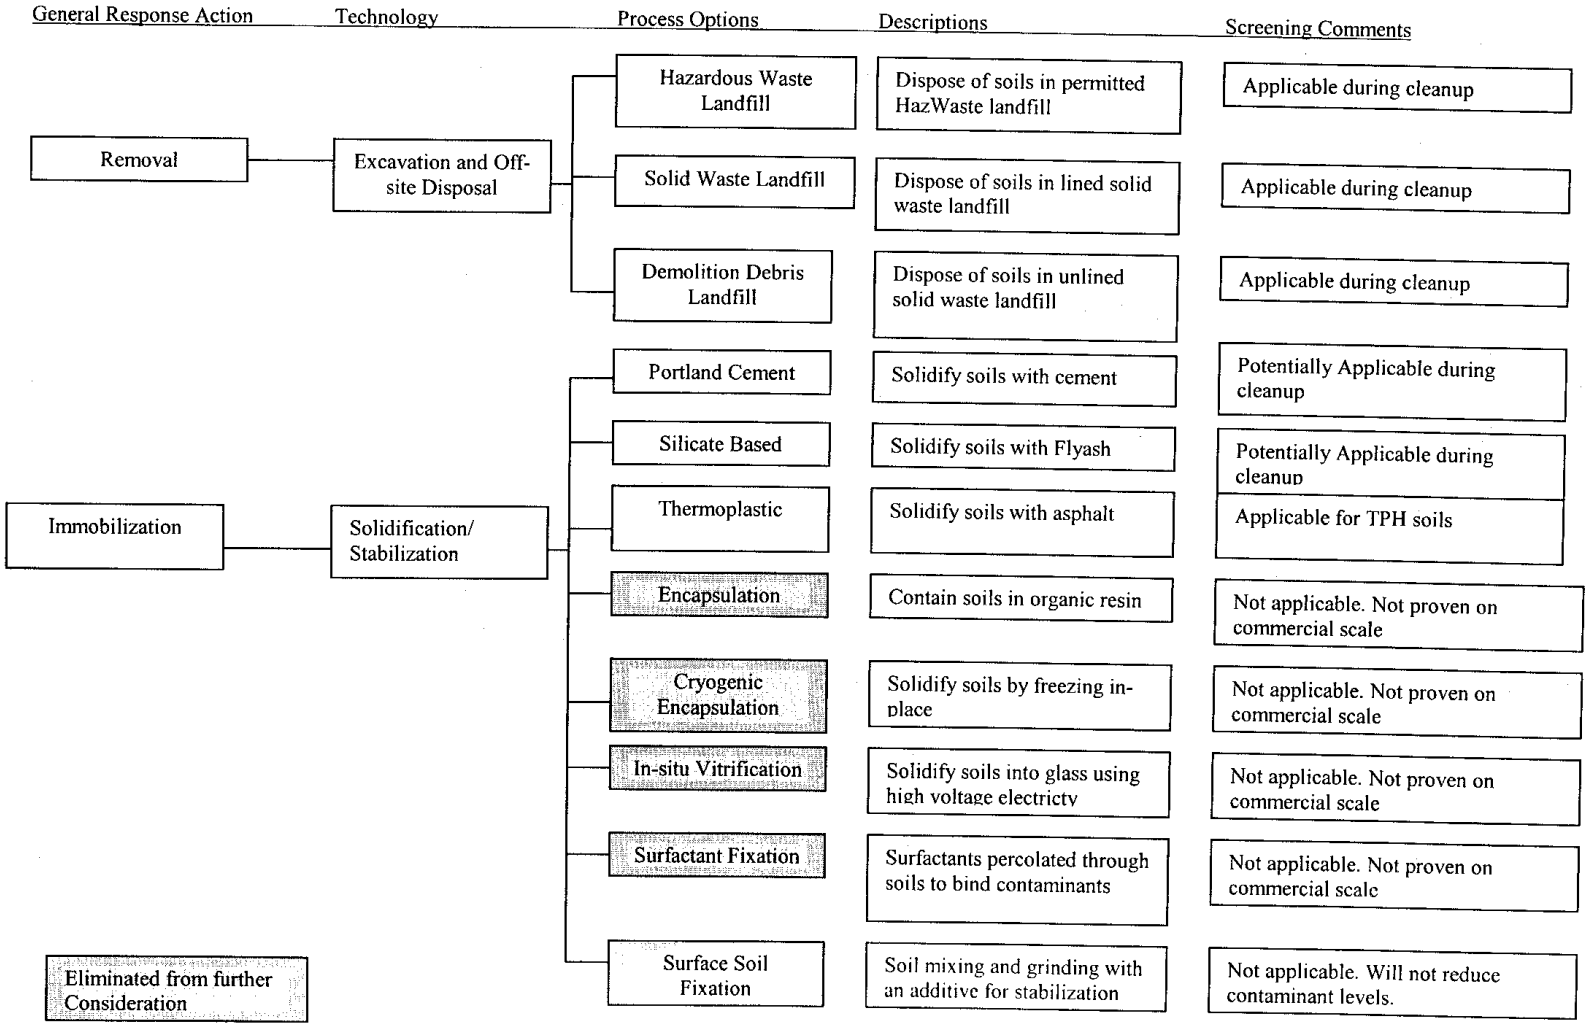

Table 4-1: Preliminary Screening of Technologies and Process Options

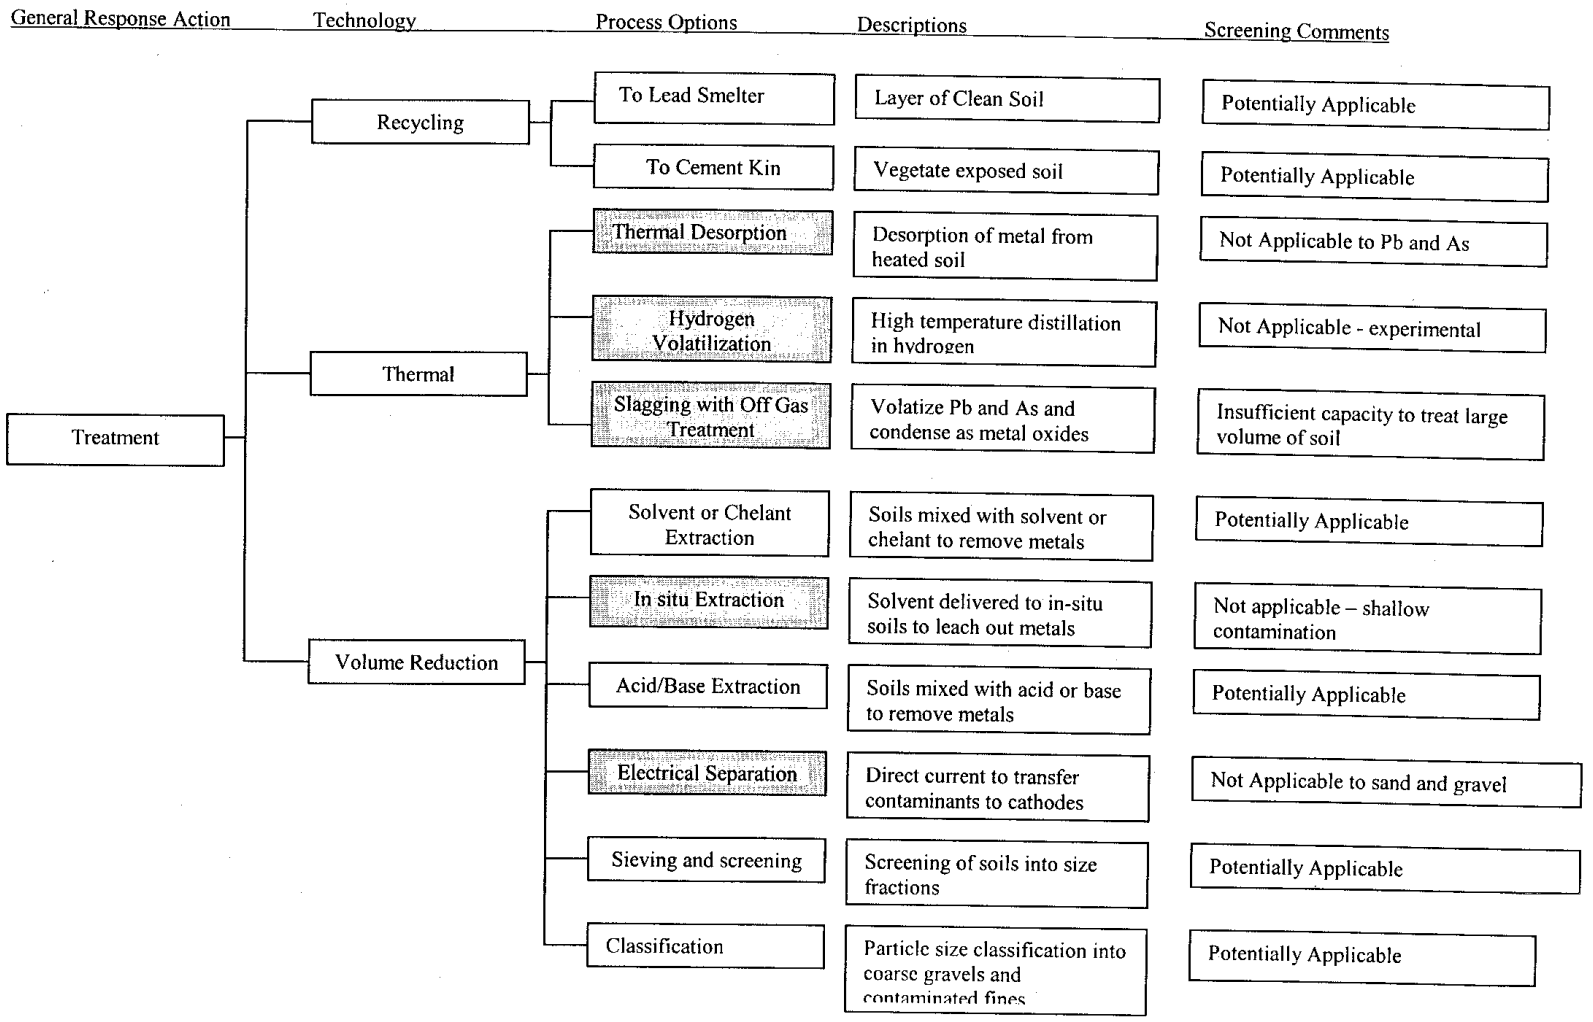

Table 4-2: Evaluation of Process Options

General Response Action	Technology	Process Option	Effectiveness	Implementability	Cost
No Action	None	None	Not Effective, Unacceptable to Companies and Ecology	Easily Implemented	Very low
Institutional Controls	Access Restrictions	Deed Restrictions	Some effect in reducing exposure, does not reduce contamination	Easily Implemented	Low
		Health and Safety	Some effect in reducing exposure, does not reduce contamination	Easily Implemented	Low
	Monitoring	Groundwater	Useful for documenting conditions, does not reduce contamination	Easily Implemented	Low
		Air	Useful for documenting conditions, does not reduce contamination	Easily Implemented	Low
		Soil	Useful for documenting conditions, does not reduce contamination	Easily Implemented	Low
Containment	Cover	Clean Soil	Moderately effective in reducing exposure	Easily Implemented	Low
		Re-vegetation	Marginal effect in reducing exposure	Easily Implemented	Low
	Cap	Synthetic Membrane	Effective in reducing exposure	Easily Implemented	Moderate
		Clay Cap	Tends to crack over time	Clay not readily available	Moderate
		Asphalt/Concrete Cap	Effective in reducing exposure	Easily Implemented	Moderate
		Portland Cement Cap	Effective in reducing exposure	Easily Implemented	Moderate
		Multimedia Cap	Effective in reducing exposure	Easily Implemented	Moderate
	Cap/Cover	Multimedia Cap	Effective in reducing exposure	Easily Implemented	Moderate
		Soil/Gravel Cap	Effective in reducing exposure	Easily Implemented	Moderate
	Dust Control	Water Spraying	Effective in reducing dust during remediation	Conventional construction practice	Low
		Dust Suppressants	Effective in reducing dust during remediation	Conventional construction practice	Moderate
		Plastic Cover	Effective in reducing dust from stockpiles	Conventional construction practice	Low

Eliminated from further consideration

Table 4-2: Evaluation of Process Options

General Response Action	Technology	Process Option	Effectiveness	Implementability	Cost
Removal	Excavation and Off Site Disposal	To Hazardous Waste Landfill	Effective in eliminating contamination on site, does not reduce contamination.	Moderately easy to implement	High
		To Solid Waste Landfill	Not effective for contaminated soils	Easily implemented	Moderate
		To Demolition Debris Landfill	Not effective for contaminated debris Effective for clean debris	Easily implemented	Low
Immobilization	Solidification/Stabilization	Portland Cement	Effective for wide range of chemicals, does not reduce total concentration of contaminates in soils	Easily implemented	Moderate
		Silicate- Based	Effective for wide range of chemicals, does not reduce total concentration of contaminates in soils	Easily implemented	Moderate
		Thermoplastic	Effective for wide range of chemicals, does not reduce total concentration of contaminates in soils	Easily implemented	High
Treatment	Recycling	Recycle to Lead Smelter	Effective for Lead	Difficult to implement due to availability of smelters	High
		Recycle to Cement Kiln	Effective for chemical which pass TCLP	Difficult to implement due to availability of Kilns	Low
	Volume Reduction	Solvent/Chelant Extraction	Effective in reducing volume of contaminated soil	Easily implemented	High
		Acid/Base Extraction	Effective in reducing volume of contaminated soil	Easily implemented	High
		Sieving and Screening	Effective in reducing volume of contaminated soil	Easily implemented	Low to Moderate
		Classification	Effective in reducing volume of contaminated soil	Easily implemented	Moderate

Eliminated from further consideration

Chapter 5 – TREATABILITY STUDIES

5.1 Introduction

This chapter describes treatability studies that were conducted to further evaluate the technical and economic feasibility of applying the selected technologies to Site soils impacted by lead and arsenic.

Section 5.2 describes the objectives of the treatability studies; Section 5.3 describes the approach taken and summarizes the treatability studies conducted; Section 5.4 summarizes the pertinent results and provides an interpretation to be used in the selection of alternatives (Chapter 6) and their subsequent detailed analysis (Chapter 7). Section 5.5 summarizes the conclusions of the treatability studies and provides recommendations for additional treatability work.

5.2 Treatability Study Objectives

Extensive treatability studies were mainly completed prior to 2000/2001. They were mainly used to help understand lead/arsenic distribution and interactions with Site soils. The studies were also used to investigate ways to address high concentrations of lead- and arsenic-impacted soil. The 2000/2001 ISR actions removed the high concentrations of lead and arsenic soil (above "dangerous waste limits").

Only small amounts of high concentrations of lead and arsenic soil now remain, after 2000/2001, and these soils are in the miscellaneous small RUs. Though the pre-2000/2001 treatability studies will not play a major role in selecting/evaluating preferred alternatives for final cleanup, since they were geared to high concentrations of soils, they are still presented in this Chapter. The treatability studies still provide background, understanding and insight into how remaining lead- and arsenic-impacted soils can be managed to meet RAOs.

Various treatability studies were conducted to aid in the evaluation of treatment technologies related to physical screening and/or soil washing with extraction. This group of technologies was identified in Chapter 4 as a key component in developing remedial alternatives (Chapter 6) and their subsequent detailed analysis (Chapter 7). These studies where also useful in the design and completion of the 2001 Wet Screening ISR Program. The focus of these studies was to obtain data to:

- Confirm the suitability of these technologies for Site-specific soils;
- Identify potential problems associated with these technologies for application at the Site; and
- Define additional treatability work that may be conducted prior to Site remediation.

Lead- and arsenic-impacted soil remediation technologies that take advantage of the concentration distribution of constituents between the different size fractions of the soil matrix were the primary technologies investigated. Typically, higher concentrations of metals are associated with the smaller grain size soil fractions. By physically segregating the soils into two or more fractions, the following would be obtained:

- A coarse fraction that contains metal concentrations below remediation or cleanup levels that can be returned to the Site as soil for backfill; and
- One or more fine fractions that contain metal concentrations above remediation or cleanup levels that will require further treatment.

Wet Screening and Classification processes were investigated for their ability to achieve physical segregation. Soil Washing with Extraction was examined for constituent extraction potential. Recycling to a Thermal Process was investigated to assess the potential for treating the finer separated soil fractions that would be expected to exceed the remediation or cleanup levels.

The principal objectives of the treatability studies were to:

- Determine the grain size distribution of soil present at the Site;
- Determine the constituent distribution by soil grain size;
- Determine the chemical nature of the constituent; and
- Evaluate volume reduction potential by removal of "clean" soil fractions.

Table 5-1 summarizes the relevant soil characterization parameters used to assess the viability of the above-referenced treatment technologies.

5.3 Treatability Study Approach

The treatability study program used comprehensive soil characterization and speciation studies and bench-scale treatability testing to obtain data on the fundamental physical and chemical properties of the impacted soils. An overview of the program and the pertinent results are summarized in Appendices C and D.

The soil characterization parameters, a description of how the parameters are used, and the specific test types are presented in Table 5-2. (More detailed definitions of the parameters and the testing procedures are summarized in Appendix B.) The soil characterization parameters are organized in Table 5-2 as follows:

Physical Properties that may impact materials handling (e.g., during excavation, stockpiling, treatment, and residuals management). These include particle size distribution and Atterberg limits (liquid limit, plastic limit, and plasticity index) that are used to determine the USDA soil classification. Other physical properties measured were moisture content and bulk density of both loose and packed soil.

Regulatory Analyses to determine regulatory classification of waste streams which provides information for management and disposal of treatment residuals in accordance with federal, state, and local regulations.

Chemical Analyses to gather information on soil chemistry, soil mineralogy, soil/constituent interactions, and the distribution, speciation, and mobility of the lead and arsenic constituents. The chemical analyses and the information they provide include the following:

- pH and Generalized Acid Neutralization Capacity (GANC) measure the alkalinity or acidity of the soil and indicate inherent buffering capacity;
- GANC and Reverse GANC (RGANC) are soil leaching tests that measure a soil's capacity to buffer an acid or a base. This information can be used to design solidification/stabilization design mixes. It can also be an aid in designing acid or base extraction treatment processes;
- Organic carbon and anions analyses indicate the potential to provide bonding sites for heavy metals;
- Soluble cations analysis indicates the potential for competition with the heavy metals for bonding sites; and
- Scanning Electron Microscopy (SEM) and sequential extractions determine the specific chemical form of the metal in the soil matrix and the bonding mechanism. This information may be used when chemical reactions such as metals dissolution (in soil washing processes) and metals precipitation (removal of metals from solvent used in a soil washing process) are included in soil treatment.

Because of constituent concentrations for soil samples vary both vertically and horizontally, samples were analyzed for total constituents prior to conducting treatability testing. Thus, treatability study sample results were representative of the bulk of the Site soils likely to require cleanup action.

Table 5-3 lists the treatability studies conducted in support of lead and arsenic remediation at the Site. A detailed soil characterization program conducted by Hazen Research Inc. (Hazen), at its facility in Golden, Colorado, represents the majority of the treatability study work. Constituent speciation work, physical screening studies, and bench-scale technology evaluations were performed by Battelle Pacific Northwest Laboratories, Hart Crowser, State University of New York, and Weyerhaeuser Analytical and Testing Services.

The following sections briefly describe each treatability study and summarize the results. In addition, the results are evaluated in terms of the physical parameters (soils handling properties), technical feasibility of the remediation alternatives, and chemical parameters.

5.3.1 Lead- and Arsenic-Impacted Soils Characterization Study - Hazen Research Inc.

This study involved soil samples collected from Site areas impacted by lead and arsenic, and included detailed characterization and speciation analysis of the lead- and arsenic-impacted soils. Soil sampling for the characterization study used a statistical procedure based on EPA SW-846 guidance, recognized technical literature on sampling and analysis, and the experience of the Project Team. The sampling procedure enabled recovery of representative composite samples of impacted soils from randomly sampled grids in areas of the Site known to contain elevated concentrations of lead and arsenic.

Complete results for the lead and arsenic characterization are detailed in the final reports prepared by Hazen Research (1993a through 1993f and 1994a through 1994c). Six composite samples of lead-impacted soil and three composite samples of arsenic-impacted soil were collected from different Areas of the Site. The characterization results are summarized in Tables 5-4 and 5-5 for lead and arsenic, respectively. A full description of the Hazen Research soil characterization studies for lead and arsenic, and a discussion of the results obtained, is provided in Appendix C.

5.3.2 Arsenic Wet Screening Study - Hart Crowser, Inc.

Arsenic treatability studies were performed by Hart Crowser to better define the distribution of arsenic concentration with respect to soil particle size through the use of particle size distribution testing and associated arsenic analysis of sized soil fractions. Samples were collected in the Reference Grid Area, and the NGRR area to supplement the results of the Hazen arsenic characterization study completed on samples from Areas 18 and 36 and the NGRR. A summary of the results is provided in Table 5-6 and further details of the treatability study procedures and results are presented in Appendix D.

5.3.3 Arsenic Speciation Analysis - Battelle Pacific Northwest Laboratory (PNL)

Battelle PNL performed limited arsenic speciation analysis on soil samples collected from Areas 5, 25, and 38, and in the NGRR area. The purpose of this study was to identify ionic species of arsenic and investigate the presence of arsenic forms in Site soils potentially impacted by acid production (Areas 5 and 25), the use of arsenic-based herbicides (NGRR), or arsenic-based paint/ink (Area 38). The results are summarized in Table 5-7.

5.3.4 Bench-Scale Soil Leaching Study – State University of New York, Buffalo

A screening of non-proprietary soil leaching chemistries was performed by the Department of Civil Engineering at the State University of New York at Buffalo (UB) (State University of New York at Buffalo, 1994). The efficacy of various soil washing extraction agents and leaching conditions were evaluated for removing lead from a lead-impacted soil sample (-8 to +200 mesh fractions) from Area 40 of the Site. The results of this study are summarized in Table 5-8.

5.3.5 Bench-Scale Soil Leaching Study - Weyerhaeuser Analytical and Testing Services

To investigate the potential for using non-proprietary leaching chemistries to remove arsenic from the Site soils, a leaching study was carried out at the laboratories of Weyerhaeuser Analytical and Testing Services (Weyerhaeuser ATS). Several leaching solutions were applied to -1/4 inch by +200 mesh fractions of combined soil samples from Area 18 and the NGRR area. The effects of pH and liquid:solid ratio were investigated as well as performance under single-stage batch and multistage countercurrent extraction regimes. The results of the study are presented in Appendix C.

5.4 Interpretation of Results

In this section, the results of the treatability studies are discussed by treatment technology using the parameters relevant to each technology as presented in Table 5-1. For each parameter, the results that are applicable to handling and remediation of Site soils are discussed.

5.4.1 Physical Screening/Soil Washing

The relevant characterization test results for physical screening/soil washing with dissolution technologies (as shown in Table 5-1) are silt/clay content, constituent distribution with regard to particle size, surface area calculations, Atterberg Limits, organic carbon, GANC/RGANC, MANC/RMANC, and Sequential Extraction for speciation analysis.

The silt/clay (less than 200 mesh particle sizes) content of the Site soils ranged between 6% and 15 % for the samples tested, well below the 40% upper limit generally considered likely to limit the effectiveness of soil washing processes. The sand (greater than 200 mesh and smaller than 1/4 inch particle sizes) content of the Site soils varies between 26% and 53% and the gravel (greater than 1/4 inch particle sizes) content varies between 38% and 66% by weight.

The lead content in the silt/clay fraction of the Site soils is substantial at between 27% and 67% of total lead in soil, which suggests that significant volume reduction of lead-impacted soil could be achieved by separating the fine material from the whole soil. Classification to separate soil at the 100 mesh cut point would represent recovery of about 90% of whole soil mass suitable for on-Site deposition in appropriate land use areas.

Wet screen particle size distribution test results and corresponding chemical analyses results for separated size fractions indicate that between 84% and 97% of the soil lead is concentrated in the sand and silt/clay fractions. These fractions represent between 40% and 62% by weight of the whole soil. These results indicate that recovery of the cobbles and gravel fraction (representing between 38% and 60% of the whole soil) as "clean" material could be readily achieved using conventional wet screening or soil washing to achieve segregation of Site soils into different size fractions.

The arsenic content in the silt/clay fraction of the soils is between 51% and 71% of total arsenic in soil (corresponding concentrations range between 186 and 2,550 mg/kg), which suggests that significant volume reduction of arsenic-impacted soil could be achieved by separating the fine material from the whole soil. Classification to separate soil at the 100 mesh cut point would represent recovery of about 90% of whole soil mass suitable for on-Site deposition in appropriate land use areas.

Particle size distribution test results for Site soils and corresponding chemical analyses results for separated size fractions indicate that between approximately 79% and 92% of the soil arsenic is concentrated in the sand and silt/clay fractions. These fractions represent between 27% and 56% of the whole soil. These results indicate that recovery of the cobbles and gravels fraction (representing between 44% and 73% of the whole soil) as "clean" material could be readily achieved using conventional wet screening or soil washing to achieve segregation of Site soils into different size fractions.

For water-based soil washing processes, the wet screening and Sequential Extraction test results indicate that, because of the low aqueous solubility of lead or arsenic from Site soils, little or no water treatment provisions would be necessary.

The surface area calculations for each of the soil size fractions indicate, as expected, that the majority of the total soil surface area is contained in the silt and clay (64% to 83%), with less in the sands (17% to 36%), and least in the cobbles and gravel (<1% to 2%).

In the case of Areas 7 and 18, the lead distribution by size fraction increases with reducing size fraction and increasing surface area; these results indicate that lead bonding and binding is mostly surface-related. The lead distribution for Areas 36 and 40 in the sand and silt/clay fractions does not proportionally follow surface area distribution; this indicates that lead is not only surface bound but is also associated with other particulate matter present in the soil matrix. In the case of Area 36 soils, SEM confirmed the presence of particulate lead. The presence of metallic lead suggests that density separation techniques may need to be incorporated into the design of a soil washing system.

The arsenic distribution by size fraction for the Area 36 sample increases with reducing size fraction and increasing surface area; these results indicate that arsenic bonding and binding is mostly surface-related.

The very low silt/clay content and results of the Atterberg Limits testing show that the Site soils are non-plastic and should be both amenable to processing by physical screening equipment and easy to handle with conventional earth-moving equipment.

The organic carbon content of the Site soils (0.6% to 6.9%) is below the 10% upper limit generally considered to reduce removal efficiency in a soil washing system because of contaminant-carbon bonding. The inclusion of an organic carbon removal unit operation should not be necessary.

The GANC/RGANC results show that the Site soils have little buffering capacity and will not require the addition of large amounts of acid (to mobilize lead species) or base (to mobilize arsenic species) in a chemically enhanced soil washing system to achieve the desired pH change.

The ELP results (0.02 to 0.06 mg/L) demonstrate very low lead solubility with synthetic acid rain. The wet screening and Sequential Extraction test results also demonstrate that the lead species are relatively insoluble in water. The lead was more soluble in acetic acid solutions, as demonstrated by TCLP, GANC, and Sequential Extraction test data. These results indicate that lead is essentially immobile under normal environmental conditions, but can be mobilized under more rigorous leaching conditions.

The MANC/RMANC equilibrium lead concentrations in the aqueous phase occur between additions of 2 to 40 equivalents of acid/kg soil and between additions of 2 to 40 equivalents of base/kg. One stage acidic and alkaline leaching at 20:1 liquids:solids ratio can remove 45% to 75% of the lead using 2N acetic acid, or 13% to 40% lead using 2N sodium hydroxide. This indicates that acidic leaching has potential for use in conjunction with wet screening and other physical (gravity, density, and high-energy attrition) treatment techniques. Even under severe leaching, a maximum of 75% lead removal is achieved because of the presence of some extremely leach-resistant forms of lead.

In the consideration of MANC/RMANC equilibrium arsenic concentrations, high acetic acid concentrations (approximately 14 equivalents of acid/kg soil) were required to leach arsenic, whereas RGANC indicated that about two base equivalents/kg soil were required for optimum leaching. One stage acidic/alkaline leaching at 20:1 liquids:solids ratio can remove 2% to 4% of the arsenic using 2N acetic acid, but amounts of between 74% and 80% can be removed using 2N sodium hydroxide. These results indicate that chemical leaching using alkaline reagents has potential for use in conjunction with wet screening and other physical treatment techniques. Conversely, mildly acidic conditions might be employed in a soil washing with dissolution treatment scenario to ensure that arsenic remains concentrated in the fines fraction, which could subsequently be stabilized.

In the sized fractions examined, Sequential Extraction data show that lead is predominantly present as carbonate, specifically adsorbed and ion-exchangeable forms, as well as being associated with iron and manganese oxides and organic material. This speciation information also indicates that further lead removal could be achieved in a chemically enhanced (acidic) soil washing or leaching treatment system.

Sequential Extraction data show that arsenic is predominantly present, in the sized fractions examined, in association with iron and manganese oxides and organic material. Speciation analyses performed on selected sized fractions (gravity separated as appropriate) using SEM confirmed the Sequential Extraction test results. The Battelle PNL speciation analysis also indicates that, in the areas of the Site sampled (Areas 5, 25, 38, and NGRR), arsenic is largely present as As(5). This speciation information supports the conclusion that chemically enhanced (basic) soil washing or leaching treatment could be used to liberate arsenic from the soils.

The results of the UB soil washing with dissolution study provide further support for considering a chemically enhanced treatment application. The study shows that strong mineral acid extractants (specifically, hydrochloric and perchloric acid) at approximately pH 1 were effective at significantly reducing (by greater than 60%) lead concentrations by approximately 1,400 mg/kg in the sand fraction of Site soils. TCLP lead values for treated samples ranged from 0.3 to 0.5 mg/L. Less acidic conditions (pH 3) were also effective if a chelating agent (such as EDTA) was added.

The results of the Weyerhaeuser ATS leaching study confirm the leaching data generated under the Hazen study and further demonstrate that sodium hydroxide caustic solutions are effective in removing arsenic from the Site soils. In single-stage batch extractions, solutions of sodium hydroxide at approximately pH 11.5 removed up to 57% of arsenic from sand fractions containing initial concentrations of around 100 mg/kg; sodium carbonate solutions gave similar results but required significantly higher reagent doses. A strong dependency on pH was shown in the leaching tests and there was no evidence that leaching performance was constrained by arsenic solubility. A batch extraction test examining relative leaching efficiencies between subfractions of the tested soil showed a slightly better performance for the larger subfraction. No significant improvements in overall leaching performance were observed in simulated countercurrent tests. Further investigation of washing process configuration, solids hold-up times, temperature, and aqueous extract treatment/recycling will need to be completed to decide if a leaching step should be included as part of a soil washing treatment application.

5.5 Conclusions and Recommendations

This section summarizes the conclusions from the various treatability studies relating to the viability assessment of physical screening/soil washing with dissolution.

5.5.1 Soil Characterization

The TCLP results for lead and arsenic obtained for the treatability samples indicate that most Site soils do not exhibit a RCRA hazardous toxicity characteristic associated with these metals.

Physical analysis data show that the Site soils are moderately well sorted (i.e., more coarse fraction and a relatively low silt/clay content), non-plastic, and classify as sand and sandy-loam. Excavation and materials handling of the soils should be relatively easy using conventional equipment and methods, and the soils should be amenable to processing by physical screening and mixing equipment.

The Site soils are essentially neutral and possess little acidic or basic buffering capacity. This is advantageous for both solidification/ stabilization and soil washing with dissolution processes in that the amounts of binder or leaching chemical needed to achieve the desired treatment performance will be minimized. The unamended soils will not be corrosive to excavation, materials handling, or processing equipment.

Based on speciation analysis data, soil lead is present mainly as carbonate, specifically adsorbed and ion-exchangeable forms, and in association with iron and manganese oxides and organic material. Lead constituents are present both in association with soil surfaces (surface bonding/binding) and as free metallic particles within the soil matrix. Arsenic speciation analysis data show that soil arsenic exists predominantly as arsenate (+5 valence state) and occurs mostly in association with iron oxides and the organic portion of the soil. Arsenic bonding and binding is primarily associated with the smaller soil particles with a high surface area per unit mass.

Leaching data show that both lead and arsenic are essentially insoluble and immobile under normal environmental conditions. Under both acidic and basic leaching conditions, soil lead can be leached (more readily mobilized under the former), although some extremely leach-resistant forms of lead are indicated. Soil arsenic can be readily mobilized under moderately basic leaching conditions but is difficult to remove at low pH. This is consistent with the information yielded by the lead and arsenic speciation analyses.

The Site soils have a low organic carbon content and so no interference or inhibitory affects associated with potential carbon-heavy metal bonding/binding would be expected for either solidification/stabilization or physical screening/soil washing with dissolution treatment.

5.5.2 Volume Reduction

For both lead and arsenic, significant proportions of these constituents were measured in the silt/clay fraction of the soil. Separation of the fines from the whole soil would be effective in concentrating a substantial proportion of the metals into a relatively small soil volume. This will potentially reduce the volume of significantly impacted soils requiring subsequent treatment or disposal.

A comparison of soil particle distribution and associated chemical distribution data with remediation and cleanup levels was made. The results indicated that recovery, as “clean soil”, of the cobbles and gravel fraction (40% to 60% of soil by weight) can be achieved by dry and wet screening, respectively. More aggressive soil washing and secondary treatment can achieve recovery of the sand, cobble, and gravel fractions (90% or more of soil by weight) as "clean" material.

5.5.3 Metal Dissolution/Removal

Strong hydrochloric acid or perchloric acid solutions at low pH (approximately pH 1) are effective at significantly reducing lead concentrations in the Site soils. Similar leaching performances can be achieved with these acids at more moderate pH (approximately pH 3) if a chelant (EDTA) is added to the leaching solution.

In the case of arsenic-impacted soils, strong sodium hydroxide and sodium carbonate solutions (approximately pH 12 or greater) are able to effectively remove arsenic in a single-stage batch extraction regime. Leaching performance does not appear to be constrained by arsenic solubility, and might be improved under a multi-stage countercurrent leaching process configuration.

The use of acidic/caustic leaching in conjunction with physical screening processes is indicated to have potential for reducing concentrations of lead and arsenic in the sand fraction of the soil or in the sands and fines combined. This approach merits further evaluation.

Table 5-1 - Soil Characterization Parameters by Treatment Technology

Soil	Treatment Technology	Test Types
Whole Soil and Fractions	Stabilization/Solidification	GANC/RGANC MANC/RMANC Total Carbon, Inorganic and Organic Carbon RCRA Appendix IX SemiVOCs TCLP (inorganic and semiVOCs) Moisture Content Speciation Analysis of Fractions
	Physical Screening/Soil Washing for Dissolution	Constituent Distribution with Particle Size Surface Area Calculations Silt/Clay Content MANC/RMANC during GANC/RGANC Organic Carbon Speciation Analysis of Fractions Atterberg Limits
	Smelting/Thermal Recovery	Total Constituent Concentration Constituent Distribution with Particle Size XRF Scan (mineralogy) Silica Content (by XRF) Moisture Content Total Carbon RCRA F039 Listed Metals

Abbreviated terms used in this table are defined in Appendix B.

353415\5-1.tbl

Table 5-2 - Soil Characterization Parameters by Category

Soil	Category	Information Use	Test Types
Whole Soil	Physical Handling	Provides information on how soil will behave during excavation and in treatment processes.	Surface Area Calculations (Lead only) Particle Size Distribution Soil Plasticity (Atterberg Limits) USDA Soil Classification Density (loose and packed) Moisture Content
	Regulatory	Provides information to enable regulatory waste code classification.	Total Constituent Concentration TCLP Constituent Concentrations RCRA Appendix IX Total Metal Concentration TCLP (inorganics and semiVOCs) RCRA Appendix IX Inorganics RCRA Appendix IX SemiVOCs pH
	Soil Chemistry	Provides information on contaminant/soil interactions to further general understanding of soil properties and used in evaluating treatment technologies.	Bonding/Binding Anions Soluble Cations Carbon (total/inorganic/organic) GANC/RGANC
	▸ Anions	Provides an indication of availability of bonding/binding sites for heavy metals (anions can combine with metals to form low solubility salts)	Sulfide Sulfate Phosphate Carbonate/Bicarbonates
	▸ Soluble Cations	Can compete with heavy metals for bonding/binding sites (ion-exchange sites, anions).	Calcium Sodium Magnesium Potassium Manganese Iron
	▸ Carbon Balance	Organic carbon can bond/bind with metals.	Total Carbon Inorganic (fixed) Carbon (by TGA) Organic Carbon (by difference)

Table 5-2 - Soil Characterization Parameters by Category

Soil	Category	Information Use	Test Types
Whole Soil, Continued	▸ Alkalinity/Acidity, Buffering Capacity	Provides indications of how soil will respond to acid/base changes.	pH Redox GANC/RGANC
	Mobility and Leachability	Provides information on mobility in, and availability to, the environment.	TCLP (inorganics and semiVOCs) Equilibrium Leaching Procedure (lead only) (SAR-F039 List Metals) MANC during GANC/RGANC GANC/RGANC
Soil Fractions	Regulatory	Provides information on metals of regulatory concern to enable proper management/disposal.	F039 List Metals
	Soil Chemistry	Provides information on contaminant/ soil interactions to further general understanding of soil properties and used in evaluating treatment technologies.	Cation Exchange Capacity (CEC) (Lead only) Total Iron and Manganese Total Chloride
	Speciation	Provides information on what specific chemical forms of metals are present and how metals are bound within soil. Aids in determination of impact to environment and technology selection.	Sequential Extraction Scanning Electron Microscopy (SEM) X-Ray Diffraction (XRD) X-Ray Fluorescence (XRF) - Mineralogy

Abbreviated terms used in this table are defined in Appendix B.

Table 5-3 - Summary of Treatability Studies

Type of Study	Organization Performing Treatability Study	Location of Study	Target Constituent	Summary of Scope	Areas of Site Sampled
Soil Characterization	Hazen Research, Inc.	Golden, CO	Lead and Arsenic	Complete characterization (see Table 5-1 and Table 5-2)	7, 18, 36, 40, 18, 36, NGRR, Hot Spot Soils
Soil Washing/Leaching	Department of Civil Engineering, State University of New York	Buffalo, NY	Lead	Test various extraction agents and leaching conditions to remove lead	40
Constituent Speciation	Battelle Pacific Northwest Laboratories	Sequim, WA	Arsenic	Identify ionic and organic species of arsenic	5, 25, 36, NGRR
Wet Screening	Hart Crowser, Inc.	Seattle, WA	Arsenic	Determine distribution of arsenic between soil size fractions	18, 36, NGRR
Soil Leaching	Weyerhaeuser Analytical and Testing Services	Federal Way, WA	Arsenic	Test potential of non-proprietary leaching solutions for removal of arsenic	18, NGRR

Note: NGRR = Narrow Gauge Railroad Track

Additional Studies Performed but not considered during evaluation of technologies

Type of Study	Organization Performing Treatability Study	Location of Study	Target Constituent	Summary of Scope	Areas of Site Sampled
Solidification/ Stabilization	Center for GeoEnvironmental Science & Technology, University of Cincinnati	Cincinnati, OH	Lead and Arsenic	Evaluate ability of 3 types of binding mixes to stabilize lead and arsenic	36, 40

HCl/0.005M EDTA	1	25	20:1	607 ± 145 (5)	0.37 ± 0.29 (3)
HCl/0.01M EDTA	3	25	20:1	644 ± 53 (5)	0.67 ± 0.14 (3)
HCl/0.01M EDTA	3	50	20:1	1045 ± 171 (4)	1.17 ± 0.14 (3)
HCl/0.01M Salicylate	3	25	20:1	1248 ± 147 (4)	

Notes:
The soil extractions were completed in a 24-hour batch extraction.

Remaining soil lead concentrations are given as the mean ± 95% CL (number of readings), after 24 hours of batch washing, with measurement outliers omitted. Readings were considered to be outliers if their values were greater than the initial lead concentration of 1,401 mg/kg.

The maximum proportion of lead released by soil washing during these experiments was 68 percent, achieved with HCl as the extractant at a pH = 1, at 25 degrees centigrade, and a 10:1 liquids:solids ratio.

Chapter 6 – DEVELOPMENT AND SCREENING OF ALTERNATIVES

6.1 Introduction

This chapter combines the technologies and process options, retained from the Chapter 4 screening, into working remedial alternatives. These alternatives are further screened by evaluating to what degree the alternatives can reduce the potential for exposure identified in the RA. Each alternative was evaluated for all remediation units. Those alternatives that meet the screening criteria and can be effectively applied to Site soils were retained for detailed analysis in Chapter 7. The remedial alternatives applicable to Miscellaneous Small Remediation Units are described in Section 8.3.

Section 6.2 describes the alternative screening criteria. Section 6.3 assembles the technologies and process options retained from Chapter 4 into remedial alternatives. Section 6.4 describes and screens each alternative, and Section 6.5 ranks the alternatives based on the outcome of the screening process. Section 6.6 presents a summary of the alternatives retained for detailed analysis in Chapter 7.

6.2 Screening Criteria

Like the initial technology screening, alternative screening was based on three criteria: effectiveness, implementability, and cost (as described in Section 4.3.3). Figure 6-1 shows the relationship between these three screening criteria and the eight MTCA evaluation criteria used in the detailed analysis of alternatives in Chapter 7. Unlike the initial technology screening, the relative importance of the criteria are different, with more emphasis on the effectiveness of the alternative in attaining the RAOs and cleanup standards and less emphasis on implementability and cost. Effectiveness was emphasized because it encompasses five of the seven evaluation criteria used in Chapter 7 and because MTCA guidance places particular importance on permanence, one of the sub-criteria of effectiveness.

6.2.1 Effectiveness

For alternative screening, effectiveness is the primary criterion. Key sub-criteria (of effectiveness) used in the screening of alternatives are listed below. The protection of human health and the environment, and compliance with cleanup standards as listed in WAC 173-340-700 and/or WAC 173-340-7490(6)(f) are "threshold criteria" since they must be met by the alternative for it to be retained for further evaluation in Chapter 7. Those alternatives that did not meet these threshold criteria (with the exception of No Action) were not retained for further evaluation. The sub-criteria of effectiveness used to assess effectiveness are defined as:

Protectiveness: This evaluation considers the overall protection each technology provides to human health and the environment including the degree to which existing risks are reduced, the time required to reduce risk and obtain cleanup standards, the off-Site and on-Site risks resulting from the implementation of the alternative and the degree of improvement of the overall environmental quality.

Permanence: This evaluation considers the degree to which the alternative permanently reduces the toxicity, mobilization or volume of the contaminants including the adequacy of the alternative/technology in reducing or elimination of releases of the contaminant, degree to which the treatment is irreversible, and the characteristics and quantity of the treatment residuals generated. Since lead and arsenic are the contaminants of concern, one of the MTCA criteria, destruction, is not obtainable by any of the listed alternatives and will not be evaluated.

Long-Term Effectiveness: This evaluation considers the effectiveness and reliability of the process during the time when contaminant concentrations remain on site that are greater than cleanup levels including the magnitude of risk with the alternative in place, the degree of certainty that the alternative/technology will be successful, and the adequacy and reliability of any Site controls.

Management of Short-Term Risks: This evaluation considers the effectiveness of the process dealing with the potential impacts to human health and the environment during the construction and implementation phase and the effectiveness of the measures to manage such risks.

6.2.2 Implementability

Implementability includes both operational implementability and administrative feasibility. Operational implementability refers to the ability to construct and reliably operate the remediation alternative. It includes operation, maintenance, replacement, and monitoring of the technical components of an alternative. Administrative feasibility refers to the ability to obtain approvals from city/county/state officials/agencies, the availability of treatment, storage, and disposal services, and the availability of specific equipment.

6.2.3 Cost

The alternatives screening cost estimates were developed from a variety of sources including technology unit costs developed by the project team, vendor information, published cost-estimating guides, and prior experience with similar technologies. In this evaluation, treatment includes construction and treatment activities necessary for attaining the RAOs. The screening level cost estimates do not include the contingency, administration, maintenance, or long-term monitoring costs since these costs will not impact the relative cost differences between alternatives unless the alternative does not include long-term monitoring. These cost estimates are used for the screening of the alternatives only and should not be considered to represent the total remediation cost associated with the cleanup of the Site. Estimated costs presented in this chapter represent the direct cost that would be realized if the alternative being evaluated were implemented to address the total volume of contaminated soil listed in Chapter 3. Table 6-1 lists these costs. Chapter 7 presents the potential total costs for implementation of the alternatives that were retained for the detailed analysis.

6.2.4 Consideration of Public Concerns

MTCA calls for the evaluation of local community potential concerns over the alternative and how the alternative addresses those concerns. For this FS it has been determined that with the exception of the No Action Alternative, each of the remaining alternatives share the common public concerns of protection of cultural and historical sites and artifacts, long-term public health, and short-term public health. The latter two are key components of Long-Term Effectiveness and Management of Short-Term Risks and will be addressed under those headings. A cultural resource protection program has been in place at the Site for many years and will be followed during the cleanup. The cultural protection plan will also be a key component of the Cleanup Action Plan for this site. Since the same amount of soil excavation will be required, little, if any, difference exists between the action-related alternatives in addressing cultural resource concerns. As such, we will focus on concerns that are unique to each alternative but not those that are “global” in nature.

6.2.5 Ecology Cleanup Technology Preference

Ecology summarizes its cleanup technology preference guidance for the selection of remedial alternatives in WAC 173-340-350 (8)(c)(i)(C). The guidance sets a relative ranking for technologies. The following technologies are listed in order of descending preference by Ecology:

- Reuse or recycling;
- Destruction or detoxification;
- Separation or volume reduction, in combination with reuse, recycling, destruction, or detoxification;
- Immobilization;

- On-Site or off-Site disposal;
- On-Site isolation or containment; and
- Institutional controls and monitoring.

6.3 Assembly of Alternatives - Groundwater

Two alternatives have been selected for the remediation of groundwater; natural restoration and active groundwater treatment. Chapter 7 will further evaluate these alternatives and describe the preferred alternative.

6.3.1 Description and Screening of Alternatives – Groundwater

Active Groundwater Treatment: Available technologies for the active treatment of impacted groundwater are very limited and would require, for this Site, the pumping of very large quantities (up to 7,000 gallons per minute) of water. Groundwater pump and treat is the only active groundwater remediation technology which could be applied at the Site for the following reasons:

- Groundwater which would be targeted for remediation is deep (100 to 200 feet below surface) and laterally extensive. preventing use of impermeable barriers, gates, or other groundwater isolation techniques;
- DNT (the single contaminant) has low volatility, preventing use of sparging or other venting technologies ;
- Although DNT can be degraded through natural in situ processes, only biological degradation could potentially occur in Site aquifers and attempting to enhance this process as part of a remediation program would likely be infeasible;
- DNT readily degrades by photolysis (half-life on the order of days; Etnier, 1987), but this process will not occur in aquifers;
- DNT can be transformed to formic and acetic acids, but only at temperatures at which water would not persist (520°F; Etnier, 1987); and
- DNT in water degrades through biological processes under some aerobic and anaerobic conditions (Spanggord. 1980; Etniert 1987), but the metabolism of DNT is strongly dependent on environmental conditions and the presence of viable microorganisms (ATSDR, 1989). Biodegradation of DNT may be occurring naturally in Site aquifers, yet attempting to establish or enhance appropriate natural microorganism populations (e.g. , by introducing nutrients) in Site aquifers would likely be infeasible because of the size of the Site and the substantial depth of the aquifers.

Natural Restoration: Natural restoration is the process in which the source of the contamination is removed and the water is left to clean itself up naturally. Active monitoring is typically a part of natural restoration.

6.4 Assembly of Alternatives - Soil

This FS defines alternatives for soils as a collection of technology process options that can be combined to effectively address a given remediation unit. In general, technologies/process options that are effective for one remediation unit are also effective for other remediation units. There are some exceptions to this; for example, the alternate chosen in ecologically or historically sensitive areas may not be the same as those within industrial or commercial areas.

Based on the initial screening of technologies (presented in Chapter 4) and the results of the treatability studies (presented in Chapter 5), the following alternatives were formulated and ranked independently for all remediation units:

- No Action;
- Capping;
- Cover;
- Cap/Cover;
- On Site Deposition, Cap and Cover;
- Off-Site Disposal at a Landfill;
- Wet Screening, Classification, and Disposal of the Residual Soils at a Landfill;
- Wet Screening with On-Site Deposition, Cap and Cover and Disposal of the Residual Soils at a Landfill;
- Wet Screening with Stabilization and On-Site Deposition and Cover;
- Soil Washing with Wet Screening, Classification, Acid/Base Extraction, and Disposal of the Residual Soils at a Landfill; and
- Soil Washing with Wet Screening, Classification, Chelant Extraction, and Disposal of the Residual Soils at a Landfill.

Ten potential remedial alternatives, in addition to No Action, were developed for the Site. Each alternative will attain varying degrees of risk reduction under the proposed land use plan.

6.5 Description and Screening of Alternatives

This section presents a brief description of each alternative and discusses the performance of each alternative against the three screening criteria. Alternatives which are most likely to attain the RAOs are identified for further evaluation in Chapter 7.

6.5.1 No Action

No action means that no remedial activities will be implemented to clean up the Site.

Effectiveness:

- Protectiveness: The No Action alternative does not attain the Site ecological or human health standards. As such this alternative will not meet cleanup standards as listed in either WAC 173-340-700 or WAC 173-340-7490(6)(f). Since no action would occur there would be no reduction in risk.
- Permanence: No action does not reduce toxicity, mobility or volume and is not a permanent solution.
- Long Term Effectiveness: Since this alternative does not attain cleanup standards or reduce risk, toxicity or mobility it is not effective over the long-term.

- Management of Short Term Risks: Since no activities occur under this alternative, short-term risks associated with implementation would not occur.

- Consideration of Public Concerns: No action would result in denied access to the Site. Development of commercial, historical and golf course land use areas would not be allowed by this alternative.

Implementability: This alternative does not meet the needs of the current Site development plans or Ecology's cleanup standards. Development of commercial, historical and golf course land use areas would be limited by this alternative. Since no construction activities will be required as part of this alternative, it could be readily implemented.

Cost: There is no initial remediation cost associated with the implementation of this alternative since no activities are performed.

Considerations: No Action does not have the ability to meet RAOs consistent with Ecology's ecological and human health standards but has the lowest initial cost. It was retained during the detailed analysis to provide comparison with other remedial alternatives.

6.5.2 Capping

Capping consists of the installation of a layer of highly durable, impermeable, engineered materials over the Site soils containing contaminant concentrations above the CL but below the RL. No excavation of soils would occur as part of this alternative.

Effectiveness:

- Protectiveness: Both Site wide and discrete area capping could meet cleanup standards as listed in WAC 173-340-7490(6)(f). Preventing direct contact exposure with soil above the CL would significantly reduce risk. The time frame for this action would be dependant upon the size of the area capped. Capping of the entire Site would require approximately 3.3 years. Off-Site risk would be limited to implementation (see Management of Short Term Risks) and ongoing on-Site risks would be minimal. The reduction in exposure risk would improve the overall environmental condition of the Site.

- Permanence: There would be no reduction in toxicity or volume. Mobility would be reduced due to the impermeable nature of the Cap material. Capping does not represent a permanent remedy.

- Long Term Effectiveness: Once complete, capping would greatly reduce residual risk. Long-term effectiveness of a capping remedy relies on an effective O&M program. Such programs can be effective with active management.

- Management of Short Term Risks: Since this alternative does not include the excavation of contaminated soils, short term exposure risk would be less than excavation related alternatives.

- Consideration of Public Concerns: Large scale capping would not meet the public's wish to return the property to viable use or Weyerhaeuser Real Estate's plans to develop the property. Lesser scale application could meet all concerns.

Implementability: Site wide capping could potentially result in limiting land use and development in the capping area. This alternative does not meet the current needs of the Site development plans. Capping is a common remedy and could be applied. Small-scale applications could be effectively implemented.

Cost: A direct cost range of $79 million (M) to $129.6M is estimated for implementation of this alternative. Long-term cap maintenance costs would also be incurred.

Considerations: Capping would be effective in meeting the RAOs for the Site but is not permanent. Capping also may restrict future Site development. It could be considered in small-scale areas where roads, asphalt trails, parking areas, or buildings are planned. It is also costly to apply. This alternative may have some limited use and will be retained for further evaluation in Chapter 7.

Adjustments to remediation levels: No adjustments to the remediation levels used in the RA are warranted for this alternative.

6.5.3 Cover

A cover involves the installation of a clean soil layer over areas of the Site that contain soil with concentrations of constituents above the CL but below the RL. The installation of a cover over these soils may meet the RAOs by reducing direct contact exposure. At a minimum the cover would equal 18 inches in depth for the protection of human health and 6 inches in depth (gravel only) for the protection of ecological receptors. No excavation of soils would occur as part of this alternative.

Effectiveness:

- Protectiveness: Both Site wide and discrete area cover could, depending on the thickness of the cover, meet cleanup standards as listed in WAC 173-340-7490(6)(f). Preventing direct contact exposure with soil above the CL would significantly reduce risk. The time frame for this action would be dependent upon the size of the area covered. Covering of the entire Site would require approximately 2.4 years. Off-Site risk would be limited to implementation (see Management of Short Term Risks) and ongoing on-Site risks would be minimal. The reduction in exposure risk would improve the overall environmental condition of the Site. The placement of a topsoil cover in golf course, treeless open space, and historical land use areas could, depending on thickness, be an effective exposure barrier.

- Permanence: Cover, in itself, does not represent a permanent remedy. There would be no reduction in mobility, toxicity or volume.

- Long Term Effectiveness: The residual risk would be greatly reduced once a complete cover was in place. Long-term effectiveness of a cover remedy relies on an effective O&M program. Such programs can be effective with active management.

- Management of Short Term Risks: Since this alternative does not include the excavation of contaminated soils, short term exposure risk would be less than excavation related alternatives.

- Consideration of Public Concerns: Total Site cover would not meet the public's wish to return the property to viable use or Weyerhaeuser Real Estate's plans to develop the property. Lesser scale applications could meet all concerns.

Implementability: This alternative can meet the current needs of the Site development plans in areas where treeless open space, historical, or golf course land uses are planned. Installation of a soil cover across broad areas may be difficult to implement because of development restrictions in the covered area and the availability of cover material. Cover over smaller areas can be easily completed since smaller quantities of soils are readily available on Site and can be placed easily because of the typically flat topography of the Site.

Cost: A direct cost range of $43M to $72M is estimated for implementation of this alternative. Clean soil from on-Site sources makes the cost less for installation of soil cover in selected areas.

Considerations: Cover would be effective in meeting the RAOs for the Site, but is not permanent. Cover would also restrict future Site development. It could be considered on a small-scale in areas of environmental or historic sensitivity. As such, it was retained for further evaluation in Chapter 7.

Adjustments to remediation levels: No adjustments to the remediation levels used in the RA are warranted for this alternative.

6.5.4 Cap/Cover

Cap/Cover consists of the placement of 18 inches of soil over the Site soils containing contaminant concentrations above the CL but below the RL. The cap would consist of a layer of high durability, engineered materials or layer of gravel. A 12-inch to 18-inch soil cover would then be placed on top of the cap to further prohibit exposure to the underlying soils. The installation of the cap/cover would meet the RAOs by preventing direct contact exposure with soil above the CL. This combination would act as an exposure barrier to both ecological receptors and humans. No excavation of soils would occur as part of this alternative.

Effectiveness:

- Protectiveness: Cap/Cover could meet cleanup standards as listed in WAC 173-340-7490(6)(f) in both Site wide and smaller applications. Since cap/cover incorporates the best of both the cap and cover alternatives risk would be further reduced. The time frame for this action would be dependent upon the size of the area capped. Cap/Cover of the entire Site would require approximately 2.8 years. Off-Site risk would be limited to implementation (see Management of Short Term Risks) and ongoing on-Site risks would be minimal. The reduction in exposure risk would improve the overall environmental condition of the Site.

- Permanence: There would be no reduction in toxicity or mobility. This alternative does not represent a permanent remedy.

- Long Term Effectiveness: The residual risk would be greatly reduced once a complete cover was in place. Long-term effectiveness of a capping remedy relies on an effective O&M program. Such programs can be effective with active management.

- Management of Short Term Risks: Since this alternative does not include the excavation of contaminated soils, short term exposure risk would be less than excavation related alternatives

- Consideration of Public Concerns: Large-scale cap/cover would not meet the public's wish to return the property to viable use or Weyerhaeuser Real Estate's plans to develop the property. Restricting the use of this alternative to the golf course, open space, and historical land use areas would meet all concerns.

Implementability: Large scale capping could potentially result in limiting land use and development in the capped area. This alternative does not meet the current needs of the Site development plans. Isolated use of this alternative could be useful in preventing exposure to soil with contaminant concentrations above CLs. Capping is a common remedy and could be applied.

Cost: A direct cost range of $26.6M to $41.5M is estimated for implementation of this alternative. Long-term cap maintenance costs would also be incurred.

Considerations: Cap/Cover would be effective in meeting the RAOs for the Site, but is not permanent. Cap/Cover would also restrict future Site development and could be considered in golf course, historical areas and open space areas where exposure prevention and protection of habitat are desired. As such, it was retained for further evaluation in Section 7.

Adjustments to remediation levels: The risk-based remediation or cleanup levels used in the RA for soil located within the golf course and open space land use areas are based on frequency of exposure and do not consider the installation of a soil cover over impacted soil. The application of an engineered cap/cover will further reduce the potential risk of exposure thereby increasing the effective RL. Ecology has determined that the effective remediation levels for lead- and arsenic-contaminated soils in areas of

the Site that will have a cap/cover are 4,100 mg/kg and 530 mg/kg, respectively. Justification of this decision is included in Appendix H.

6.5.5 On Site Deposition, Cap and Cover

On-Site Deposition, Cap and Cover includes the excavation of soils containing contaminant concentrations above the RL in one land use, transferring it to a land use area within the area of contamination (AOC) where it is below the RL for that land use, and using a cap/cover combination to prevent exposure. The cap would consist of a layer of high durability, engineered materials or layer of gravel over the deposited soils. A soil cover would then be placed on top of the cap to further prohibit exposure to the underlying soils. The installation of the cap/cover would meet the RAOs by preventing direct contact exposure with soil above the CL. Implementation of this alternative allows integration of the deposition of soil with the design of the golf course.

Effectiveness: On-Site deposition with cap/cover is allowed under MTCA and may be effective in meeting site cleanup standards and RAOs. Although volume and toxicity are not modified, soil would be placed in a land use area where the exposure risks are reduced based on restricted access and the protection afforded by the cap/cover.

- Protectiveness: This alternative would meet cleanup standards as listed in WAC 173-340-7490(6)(f). Risk would be reduced in two ways. The cap/cover would prevent direct exposure and the consolidation of the contaminated soils in a smaller area would lessen the probability of direct contact. The timeframe necessary to complete this action is approximately 2.8 years.

- Permanence: There would be no reduction in toxicity, or mobility. This alternative does not represent a permanent remedy.

- Long Term Effectiveness: Once complete this alternative would greatly reduce residual risk. Long-term effectiveness of a capping remedy relies on an effective O&M program. Such programs can be effective with active management. This alternative is particularly applicable within the golf course land use areas since the operations of a golf course would ensure the competence of the cap/cover.

- Management of Short Term Risks: Since this alternative includes excavation, it represents an increased risk when compared to non-excavation alternatives. It does represent the least risk of the alternatives that involve excavation. An aggressive dust control program and air monitoring could minimize short-term risks. These efforts have been successful in the past in controlling potential risks.

- Consideration of Public Concerns: This alternative would meet the public's wish to return the property to viable use and WRECO's plans to develop the property. Restricting the use of the alternative to the golf course land use areas would meet all concerns.

Implementability: If restricted to the golf course this alternative can meet the current needs of the Site development plans and can be easily implemented using conventional soils excavation, handling, and transportation equipment. Since the AOC has been defined by Ecology as the land inside the Consent Decree Boundary, soil could be deposited in areas where future Site development would not be restricted.

Cost: An approximate direct cost of $13M to $21.6M is estimated for implementation of this alternative. Clean soil from on-Site sources makes the cost of installation of a soil cover low.

Considerations: This alternative provides for placing soil in land use areas associated with lower exposure risks. This alternative would also consolidate the contaminated soils into discrete areas, and thus is more effective than wholesale covering or capping of the Site. Soil cover may restrict future Site

development but not to the degree that whole cover or capping would. The volume of impacted soil would not be reduced.

Adjustments to remediation levels: A key component of this alternative is the installation of an 18-inch soil cap/cover (as described in Section 7.2.3) The risk-based remediation or cleanup levels used in the RA for soil located within the golf course and open space land use areas are based on frequency of exposure and do not consider the installation of a soil cover over impacted soil. The application of an engineered cap/cover will further reduce the potential risk of exposure thereby increasing the effective RL. Ecology has determined that the effective remediation levels for lead- and arsenic-contaminated soils in areas of the Site that will have a cap/cover are 4,100 mg/kg and 530 mg/kg, respectively. Justification of this decision is included in Appendix H.

6.5.6 Offsite Disposal at a Landfill

This option involves excavation of soil above the CLs, transport, and off-Site disposal. Soil would be characterized based on RI and confirmation sample results.

Effectiveness:

- Protectiveness: Off-Site disposal would be effective in meeting the cleanup standards for the Site as listed in WAC 173-340-700. The timeframe necessary to complete this action is approximately 7.6 years.

- Permanence: Since no soil exceeding the cleanup standards would remain on-Site, volume and toxicity would be reduced on-Site but not at the disposal facility. This alternative represents a permanent solution.

- Long Term Effectiveness: This alternative is effective for the Site. Soil would have to be managed at the disposal facility over the long-term.

- Management of Short Term Risks: This alternative would involve the greatest amount of excavation and hauling of any of the retained alternatives. As such, the risks from dust and truck traffic would increase proportionally. An aggressive dust control program and air monitoring could minimize short-term risk to dust exposure. These efforts have been successful in the past in controlling potential risks. The high volume of truck traffic could cause a significant amount of added risk.

- Consideration of Public Concerns: Trucking of the soil off-Site would require approximately 44,000 truckloads over 5.6 years. Truck traffic has been an issue with the public in the past.

Implementability: This alternative can meet the current needs of the Site development plans. It can be implemented using standard excavation practices.

Cost: A direct cost range of $181M to $248.8M is estimated for implementation of this alternative.

Considerations: This alternative represents the highest reasonable cost for remediation of the Site. Implementing more costly alternatives to remediate the Site would not be warranted. No volume reduction would be attained by this alternative. It is, however, the most permanent and will be retained for further evaluation in Chapter 7.

Adjustments to remediation levels: No adjustments to the remediation levels used in the RA are warranted for this alternative.

6.5.7 Wet Screening, Classification, and Disposal of the Residual Soils at a Landfill

This option includes the excavation of soil above CLs, wet screening the soil into at least two soil fractions, and deposition of the clean coarser fraction on the Site. The concentrated finer fractions would be disposed of at a landfill. The results of the 2001 Screening Program and an evaluation of the treatability study data, presented in Chapter 5, indicates that the cut point for generating a clean coarse fraction and a concentrated finer fraction will depend on the initial contaminant concentration in the soil. For the purposes of evaluation, this FS considered this cut point to be ½ inch. As such, total volume of soil requiring off-Site disposal is likely to be approximately 76 percent. The residual soil could require stabilization at the landfill. No on-Site deposition of soils above the CLs would occur under this alternative. No cover or cap would be used.

Effectiveness:

- Protectiveness: Classification and off-Site disposal could be effective in meeting the cleanup standards for the Site as listed in WAC 173-340-700. The timeframe necessary to complete this action is approximately 4.4 years.

- Permanence: Since no soil exceeding the cleanup levels would remain on Site, volume and toxicity would be reduced on-Site but not at the disposal facility. This alternative represents a permanent solution.

- Long Term Effectiveness: Since all soil contaminant concentrations on-Site would not exceed cleanup standards, this alternative would be effective long-term. Soil shipped off-Site would have to be managed at the disposal facility over the long-term.

- Management of Short Term Risks: All wet screening and soil washing alternatives represent an increase in materials handling compared to other retained alternatives. As such, the risks from dust increase proportionally. An aggressive dust control program and air monitoring could minimize short-term risk to dust exposure. These efforts have been successful in the past in controlling potential risks.

- Consideration of Public Concerns: Trucking of the soil off-Site would require approximately 34,000 truckloads over 4.0 years. Truck traffic has been an issue with the public in the past.

Implementability: This alternative could be implemented using existing soil treatment and handling technologies. Disposal of contaminated fines soil at a landfill could be implemented but would require up to 34,000 truckloads. Based on data from 2001 Screening Program, water generated by the wet screening process could be filtered to remove suspended contaminants and recycled.

Cost: A direct cost range of $61.9M to $110.6M is estimated for implementation of this alternative. As a conservative approach, it was assumed that the residual material would require stabilization at the landfill. Wet screening and a classification cut point of ½ inch (24 percent volume reduction) were used in the cost evaluation.

Considerations: This alternative has the potential for significant soil volume reduction, is permanent and uses conventional soil handling technologies. It is, however, a time consuming and expensive process that would cause significant public concern (truck traffic). Since the time, benefit and increased public concern outweigh the benefits (vs. similar volume reduction alternatives) it will not be retained for further evaluation.

Adjustments to remediation levels: No adjustments to the remediation levels used in the RA are warranted for this alternative.

6.5.8 Wet Screening with On Site Deposition, Cover and Cap and Disposal of the Residual Soils at a Landfill

This option includes the excavation of soil above Site-specific RLs, wet screening the soil to separate it into "clean" and contaminated fractions, off-Site disposal of the contaminated fines, and the deposition and cover/cap of the clean, coarser fraction on the Site.

Wet screening the soil into two soil fractions, one larger and one smaller than about -200 mesh, will generate a clean coarser fraction and a concentrated finer fraction which could be disposed of at a landfill. Since the finer fraction of soil from the wet screening operation will contain higher concentrations of lead or arsenic than the excavated, untreated soil, stabilization may be required at the landfill. The results of the 2001 Screening Program indicates that the total volume of soil requiring off-Site disposal is likely to be less than 10 percent.

The coarse "clean" fraction would be transferred to discrete locations within the golf course land use areas and covered with an 18-inch thick cap/cover combination to prevent exposure. The cap would consist of a layer of high durability, engineered materials or layer of gravel placed over the deposited soils or soils which contain contaminant concentrations above the CL but below the RL. A soil cover would then be placed on top of the cap to further prohibit exposure to the underlying soils. The installation of the cap/cover would meet the RAOs by preventing direct contact exposure with soil above the CL.

Effectiveness:

- Protectiveness: This alternative could be effective in meeting the cleanup standards for the Site as listed in WAC 173-340-700. Although mobility and toxicity are not modified, volume would be reduced and the soil would be placed in a land use area where the exposure risks are reduced. The timeframe necessary to complete this action is approximately 3.6 years.

- Permanence: There would be no reduction in toxicity or mobility. This alternative is not a permanent remedy.

- Long Term Effectiveness: Once complete, this alternative would greatly reduce residual risk. Long-term effectiveness of a cap/cover remedy relies on an effective O&M program. Such programs can be effective with active management. This alternative is particularly applicable within the golf course land use areas since the operations of a golf course would ensure the competence of the cap/cover.

- Management of Short Term Risks: All wet screening, and soil washing alternatives represent an increase in materials handling compared to other retained alternatives. As such, the risks from dust increase proportionally. An aggressive dust control program and air monitoring could minimize short-term risk to dust exposure. These efforts have been successful in the past in controlling potential risks.

- Consideration of Public Concerns: No additional public concerns are anticipated.

Implementability: If on-Site deposition is restricted to discrete areas within the golf course land use area, treeless open space, and historical land use areas this alternative can meet the current needs of the Site development plans and can be easily implemented using conventional soils excavation, handling, and transportation equipment.
Cost: A direct cost range of $59.9M to $99M is estimated for implementation of this alternative.

Considerations: This alternative has the potential for significant soil volume reduction, and uses conventional soil handling technologies. It is a less time consuming and expensive process than similar volume reduction alternatives and would reduce public concern over truck traffic. This alternative provides for placing soil in land use areas associated with lower exposure risks. Future Site development restrictions due to soil covers may be limited to the golf course areas only. Since this alternative has

benefits in time, cost and decreased public concern (vs. similar volume reduction alternatives) it will be retained for further evaluation.

Adjustments to remediation levels: A key component of this alternative is the installation of an 18-inch soil cap/cover (as described in Section 7.2.3) The risk-based remediation or cleanup levels used in the RA for soil located within the golf course and open space land use areas are based on frequency of exposure and do not consider the installation of a soil cover over impacted soil. The application of an engineered cap/cover will further reduce the potential risk of exposure thereby increasing the effective RL. Ecology has determined that the effective remediation levels for lead- and arsenic-contaminated soils in areas of the Site that will have a cap/cover are 4,100 mg/kg and 530 mg/kg, respectively. Justification of this decision is included in Appendix H.

6.5.9 Wet Screening with Stabilization and On-Site Deposition and Cap/Cover

This option includes the excavation of soil above the RL, wet screening of the soil, stabilization of the contaminated fraction, and deposition and cover/cap of the clean, coarser fraction on the Site.

Wet screening the soil into two soil fractions, one larger and one smaller than about -200 mesh, will generate a clean coarser fraction and a concentrated finer fraction which would require stabilization prior to deposition. The results of the 2001 Screening Program indicate that the total volume of soil requiring stabilization is likely to be less than 10 percent.

Both the coarse "clean" fraction and the stabilized material would be transferred to discrete areas within the golf course land use areas and covered with an 18-inch thick cap/cover combination to prevent exposure. The cap would consist of a layer of high durability, engineered materials or a layer of gravel over the deposited soils or soils which contain contaminant concentrations above the CL but below the RL. A soil cover would then be placed on top of the cap to further prevent exposure to the underlying soils. The installation of the cap/cover would meet the RAOs by preventing direct contact exposure with soil above the CL.

Effectiveness:

- Protectiveness: Wet screening would be effective in reducing the volume of contaminated soil on Site. It would not lower contaminant concentrations in the fines (the concentration would increase) and thus would not meet the cleanup standards for Site soils. Stabilization of the finer fraction would reduce leachability/mobility and, if placed into a monolithic unit, would reduce the total surface area available for direct contact. The timeframe necessary to complete this action is approximately 3.7 years.

- Permanence: Mobility and volume would be reduced. Toxicity would not be addressed. Since this alternative would not meet cleanup standards, this is not a permanent solution.

- Long Term Effectiveness: This alternative is effective long-term in reducing leachability and, since it is combined with a cover, somewhat reduces the risk of long-term exposure. Long-term effectiveness of a cap/cover remedy relies on an effective O&M program. Such programs can be effective with active management. This alternative is particularly applicable within the golf course land use areas since the operations of a golf course would ensure the competence of the cap/cover.

- Management of Short Term Risks: All wet screening and soil washing alternatives represent an increase in materials handling compared to other retained alternatives. As such, the risks from dust increase proportionally. An aggressive dust control program and air monitoring could minimize short-term risk to dust exposure. These efforts have been successful in the past in controlling potential risks.

- Consideration of Public Concerns: No additional public concerns are anticipated.

Implementability: Both stabilization and wet screening are conventional technologies and the implementation of these technologies in combination would not require special considerations. This alternative can meet the current needs of the Site development plans. Monitoring of the stabilized soil may be required.

Cost: A direct cost range of $46.6M to $84M is estimated for implementation of this alternative.

Considerations: This alternative does not meet cleanup standards and will not retained for detailed analysis.

Adjustments to remediation levels: No adjustments to the remediation levels used in the RA are warranted for this alternative.

6.5.10 Soil Washing with Wet Screening, Classification, Acid/Base Extraction, and Disposal of the Residual Soils at a Landfill

This option includes the excavation of soil above the RL, wet screening the soil at about 4 mesh (6 mm), deposition of the clean coarser fraction on the Site, further classification of the -10 mesh soil to separate a concentrated fine residual fraction (approximately -200 mesh), acid or base extraction of metals from the -10 mesh to +200 mesh fraction, deposition of the cleaned fraction on-Site, and disposal of the -200 mesh fraction at a landfill. Treatability studies indicate that acid extraction of soil containing lead can be attained using an acid mixture with a pH range from 1 to 3. Arsenic is more leachable under base conditions between pH 10 and pH 12. These extraction methods, in combination with classification, may be effective in cleaning impacted soil, and returning about 90 percent of the soil to the Site. Note that a lower classification cut point of 200 mesh (vs. 100 mesh) was selected to enhance metals recovery in the -10 mesh +200 mesh fraction using extraction chemicals. Metals extracted by this alternative would be precipitated and disposed of at a landfill along with non-metal sludge that may accumulate.

Effectiveness:

- Protectiveness: This alternative could be effective in meeting the cleanup standards for the Site as listed in WAC 173-340-700. Soil Washing would be effective in reducing the volume of contaminated soil. Acid extraction would be effective for soils containing lead only, and base extraction would be effective for soils containing arsenic only. No soil above CLs would remain on the Site. The timeframe necessary to complete this action is approximately 5.5 years.

- Permanence: Since no soil above CLs would remain on the Site, this is a permanent solution.

- Long Term Effectiveness: This alternative is effective long-term.

- Management of Short Term Risks: All wet screening and soil washing alternatives represent an increase in materials handling compared to other retained alternatives. Soil washing adds an additional risk associated with the handling of treatment chemicals. As such, the risks from dust increase proportionally. Aggressive chemical handling and dust control programs and air monitoring could minimize short-term risk. These efforts have been successful in the past in controlling potential risks.

- Consideration of Public Concerns: No additional public concerns are anticipated.

Implementability: Soil washing technologies (wet screening, classification, and acid/base extraction) use common processes, and the implementation of these technologies in combination would not require special considerations. This alternative can meet the current needs of the Site development plans and no soil above the RLs would remain on Site. Handling of acids and bases during the treatment process

would require special precautions. No commercial application of base extraction of soils containing arsenic is known.

Cost: A direct cost range of $76.9M to $120M is estimated for implementation of this alternative. The -200 mesh soil and precipitated concentrates (10% of whole soil) would be disposed of off-Site as a characteristic hazardous waste.

Considerations: This alternative has the potential to reduce volume, toxicity, and mobility. Additionally, a low volume of material would require off-Site disposal. Acid/base handling on the Site may reduce the short-term effectiveness. It is, however, a time consuming and expensive process that could also be ineffective short-term due to acid/base handling on the Site. Since these factors outweigh the benefits (vs. similar volume reduction alternatives) it was not retained for further evaluation.

Adjustments to remediation levels: No adjustments to the remediation levels used in the RA are warranted for this alternative.

6.5.11 Soil Washing with Wet Screening, Classification, Chelant Extraction, and Disposal of the Residual Soils at a Landfill

This option includes the excavation of soil above the RL, wet screening the soil at about 4 mesh (6 mm), deposition of the clean coarser fraction on the Site, further classification of the -10 mesh soil to separate a concentrated fine residual fraction (approximately -200 mesh), chelant extraction of metals from the -10 mesh to +200 mesh fraction, deposition of the cleaned finer fraction in the excavation or other on-Site area, and disposal of the -200 mesh fraction at a landfill. Note that a lower classification cut point of 200 mesh (vs. 100 mesh) was selected to enhance metals recovery in the -10 mesh +200 mesh fraction using extraction chemicals. Metals extracted by this alternative would be precipitated and disposed of at a landfill along with any non-metal sludge that may accumulate. Recycling of the extracted metals and -200 mesh fraction may be implemented if this material can meet the strict requirements of the thermal recycling vendors (smelters).

Effectiveness:

- Protectiveness: Soil Washing may be effective in reducing the volume of contaminated soil on site. Chelant extraction has been implemented effectively on soil containing lead. Recent research being performed with soil washing technology indicates that arsenic extraction using a chelant is questionable. The effectiveness of this alternative in treating Site soils with lead or arsenic is therefore uncertain. No soil above cleanup standards would remain on the Site. The timeframe necessary to complete this action is approximately 5.5 years.

- Permanence: Since no soil above CLs would remain on the Site, this is a permanent solution.

- Long Term Effectiveness: This alternative is effective long-term.

- Management of Short Term Risks: All wet screening and soil washing alternatives represent an increase in materials handling compared to other retained alternatives. Soil washing adds and additional risk associated with the handling of treatment chemicals. As such, the risks from dust increase proportionally. Aggressive chemical handling and dust control programs and air monitoring could minimize short-term risk. These efforts have been successful in the past in controlling potential risks.

- Consideration of Public Concerns: No additional public concerns are anticipated.

Implementability: Wet screening and classification can be readily implemented using common soil treatment and handling technologies. This alternative can meet the current needs of the Site development plans and no soil above the CLs would remain on the Site. The implementation of this alternative on soil impacted by arsenic would be considered innovative and the implementation would

require significant effort during the start-up period. Handling of chelants could require special precautions.

Cost: A direct cost range of $75.3M to $120M is estimated for implementation of this alternative. The -200 mesh soil and precipitated concentrates (10% of whole soil) will be disposed of off-Site as a hazardous waste.

Considerations: This alternative may be effective in treating lead soil, but is has questionable effectiveness and implementability for arsenic only soil. It is also a time consuming and expensive process that could also be ineffective short-term due to chelant handling on the Site. As such, it will not be retained for further analysis.

Adjustments to remediation levels: No adjustments to the remediation levels used in the RA are warranted for this alternative.

6.6 Ranking of Alternatives

Ranking of the alternatives, described and discussed in Section 6.4, was conducted using the criteria defined in Section 6.2. The project team independently ranked the alternatives and the results were compiled into a single ranking for each alternative (Appendix E). This allowed the semi-quantitative ranking of the best and least favorable alternative for the particular criterion.

Different weightings were applied to the criteria to examine the sensitivity of the ranking results as the weightings were varied. For lead- and arsenic-impacted soils, the weighting factor had a small effect on the overall ranking of the alternatives. The alternatives were close in each case and the highest ranked alternatives still ranked high following the application of different weightings.

6.7 Summary of Selected Alternatives

No Action and three remedial alternatives of the eleven described and evaluated in this chapter were retained for further detailed analysis in Chapter 7. The alternatives retained for detailed analysis were:

- No Action;
- Off-Site Disposal at a Landfill;
- On Site Deposition, Cap and Cover; and
- Wet Screening with On-Site Deposition, Cap and Cover and Disposal of the Residual Soils at a Landfill

Four additional alternatives were retained for small scale or “spot” applications. These were:

- Cap;
- Cover;
- Cap/Cover; and
- Off-Site Disposal at a Landfill.

The selection of each of the alternatives was based on the ability of the alternative to provide a higher level of effectiveness, implementability, and/or lower cost than other alternatives that use similar technologies. This results in the best alternatives for each technology being retained for the detailed analysis. Two of the alternatives (No Action and Off-Site Disposal at a Landfill) were retained for cost comparison.

A summary of why each of the alternatives was retained is presented below.

6.8 Retained Alternatives: Large Scale Applications

No Action: Even though it does not meet cleanup standards by either the criteria listed in WAC 173-340-700 or WAC 173-340-7490(6)(f), the No Action alternative was retained for comparative purposes. It represents the low cost alternative.

Off-Site Disposal at a Landfill: This alternative meets cleanup standards and is permanent (for the Site). It was, therefore, retained for further evaluation. This alternative also represents the highest reasonable cost, which would be incurred by a cleanup action. This alternative represents the high cost option.

On Site Deposition, Cap and Cover: This alternative meets cleanup standards, meets RAOs, minimizes risks, is easily implemented, and represents reasonable costs. It is the most protective of the containment (cap or cover) alternatives and was, therefore, retained for further evaluation.

Wet Screening with On-Site Deposition, Cap and Cover and Disposal of the Residual Soils at a Landfill: This alternative represents the most practical of the volume reduction alternatives. It is effective (meets cleanup standards), is easily implemented, has been proven to be successful (2001 Screening Program), has the lowest overall cost and represents the lowest short-term risk of this group of technologies. For these reasons this alternative was retained for further evaluation.

6.9 Retained Alternatives: Small Scale Applications

Even though large-scale applications of the following technologies may be either ineffective (do not meet RAOs) or are overly expensive for the benefit they offer, they may be appropriate for Miscellaneous Small Units. They will be evaluated further in Section 8.3.

- **No Action:** No Action may be appropriate in locations where special considerations apply. These areas could include those areas of environmental sensitivity, special cultural significance or locations of contaminants that meet certain criteria.

- **Cap:** Asphalt capping may be appropriate where trails, or parking lots are planned. Limited use of this technology would meet cleanup standards, be protective long-term (with active maintenance) and is cost effective.

- **Cover:** A thick soil cover may be appropriate where disturbance of in-situ soils could cause significant harm to areas of environmental sensitivity, or special cultural significance.

- **Cap/Cover:** The application of a cap/cover (as described in Section 7.2.3) may be appropriate where an exposure barrier is desired. This technology is as appropriate for in-situ soils as it is for areas of soil deposition especially in areas of special cultural significance.

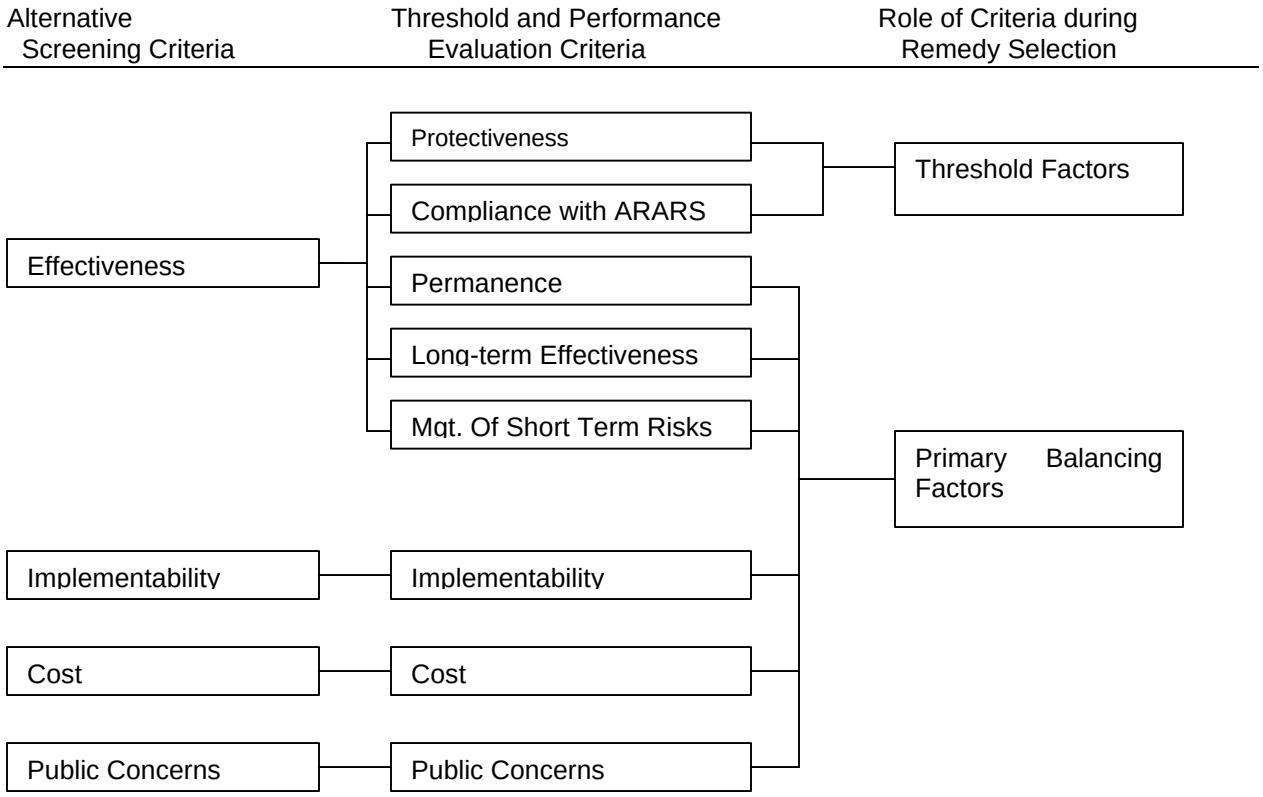
- **Off-Site Disposal at a Landfill:** Excavation and disposal of small volumes of contaminated soils could be appropriate. This technology has particular value in remediating “Miscellaneous Small RUs”.

TABLE 6-1 - ESTIMATED LOW AND HIGH RANGE UNIT COSTS

LOW RANGE UNIT COSTS ALTERNATIVE	APPROX. TOTAL COST ($)
No Action	$0
Cover	$43,200,000
Capping	$79,200,000
Cap/Cover	$21,600,000
On-site Deposition with Cap/Cover	$13,248,000
Off-site Disposal at Landfill	$181,296,000
Soil Washing with chelants and offsite disposal	$75,312,000
Soil Washing with acid and offsite disposal	$76,896,000
Wet Screening with Stabilization, On Site Deposition, Cap/Cover	$46,656,000
Wet Screening, Classification and Disposal at Landfill	$61,920,000
Wet Screening, On-site Deposition, Cap/Cover and Off-Site Disposal	$59,904,000

HIGH RANGE UNIT COSTS ALTERNATIVE	APPROX. TOTAL COST ($)
No Action	$0
Cover	$72,000,000
Capping	$129,600,000
Cap/Cover	$41,472,000
On-site Deposition with Cap/Cover	$21,600,000
Off-site Disposal at Landfill	$248,832,000
Soil Washing with chelants and offsite disposal	$120,096,000
Soil Washing with acid and offsite disposal	$120,096,000
Wet Screening with Stabilization, On Site Deposition, Cap/Cover	$84,096,000
Wet Screening, Classification and Disposal at Landfill	$110,592,000
Wet Screening, On-site Deposition, Cap/Cover and Off-Site Disposal	$99,216,000

Figure 6-1 – Relationship of Screening Criteria to the Evaluation Criteria



Chapter 7 – DETAILED ANALYSIS OF ALTERNATIVES AND SELECTION OF PREFERRED ALTERNATIVES

7.1 Introduction

This chapter evaluates how each alternative, retained from the screening of alternatives in Chapter 6, would be applied to each RU at the Site and presents a comparative analysis of these alternatives. Some alternatives evaluated in Chapter 6 are not appropriate for smaller scale applications (less than 2 acres in size or 5,000 cubic yards in volume). As such, this section will be include both the evaluation of the preferred alternative for larger scale (ranging from greater than 2 acres in size to total Site remediation) and the alternatives that may be used for small scale applications less than 2 acres.

In addition to the No Action alternative, which is retained as a baseline, the three primary remedial alternatives (to be used on a large scale basis) considered in the detailed analysis are as follows:

- On-Site Deposition, Cap and Cover;
- Off-Site Disposal at a Landfill; and
- Wet Screening with On-Site Deposition, Cap and Cover and Disposal of the Residual Soils at a Landfill.

In addition to the No Action alternative, which may have limited applications, the four primary remedial alternatives (to be used on a small-scale basis) considered in the detailed analysis are as follows:

- Cap;
- Cover;
- Cap/Cover; and
- Off-Site Disposal at a Landfill.

The details of how each alternative is able to successfully treat soils from different RUs are crucial to evaluating the alternatives. Not all RUs can be treated by each alternative; an alternative may be selected as the preferred alternative based on its effectiveness in treating a particular RU. The applicability of the alternatives to each specific RU is discussed in Chapters 5 and 6.

Section 7.2 describes the alternatives being retained for detailed analysis and identifies the large-scale RUs and volumes of soil which these alternatives may treat. Section 7.3 is the comparative detailed analysis of these alternatives. It also describes the evaluation criteria and rates each alternative. Section 7.4 summarizes the analysis of the alternatives. Section 7.5 describes the preferred alternatives for large-scale RUs, and any adjustments that implementation of the alternative would have on Site-specific RLs.

Section 7.6 describes the alternatives being retained for detailed analysis and for use in small-scale applications and Miscellaneous Small RUs. Section 7.7 is the comparative detailed analysis of these alternatives. It also describes the evaluation criteria and rates each alternative. Section 7.8 summarizes the analysis of the alternatives. Section 7.9 describes the preferred alternatives.

The detailed analysis of alternatives presents comparative results on the performance of each alternative for each RU. The most consistently performing alternatives are described in detail in Chapter 8.

7.2 Description of the Alternatives Retained for Detailed Analysis – Large Scale Applications

The following descriptions of alternatives are presented as they would be implemented for the RUs described in Section 3.2. These descriptions define how the alternative achieves the RAOs.

7.2.1 No Action

This alternative is retained for the purpose of comparing the current Site condition to the result of implementing any of the other remedial alternatives. No Action does not meet cleanup standards and will not be used for large-scale applications.

7.2.2 Common Activities

Certain common activities will be required for remediation of Site soils when the remedial alternatives involve excavation of in-place soil. These common activities include excavation, stockpiling, characterization and verification sampling and analysis, and regulatory classification of stockpiled soils prior to off-Site disposal, treatment, or on-Site deposition.

Analytical Field Screening: Where necessary (e.g., debris areas), field-screening samples will be collected to guide the cleanup action and allow for more cost-effective excavation of the impacted soil.

Site Preparation: Clearing and grubbing would be done once approval to proceed is given by Ecology. During this task, all vegetation would be removed from the areas to be excavated. Vegetation would be chipped and deposited on-Site. The work areas will be inspected by trained archeologists to determine if cultural or archeological artifacts are present. If any artifacts are found they will be treated in the manner described in the Cultural Resource Protection Plan that will be part of the Cleanup Action Plan (CAP) for the Site.

Excavation: Soil above the RL will be excavated to a depth of one foot of soil in impacted areas as delineated by the RI or by additional sample data, except in specific areas where soils are impacted at depths greater than one foot.

Verification Sampling and Analysis: Verification soil samples (i.e., 5-point composites) will be collected from the excavated area and analyzed. Analytical results will be evaluated to determine compliance. If soil remaining in the excavation does not meet Site RLs or, if applicable, CLs, additional excavation and verification sampling and analysis will be performed.

Haul/Stockpile: Excavated soil will be transported directly to either a low exposure risk area (e.g., golf course areas) for deposition or transported to a central area and stockpiled in preparation for treatment or disposal.

7.2.3 On-Site Deposition, Cap and Cover

General Process: In general, this alternative would involve the mass excavation of the top one foot of soil in targeted areas of the project Site, followed by the transfer of the excavated soil, and the consolidation of these soils in selected locations on-Site. Additional excavation would be required for soil greater than one foot below current ground surface if either confirmational or RI testing showed that they contained contaminant concentrations greater than CLs. Each of these consolidation locations would be capped and lie beneath the planned golf course.

Excavation Methods: Excavation of soils greater than the Site-specific RLs for lead and arsenic would occur by the following methods. All excavation work done within the first three feet of the current ground surface will be monitored by trained archeologists to determine if cultural or archeological artifacts are present. If any artifacts are found they will be treated in the manner described in the Cultural Resource Protection Plan that will be part of the Cleanup Action Plan (CAP) for the Site.

Method 1) Scraping: The majority of the shallow soils (up to 1.0 foot deep) will be excavated using self-loading pan scrapers. This method would be used on those areas within Parcel 1 that are not historical or open space RUs. Some selected excavation could occur within the golf course areas. The general scraping process would be:

- Phase I – The upper six inches of soil would be removed, using a self-loading pan scraper.

- Phase II - The remaining six inches of soil would be graded into a windrow and picked up by the pan scraper. If gravel were encountered prior to reaching the target depth, further excavation would be terminated at the gravel layer. The gravel represents a natural barrier to penetration of the subsurface by burrowing organisms. GPS will be used confirm the initial depth, followed by a complete survey to confirm the depth excavated.

Method 2 – Selected Excavation:

- In those areas not accessible to the pan scrapers (because of topography or other reasons), an excavator will be used to selectively excavate the soil in six to eight inch lifts until the desired depth of one foot. The excavated soil will be loaded into off-road haul trucks and transported to the PAs for placement. Direct pushing of soils into the PA is also possible for areas adjacent to the PAs. GPS will be used to confirm the initial depth, followed by a complete survey to confirm the depth excavated.

All of the material excavated, by either method, will be placed in the placement/consolidation areas (PAs) within the golf course areas and rough-graded.

Cap Construction: A golf course would be constructed on the project Site as an engineered cover (cap) for contaminated soils and, if necessary, contaminated debris. The majority of this material would be imported from the commercial land use areas of Parcel 1 and consolidated in roughly 73 acres of the approximately 180-acre golf course footprint. These 73 acres would constitute the PAs. Only soils and debris that contain contaminant concentrations equal to or less than the golf course remediation levels would be placed in the PAs. Each PA would be capped with 18 inches of clean soil by one of the following two methods listed below. This cap would also be placed on any areas within the golf course with in-situ contaminant concentrations (if not excavated) less than the golf course remediation level but greater than the Site-specific commercial remediation level.

- **Method One:** Six inches of clean soil would be placed over 12 inches of pit run gravel. In this process, the gravel would act as an exposure barrier to ecological receptors. The six inches of clean soil would act as an additional exposure barrier to individuals most likely to be exposed—the golf course worker, who on occasion may find it necessary to install drainage ditches or repair irrigation pipe.
- **Method Two:** Eighteen inches of “pit run” soil would be placed over a geotextile. In this case, the 18 inches of soil would act as the human health exposure barrier and the geotextile will act as the ecological exposure barrier.

Application: This alternative is potentially applicable to the following RUs:

- Golf Course RUs, and

- Commercial RUs

The volume of impacted soil associated with these RUs is approximately 714,000 CY.

7.2.4 Off-Site Disposal at a Landfill

General Process: This alternative would involve the excavation of a minimum of one foot of soil in targeted areas of the project Site. Since the planned golf course would not be constructed under this option the acreage excavated and, thus, the volume would be larger than other retained alternatives. Additional excavation would be required for soil greater than one foot below current ground surface if either conformational or RI testing showed that they contained contaminant concentrations greater than CLs. The excavated soils would be stockpiled, sampled, and transported to an approved off-Site disposal facility.

Application: This alternative is potentially applicable to the following RUs:

- Golf Course RUs;
- Commercial RUs ; and

The volume of impacted soil associated with these RUs is approximately 1,190,500 CY.

7.2.5 Wet Screening with On-Site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill

General Process: This alternative would involve the excavation of a minimum of one foot of soil in targeted areas of the project Site. Additional excavation would be required for soil greater than one foot below current ground surface if either confirmational or RI testing showed that they contained contaminant concentrations greater than CLs. These soils would be stockpiled prior to wet screening. Wet screening, as described in Chapter 6, is an effective technology for reducing the total volume of soil needing treatment. Based on the treatability study conclusions and the results of the 2001 Screening Program, it is assumed that wet screening will concentrate the lead and arsenic in the soil into 10 percent of the original soil volume. The residual soils would be loaded into 30-ton haul trucks, transported to and disposed of at an approved landfill. The process soil that met Site-specific golf course remediation levels would be transported to the golf course PAs for on-Site deposition and contained under a cap/cover. Section 7.2.3 describes the cap construction methods.

Application: This alternative is potentially applicable to the following RUs:

- Golf Course RUs;
- Commercial RUs; and

The volume of impacted soil associated with these RUs following wet screening is approximately 714,000 CY.

7.3 Comparative Detailed Analysis of Alternatives – Large Scale Applications

The following analysis provides information for the selection of a preferred alternative for each RU. This detailed analysis of alternatives will be comparative. The advantages and disadvantages of each retained alternative are identified and compared against the other alternatives to determine their relative performance according to each criterion.

The threshold criteria—protection of human health and the environment and compliance with cleanup standards—are those criteria that must be met for the alternative to have been retained from the screening described in Chapter 6. Each retained alternative meets the threshold criteria for lead and arsenic soils, with the exception of No Action, which is retained for comparison with the current Site condition.

The comparative analysis describes the evaluation criteria and presents the most favorable alternative first and includes the remaining alternatives in decreasing order of ability to satisfy the criteria.

The criteria to be used for the comparative detailed analysis of alternatives include the following:

- Long-term effectiveness and permanence;
- Reduction of toxicity, mobility, and volume;
- Short-term effectiveness;
- Implementability;
- Cost; and
- Consideration of Public Concerns.

7.3.1 Long-Term Effectiveness and Permanence

Long-term effectiveness measures the effectiveness of the cleanup action after the cleanup standards have been met. The primary focus of this comparison is to weigh the controls that may be necessary to manage the treatment residuals or untreated soil. This is done in two ways: by assessing the magnitude of the residual risk; and by assessing the adequacy of the individual controls to manage the treatment residuals or untreated soil. This long-term effectiveness comparison does not consider the residual risk or controls that may be associated with the off-Site landfill alternatives. The evaluation of "certainty of success" was omitted from this evaluation since each of the cleanup alternatives being evaluated will need to attain cleanup standards before demobilization can occur. The cleanup of the Site will be performed over a period of time during which "success" can be measured with a high degree of certainty for each process.

Magnitude of Residual Risk on Site: Each remedial alternative will have low residual risk since each will leave only acceptable concentrations of constituents (below either cleanup or remediation levels) on Site. Some alternatives have less residual risk than others. Excavation of soil above the RL means that the Site meets the remediation levels, which are based on acceptable levels of risk. The following discussion relates to the relative magnitude of low residual risk from residual soils generated by each alternative.

- The least residual risk on Site will be associated with Off-Site Disposal at a Landfill. Implementation of this alternative will result in no soil above the CL remaining on the Site.
- Slightly more residual risk will be associated with the Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill and On-Site Deposition with Cap and Cover alternatives, which include off-Site disposal of soils exceeding the golf course RL. Risk is further reduced by minimizing the potential for direct contact exposure routes with the use of a Cap/Cover.
- The No Action alternative would not modify the current Site condition and residual risk would be similar to the current risk. Future land uses would be restricted and current access restrictions would be maintained.

Adequacy and Reliability of Controls: The adequacy and reliability of controls relate to future land uses at the Site. Long-term development plans would impact only the No Action alternatives.

- Off-Site Disposal at a Landfill will require the lowest degrees of long-term management. Environmental audits of appropriate off-Site landfill facilities have determined that current controls implemented at those facilities are acceptable.

- Both On-Site Deposition with Cap/Cover and Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill rely on the Cap/Cover to reduce the potential for exposure to humans and ecological receptors. The Site development plans support the long-term management of these soils if they are located under the golf course.

- No Action would require that general access to impacted areas be restricted. Application of various institutional controls may be required to prevent exposure.

7.3.2 Reduction of Toxicity, Mobility, and Volume

This evaluation criterion addresses Ecology's preference for selecting remedial alternatives that use treatment technologies that permanently and significantly reduce toxicity, mobility, and volume of the constituents in Site soils. This evaluation focuses on the ability of alternatives to reduce the total volume of impacted soils, and irreversibly reduce mobility and toxicity of the constituents.

Implementation of any of the alternatives, except No Action, will address the highest concentrations of constituents in the soil.

Total Volume Reduction: Reduction of the volume of impacted soils is compared in this evaluation. Because metals are present in Site soils, destruction/reduction of the elemental constituents is not an option; thus, only soil volume reduction is considered.

- Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill has the potential to reduce the total impacted soil volume by up to 90 percent. As such, it represents the alternative that results in the highest amount of volume reduction.

- Off-Site Disposal at Landfill, On-Site Deposition with Cap/Cover and No Action would not reduce the volume of impacted soil. Off-Site Disposal would result in the material being transported from the Site and placed in an engineered landfill.

Mobility Reduction. The reduction of mobility is based on the alternative's ability to permanently prevent constituents from transport along potential exposure pathways. Since stabilization and other technologies that reduce leachability do not meet cleanup standards, the pathway considered is direct contact. Alternatives that involve excavation of soil above the RLs would permanently reduce the potential for direct contact exposure in the excavation area by removing the source of constituents.

- Off-Site Disposal at a Landfill would result in all soil above CLs being transported to a controlled landfill, where the mobility of the constituents would have to be controlled with liner and cap containment for the long term.

- Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill would indirectly reduce the mobility of the constituents because this treatment results in a smaller portion of the impacted Site soils being available as a potential future source for migration. The coarse material returned to the Site would not be a significant source for direct contact exposure. This alternative also reduces the possibility of direct contact with contaminated soil by using a Cap/Cover.

- The On-Site Deposition with Cap/Cover alternative also reduces the possibility of direct contact with contaminated soil by using a Cap/Cover. Developing and following health and safety procedures could limit exposure to workers during future subsurface construction or maintenance at deposition locations.

- No Action would not reduce the mobility of the constituents at the Site.

Toxicity Reduction: This evaluation is based on the ability of the alternative to destroy or convert the Site constituents to a less toxic form. Lead and arsenic in Site soils are elemental, and their destruction is not practical. None of the retained alternatives are intended to reduce the toxicity of lead or arsenic in soil.

7.3.3 Short-Term Effectiveness

This evaluation criterion addresses the effects of the alternative during the construction and implementation phases of the cleanup action. Each alternative is evaluated with respect to the potential impact on human health of the surrounding community, site workers, and the environment.

Potential Community Exposure during Implementation: This aspect of short-term effectiveness addresses any risk that results from implementation of the proposed alternative, such as dust generation during materials handling and transportation, and air emissions resulting from equipment operation. Dust generation would require monitoring so that the level of dust generated during soil handling does not exceed allowable levels in downwind areas. Dust control methods (i.e. applying water to work areas prior to and during excavation) would be required. The air quality impacts would be monitored to protect both Site workers' health and safety. In addition, work done within 500 feet of the southern boundary of the Site would require perimeter dust monitoring and dust prevention measures. Transportation of soils off-Site may have a very low potential for exposure. As a result the quantity of material being treated on-Site and/or transported to an off-Site landfill is the basis for this evaluation.

- No Action has the lowest risk associated with implementation since no soil is treated or removed from the Site.

- On-Site Deposition with Cap/Cover will require management of dust generation associated with the blending and amendment of soil or excavation and deposition. Only a small volume of soil would be transported off-site with this alternative.

- Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill, since it would be concentrating contaminants, would generate a greater volume of soil that requires off-site disposal than On-Site Deposition with Cap/Cover. It also requires a greater degree of soil handling since not only is the same volume of soil excavated, as On-Site Deposition, but it is also screened. This alternative will require management of dust generation associated with the excavation and handling of the soil, and during any subsequent deposition of treated soils on the Site.

- Off-Site Disposal at a Landfill will require the most controls to minimize risk associated with dust generation. Dust generation associated with the excavation of the soil and transportation will require management because all soils above CLs will be transported to an appropriate landfill.

Potential Worker Exposure during Implementation: This factor assesses potential threats that may be posed to the workers and the effectiveness and reliability of protective measures that would be taken during implementation of the cleanup action.

Personal protective equipment (PPE) appropriate for the type of potential exposure would be worn to reduce worker exposure. Workers would be trained in the health and safety procedures appropriate for their respective tasks, and operation of equipment (trucks, backhoes, and other heavy equipment) and would comply with the appropriate safety regulations.

Several alternatives would generate dust and/or require transportation to a landfill during implementation. Dust generation will be managed by wetting the soil during handling, paving the centralized treatment area, and/or covering stockpiles when not adding or removing material. Transportation of soil to the landfill will be managed by conforming to applicable Department of Transportation regulations.

The total volume of material handled and the use of water or extraction solutions are the leading criteria for this evaluation.

- Since no excavation, transport or processing of contaminated soils occur, No Action has the lowest potential for worker exposure.

- On-Site Deposition with Cap/Cover requires management of dust generated during the excavation, transport and on-Site placement of soils, and the construction of the Cap/Cover.

- Off-Site Disposal at a Landfill requires management of dust generated during the excavation, transportation and off-Site disposal of the soils.

- Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill will require management of dust generated during excavation, processing, transport and on-Site placement of soils, construction of the Cap/Cover, and transportation and off-Site disposal of the soils. In addition, workers will require additional PPE to prevent injury from the moving parts of the screening plant.

Potential Environmental Impacts: This factor addresses the potential adverse environmental impacts that may result from the implementation of the alternative and evaluates the mitigation measures which could be implemented to prevent or reduce these impacts. Potential environmental impacts include but are not limited to: dispersion of constituents; treatment water releases; spills; and wildlife exposure. All alternatives (except No Action) are believed to have the same impacts during the initial excavation of soils.

- Since no remedy would be implemented No Action has the lowest potential for adverse impacts on the environment during the implementation. It does, however, represent the alternative with the highest residual risk since no cleanup would have taken place.

- Off-Site Disposal at Landfill will have the lowest potential for adverse impacts on the environment during the implementation.

- On-Site Deposition with Cap/Cover will have a low potential for environmental impacts. The lead and arsenic constituents contained in soils amenable to cleanup action by these methods do not readily leach. If soil spills occur from the loading of trucks, they will be re-excavated. The underlying soils will be sampled to ensure the completeness of the cleanup.

- Since the screening plant would be placed upon a containment pad designed for the containment of soil and water spills, the Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill alternative will have a low potential for adverse impacts. It will have greater potential for impacts (vs. the above alternatives) due to increased handling of the soil. Process water is expected to contain only low to negligible metal concentrations, so the impact of a release of process water, if it occurred, would be low.

Time to Achieve RAOs: This factor estimates the time required to achieve the RAOs for the Site. The reduction of the constituent concentrations in the Site soil or the exposure risk to meet RAOs will be achieved by each alternative except the No Action alternative. The alternatives could be implemented in a timeframe that is principally limited by the time to complete excavation, verification sampling and analysis and, for the Off Site Disposal at a Landfill alternative, the time required to load and transport the contaminated soil off site. For the purposes of the cost evaluation the following was assumed:

- No Action would be completed immediately.

- On-Site Deposition with Cap/Cover was the fastest active alternative with a duration of 2.8 years.

- Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill alternative would require approximately 3.6 years to complete. This duration is based on a processing rate of about 1,250 tons per day, a six-month mobilization and start-up period, and a six-month demobilization and cleanup period.

- Off-Site Disposal at a Landfill will have the longest duration, 7.6 years, since the number of available trucks and the maximum truckloads per day limit the process. Table 7-1 lists the timeframes of each retained alternative.

7.3.4 Implementability

The Implementability criterion addresses the technical feasibility of implementing the alternative and the availability of materials and services. This evaluation will focus on the following criteria: ability and reliability of the technology to operate as would be required by the design and implementation schedule; ease of undertaking additional cleanup actions; and availability of services and materials. Additional criteria, such as availability of equipment, availability of commercially demonstrated technologies, administrative and regulatory requirements, scheduling, availability of appropriately sized equipment, construction access, and monitoring access, are considered to have minor impacts on the retained alternatives being evaluated in this section.

Ability and Reliability of Technology: This evaluation relates to the technical difficulties and unknowns associated with the alternative. Technical problems associated with the implementation of the alternative may prevent attainment of the remediation or cleanup levels or result in delays in the cleanup schedule.

- No technical difficulties or problems would be associated with the No Action alternative.

- On-Site Deposition with Cap/Cover would be readily implementable.

- Off-Site Disposal at a Landfill would be readily implementable. Capacity of the landfill is not a limiting factor and only small transportation problems are anticipated. No delays in the excavation and disposal process are anticipated.

- Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill could be readily implemented. Wet screening technologies have been proven on large scales at several sites and have been successfully used on the Site. Only minor delays associated with the startup of a process containing a number of mechanical operations are anticipated.

Ease of Undertaking Additional Actions: This evaluation discusses what, if any, future cleanup actions may be necessary and how difficult it would be to implement such additional actions after soil treatment by one or more of the alternatives.

- No Action would not modify existing Site conditions so that additional actions would be easy to implement.

- Off-Site disposal would be considered a permanent solution. Further cleanup actions would not be anticipated following the implementation of these permanent disposal and/or treatment alternatives.

- Any additional actions associated with the On-Site Deposition with Cap/Cover and Wet Screening with On-site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill would be associated with the placement areas. As long as permanent structures, such as buildings, are not constructed on top of PAs in the golf course land use area, subsequent action, if required, could be readily implemented in these areas.

Availability of Services and Materials: This evaluation considers the availability of the materials and equipment to implement the alternative, as well as the availability of contractors to provide competitive

bids. Cleanup actions directed toward soil impacted with lead and arsenic have been and are currently being implemented throughout the Northwest, North America, and Europe. Many vendors were questioned regarding the technology they use, and the information they provided was used in the screening of alternatives. These same vendors continue to provide updates on their activities and new developments in the technologies as a result of field demonstrations of soil treatment. The screening of alternatives also identified remedial technologies that are not complex to operate and use common construction processes and equipment. Based on these considerations, the availability of services and the necessary materials to achieve the RAOs are not anticipated to be a limiting factor and are unlikely to impact schedule for any of the remedial alternatives.

7.3.5 Cost

This evaluation includes an assessment of costs that may be incurred during the cleanup action. The evaluation considers three cost categories: direct cost; indirect cost; and long-term operation and maintenance (O&M) cost and present the sum for each alternative.

Direct Capital Costs: Direct capital costs are considered to be those costs associated with the implementation of the remedial alternative for impacted soil at the Site. These costs are associated with construction, equipment, Site preparation, operation/maintenance, and disposal. Direct costs were obtained from several sources, including vendor solicitations, previous experience, and actual costs for disposal of soil generated during interim source removal at the Site. The ranges of direct costs compiled from these sources are presented in Tables 7-2.

Indirect Capital Costs: Indirect capital costs are those costs associated with administration, community relations, engineering design, construction oversight, and contingency for the alternative. These costs were estimated based on previous experience during interim source removal. Detailed tables of the cost estimates are provided in Appendix F. Tables 7-3 presents a summary of estimated indirect remediation costs.

Total Costs: Table 7-4 presents a summary of the total costs estimated for each alternative. They are:

- No Action represents the "no cost" option.
- On-Site Deposition with Cap/Cover represents the second lowest cost, ranging between $ 13.2 MM and $ 21.6MM.
- Based upon the costs associated with the 2001 Screening program costs for Wet Screening with On-Site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill would range between $46.6MM and $ 79.6MM. The average of this range is approximately 4.6 times higher than the average cost for On-Site Deposition with Cap/Cover.
- Off-Site Disposal at a Landfill represents the high cost estimate ranging between $ 181.3MM and $ 248.8MM. The average of this range is approximately 12.6 times higher than the average cost of On-Site Deposition with Cap/Cover and approximately 2.7 times higher than the average cost of Wet Screening with On-Site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill

Accuracy of Estimate: The estimates used on Tables 7-2 through 7-4 present the range of estimated total costs. These estimates of remedial action cost are assumed to be accurate to within -30 percent and +30 percent of the estimate where both estimates could vary by –30 to +30 percent of the listed value. In effect, the estimated "Best Estimate" remedial action cost would be defined as average of the high and low estimate. Additionally, cost estimates, which overlap by about 50 percent, should be considered equal for the purpose of this evaluation.

Note that the estimated total cost of Site remediation based on the preferred alternatives and the cost of completed ISR work at the Site is presented in Chapter 8.

7.3.6 Consideration of Public Concerns

MTCA calls for the evaluation of any local community concerns over the alternative and how the alternative addresses those concerns. Concerns over protection of cultural and historical sites and artifacts, long-term public health, and short-term public health have been addressed above. Concerns related to any additional short-term impacts, not covered above, are focused on the danger of truck traffic during off-Site disposal.

- On-Site Deposition with Cap/Cover represents the least public health and safety concerns since it represents the alternative with the least volume of soil leaving the Site and, with the installation of the Cap/Cover, minimizes the potential for exposure.

- Public concerns associated with Wet Screening with On-Site Deposition, Cap and Cover and Disposal of Residual Soil at a Landfill would be slightly higher than On-Site Deposition with Cap/Cover since more truck traffic would occur due to the greater volume of soil requiring off-Site disposal.

- Off-Site Disposal at a Landfill would require approximately 44,000 truckloads over 5.1 years and, thus, would cause great public concern.

- Public health and safety concerns should be highest under the No Action alternative since there would be no reduction in contaminant concentrations or potential for exposure.

7.4 Summary of the Detailed Analysis

Table 7-5 summarizes each alternative based on the results of comparative detailed analysis. For each evaluation criteria, each alternative was discussed in descending order of performance according to that criterion. Table 7-5 was prepared by giving the highest performing alternative a score of 1 and the weakest performing alternative a score of 5. In cases where it was not possible to distinguish performance given between alternatives, those alternatives were discussed together and given equal scores.

The subtotal scores for each evaluation criteria category (e.g. long-term effectiveness, Implementability, etc.) and the overall score for the sum of all criteria are presented in Table 7-5. Note that the lowest score indicates the best performance. The results obtained using this method are based on an equal weighting of each sub-criteria. This approach is consistent with MTCA guidance, which emphasizes the permanence of the selected remedial alternatives.

7.5 Preferred Alternative for Large Scale Applications

Based on the best overall score, On-Site Deposition with Cap/Cover is the preferred alternative followed by the Wet Screening alternative. Off-Site Disposal at a Landfill received the highest score making it the least attractive alternative. No action also received a good score because of its low cost but does not meet cleanup standards and, thus, cannot be used except in special circumstances (areas of ecological sensitivity).

This summary of the ranking of each alternative based on the comparative detailed analysis is further developed in Chapter 8, which describes the preferred alternatives in more detail.

7.6 Retained Alternatives: Small Scale Applications

7.6.1 No Action

No action may have some applicability to some land use areas that are highly ecologically sensitive and isolated occurrences of chemicals. The Sequalitchew Creek Canyon (excluding railroad tracks), and the open space setbacks surrounding Old Fort Lake, require special consideration to the impacts required to

cleanup existing contamination (largely low concentrations) vs. impacts to the local ecology if no action was taken. This net environmental benefit evaluation indicates that no action is a positive approach for these areas.

No action may also be appropriate for small isolated occurrences of chemicals that were not used or generated as part of the manufacturing activities or decommissioning of the buildings at the Site. For No Action to be an appropriate alternative the following conditions must be met:

- The contaminant must not have been detected in groundwater;
- Their concentrations are low (near the cleanup level);
- The average/mean concentration is below the cleanup level;
- The number of exceedances (less than 5%) of the cleanup level are low in comparison to the number of detections and/or samples collected; and
- No known sources for these contaminants are associated with activities at the Site.

7.6.2 Cap

General Process - Cap Construction: In general, this alternative would involve the construction of an impermeable cap over existing soils containing contaminant concentrations above the CL but below the RL for a particular area. An example would be the use of an asphalt cap. In this case, the asphalt and subbase would act as the human health exposure barrier and the geotextile will act as the ecological exposure barrier. No excavation of underlying soils would occur.

Applicable: This alternative is potentially applicable to the following RUs:

- Open Space RUs; and
- Commercial RUs.

7.6.3 Cover

General Process - Cover Construction: In general, this alternative would involve the construction of a thick (> 3 feet) soil cover over existing soils containing contaminant concentrations above the CL but below the RL for a particular area. A key component of this alternative is the required thickness of the cover necessary to create an effective barrier to human and ecological exposure. No excavation of underlying soils would occur.

Applicable: This alternative is potentially applicable to the following RUs:

- Historical Areas;
- Golf Course RUs; and
- Open Space RUs.

7.6.4 Cap/Cover

General Process – Cap/Cover: This alternative involves the same cap/cover process described in Section 7.3 above but on a smaller scale. No excavation of underlying soils would occur.

In general this includes the construction of an engineered cap/cover 18 inches in thickness using one of the two methods listed below. This cap would be placed on any golf course land use areas with in-situ contaminant concentrations less than the golf course remediation level but greater than the Site-specific commercial remediation level.

Method One: Twelve inches of clean soil would be placed over six inches of gravel. In this process, the gravel would act as an exposure barrier to ecological receptors. The 12 inches of clean soil would act as an additional exposure barrier to humans.

Method Two: Eighteen inches of "pit run" soil would be placed over a geotextile. In this case, the 18 inches of soil would act as the human health exposure barrier and the geotextile will act as the ecological exposure barrier.

Applicable: This alternative is potentially applicable to the following RUs:

- Historical Areas;
- Golf Course RUs; and
- Open Space RUs.

7.6.5 Off-Site Disposal at a Landfill

General Process – Cap/Cover: This alternative involves the same process described in Section 7.3 above but on a smaller scale. Soils above Site-specific CLs for non-lead and arsenic contaminated soils would be excavated, loaded into 30-ton trucks and hauled to and disposed of at an off-Site landfill.

Applicable: This alternative is potentially applicable to the following RUs:

- Miscellaneous Small RUs;
- Historical Areas;
- Golf Course RUs; and
- Open Space RUs.

7.7 Comparative Detailed Analysis of Alternatives – Small Scale Applications

The following analysis uses the same criteria as listed in Section 7.2 above and provides information for the selection of a preferred alternative for each grouping of Miscellaneous Small Remediation Units.

The threshold criteria—protection of human health and the environment and compliance with cleanup standards—remain the same as those for large scale applications. Each retained alternative meets the threshold criteria for lead and arsenic, with the exception of No Action, which is retained for special considerations only.

The criteria to be used for the comparative detailed analysis of alternatives, as described in section 7.3 above, include the following:

- Long-term effectiveness and permanence;
- Reduction of toxicity, mobility, and volume;
- Short-term effectiveness;

- Implementability; and
- Considerations on Public Concerns.

7.7.1 Long-Term Effectiveness and Permanence

Magnitude of Residual Risk on-Site: Each remedial alternative will have low residual risk since each will leave only acceptable concentrations of constituents (below the RL) on-Site. Some alternatives have less residual risk than others. Excavation of soil above the RL means that the Site meets the remediation levels, which are based on acceptable levels of risk. The following discussion relates to the relative magnitude of low residual risk from treated soil residuals generated by each alternative.

- The least residual risk on-Site will be associated with Off-Site Disposal at a Landfill. Implementation of this alternative will result in no known soil above chemical-specific CLs.
- Since they will meet clean up standards residual risk will be associated with the Cap, Cover or Cap/Cover alternatives be within limits acceptable to Ecology. Of these three alternatives, the least amount of residual risk is associated with the Cap and Cap/Cover alternatives. The effectiveness in reducing residual risk for the Cover alternative is associated with the thickness of the cover. A thick cover (>3 feet) represents the same degree of residual risk as the other two alternatives.
- The No Action alternative would not modify the current Site condition and residual risk would be similar to the current risk.

Adequacy and Reliability of Controls: The adequacy and reliability of controls relate to future land uses at the Site. Long-term development plans could impact three of the alternatives: Cap, Cover and Cap/Cover.

- The Off-Site Disposal at a Landfill alternative will require the lowest degrees of long-term management.
- The Site development plans support the long-term management of the Cap, Cover and/or Cap/Cover alternatives.
- No Action would require that general access to some impacted areas be restricted. Application of various institutional controls may be required to prevent exposure.

7.7.2 Reduction of Toxicity, Mobility, and Volume

Volume Reduction: Because metals are present in Site soils, destruction/reduction of the elemental constituents is not an option. Thus, only soil volume reduction can occur. None of the retained alternatives reduces the volume of impacted soils; off-Site Disposal at a Landfill transfers the volume of impacted soil to the landfill.

Mobility Reduction: The pathway considered is direct contact. Alternatives, which involve excavation of soil above the RL, would permanently reduce the potential for direct contact exposure in the excavation area by removing the source of contamination.

- Off-Site Disposal at a Landfill would result in all soil above CLs being transported to a controlled landfill, where the mobility of the contaminants would have to be controlled by containment in the long-term.
- Capping, Cover and Cap/Cover result in constituents being placed in a controlled land use area. The potential for constituents in the soil to become available for direct contact is reduced by these

controls. Developing and following health and safety procedures could limit exposure to workers during future subsurface construction or maintenance at deposition locations.

- No Action would not reduce the mobility of the contaminants at the Site.

Toxicity Reduction: No alternatives are intended to reduce the toxicity of lead or arsenic in soil.

7.7.3 Short-Term Effectiveness

This evaluation criterion addresses the effects of the alternative during the construction and implementation phases of the cleanup action. Each alternative is evaluated with respect to the potential impact on human health of the surrounding community, Site workers, and the environment.

Potential Community Exposure during Implementation: Dust generation would be the primary concern during implementation and would need to be monitored so that the level of dust generated during soil handling does not exceed allowable levels in downwind areas. Dust control methods (i.e. applying water to work areas prior to and during excavation) would be required. Work done within 500 feet of the southern and eastern boundaries of the Site would require perimeter dust monitoring and dust prevention measures. The air quality impacts would be monitored to protect Site workers' health and safety. Transportation of soils off-Site may have a very low potential for exposure. As a result the quantity of material being excavated on-Site and/or transported to an off-Site landfill is the basis for this evaluation.

- No Action has the lowest risk associated with implementation since no soil is treated or removed from the Site.

- Cap, Cover and Cap/Cover will require management of dust generated during any excavation of soils and with the construction of the cap, cover or cap/cover. Since no contaminated materials will be used to construct these features no additional exposure risk is represented by one alternative vs. another. No off-Site transportation of soil would occur with these alternatives.

- Off-Site Disposal at a Landfill will require the most controls to minimize risk associated with dust generation. Dust generation associated with the excavation of the soil and transportation will require management because all soils above CLs will be transported to an appropriate landfill.

Potential Worker Exposure during Implementation: Personal protective equipment (PPE) appropriate for the type of potential exposure would be worn to reduce worker exposure. Workers would be trained in the health and safety procedures appropriate for their respective tasks, and operation of equipment (trucks, backhoes, and other heavy equipment) and would comply with the appropriate safety regulations.

The total volume of material handled and the use of water or extraction solutions are the leading criteria for this evaluation.

- No Action has the lowest worker exposure associated with implementation.

- Cap, Cover and Cap/Cover require management of dust generated during any excavation of soils and the construction of the cap and/or cover. Since no contaminated materials will be used to construct these features no additional exposure risk is represented by one alternative vs. another.

- Off-Site Disposal at a Landfill requires management of dust generated during the excavation of the contaminated soil, and management of transportation because all soils above the CL would be transported to the appropriate landfill.

Potential Environmental Impacts: All alternatives (except No Action) are believed to have the same impacts during the initial excavation of soils.

- No Action and Off-Site Disposal at Landfill will have the lowest potential for adverse impacts on the environment during the implementation.

- Cap, Cover and Cap/Cover will have a low potential for environmental impacts. The lead and arsenic constituents contained by these alternatives do not readily leach into the environment and represent very low potential for environmental impact. The Cap alternative, using an impermeable material, would further lower the already low potential by preventing water infiltration through the impacted soils.

Time to Achieve RAOs: Due to the small volumes associated with the remaining alternatives there is no difference in time to meet RAOs, with the exception of No Action which will require no time but does not meet RAOs.

7.7.4 Implementability

Due to the small-scale nature of this evaluation factors that impact implementability are, generally, comparable.

Ability and Reliability of Technology: No Action would not pose technical difficulties or problems. All remaining alternatives would be readily implementable.

Availability of Services and Materials: The availability of services and the necessary materials to achieve the RAOs are not anticipated to be a limiting factor and are unlikely to impact schedule for any of the remedial alternatives.

7.7.5 Cost

Cost will not be used as a evaluation criteria for small-scale applications. This decision was made for the following reasons:

- Costs associated with small-scale applications vary little between alternatives; and

- The majority of the applications that would use these alternatives have either special considerations (historic or ecological sensitively) or will only be defined (volume, time, etc.) once remediation occurs (Miscellaneous Small RUs).

7.7.6 Consideration of Public Concerns

Due to the small-scale of these applications there is little difference between alternatives. An exception occurs in areas of the Site that have great public interest (such as Sequalitchew Creek Canyon). As such, a detailed description of the processes that will be used to address these “special concerns” will be presented in Section 8.1.

7.8 Summary of the Detailed Analysis – Small Scale Applications

Due to the small volumes associated with small scale applications an analysis involving weighting of criteria was not done. Selection of the preferred alternative was weighted toward permanence, net environmental benefit and impact to historical sites.

7.9 Preferred Alternative for Small Scale Applications

Since cost was not considered in this evaluation, Cap/Cover and Off-Site Disposal are the preferred alternatives for small-scale applications. Capping could have limited applications. No action is applicable in areas of ecological sensitivity and for small isolated occurrences of chemicals that were not used or generated as part of the manufacturing activities or decommissioning of the buildings at the Site.

This summary of the ranking of each alternative based on the comparative detailed analysis is further developed in Section 8.1 and Section 8.3, which evaluates the preferred alternatives against Small RUs and the Miscellaneous Small Units, respectively.

7.10 Comparative Detailed Analysis of Alternatives – Groundwater

The following analysis uses the same criteria as listed in Section 7.2 above and provides information for the selection of a preferred alternative for groundwater. This detailed analysis of the two alternatives (Natural Restoration and Active Groundwater Treatment) will be comparative; the advantages and disadvantages of each retained alternative are identified and compared against the other alternative to determine their relative performance according to each criterion.

7.10.1 Long-Term Effectiveness and Permanence

Magnitude of Residual Risk on-Site: Each remedial alternative will have low residual risk since each would be conducted until groundwater reaches drinking water standards. As such, there is no difference between the alternatives.

Adequacy and Reliability of Controls: Both Active Treatment and Natural Restoration would rely upon deed restrictions to restrict the use of groundwater to non-potable uses. As such, there is no difference between the alternatives.

7.10.2 Reduction of Toxicity, Mobility, and Volume

Volume Reduction: Secondary treatment associated with the Active Groundwater Treatment alternative would destroy/reduce a small quantity of DNT that may be recovered. It would not, however, destroy/reduce residual DNT concentrations below the drinking water standard; the target of the treatment process. Natural Restoration would not destroy/reduce DNT.

Mobility Reduction: The pathway considered is direct contact. Each remedial alternative would limit transport since each would be conducted until groundwater reaches drinking water standards. As such, there is no difference between the alternatives.

Toxicity Reduction: Secondary treatment associated with the Active Groundwater Treatment alternative would destroy a small amount DNT that could be captured as part of the process. Natural Restoration would not destroy DNT.

7.10.3 Short-Term Effectiveness

This evaluation criterion addresses the effects of the alternative during the construction and implementation phases of the cleanup action. Each alternative is evaluated with respect to the potential impact on human health of the surrounding community, Site workers, and the environment.

Potential Community Exposure during Implementation: This aspect of short-term effectiveness addresses any risk that results from implementation of the proposed alternative, such as direct contact with contaminated groundwater, exposure to treatment chemicals, if any, during transport and air emissions resulting from equipment operation.

- Natural Restoration has the lowest risk associated with implementation since no actions, other than monitoring, occur.

- Active Groundwater Treatment involves the pumping, processing and treating up to 7,000 gallons of groundwater per minute (gpm). The storage of water and transportation of any treatment chemicals would require management especially during off-site transport.

Potential Worker Exposure during Implementation: This factor assesses potential threats that may be posed to the workers and the effectiveness and reliability of protective measures that would be taken during implementation of the cleanup action.

- Natural Restoration has the lowest risk associated with implementation since no actions, other than monitoring, occur.

- Active Groundwater Treatment, due to the magnitude of the process, involves a significant increase in risk associated with mechanical and safety hazards. Chemical hazards associated with any treatment chemicals would require special care.

Potential Environmental Impacts: Potential environmental impacts include but are not limited to: dispersion of constituents; erosion control in case of a release of treated water; spills of treatment chemical, if any; and wildlife exposure.

- Natural Restoration has the lowest risk associated with implementation since no groundwater is stored and treated.

- Active Groundwater Treatment, due to the magnitude of the process, involves a significant increase in the potential risk of releases stored or treated water. Treatment ponds would have to be created causing an attractive nuisance to wildlife, chemical hazards could exist due to treatment chemicals.

Time to Achieve RAOs: The time to complete either alternative is unknown. Gradually declining terms in DNT concentrations indicate that groundwater will eventually be naturally restored. Active Treatment will require up to 20 years, or longer, (Appendix I) to reach RAOs. Pump and treat systems poor historical performance in achieving drinking water standards could indicate that RAOs may never be reached.

7.10.4 Implementability

The Implementability criterion addresses the technical feasibility of implementing the alternative and the availability of materials and services.

- Natural Restoration requires no implementation.
- Active Groundwater Treatment involves the construction, operations and maintenance of an extremely large treatment facility. Successfully implementing this alternative would be very difficult. The historical performance of groundwater pump and treat systems in restoring aquifers to drinking water standards has been poor suggesting that groundwater pump and treat to achieve drinking water standards everywhere in an aquifer may be technically infeasible (Appendix I).

Ability and Reliability of Technology: This evaluation relates to the technical difficulties and unknowns associated with the alternative.

- Natural Restoration is reliable and poses no technical difficulties.

- Pump and treat systems (Active Groundwater Treatment) have a poor historical performance in achieving drinking water standards. Concentrations in Site groundwater are already low enough that active groundwater pump and treat would likely be little or no more effective than natural restoration in removing the last residual DNT from Site aquifers

Availability of Services and Materials: Natural Restoration requires no services or materials. Pump and treat systems are readily available for small applications but not for the size required to treat the large volumes of groundwater at the Site. The treatment facility would have to be custom made. As such, materials would not be readily available.

7.10.5 Cost

Cost is a major factor in the determination of the preferred alternative of groundwater remediation.

- Natural Restoration involves the monitoring of groundwater until drinking water standards are met. The cost of this activity is roughly $ 9,000 per year.

- Active Groundwater Treatment will require between $33,000,000 and $58,000,000.

7.10.6 Consideration of Public Concerns

Since the goal of each alternative is groundwater concentrations below drinking water standards there is little difference between alternatives.

7.11 Summary of the Detailed Analysis

Analysis of the alternatives results in the following conclusions:

- Both Natural Restoration and Active Treatment will reach the same goal; drinking water standards; and thus, represent the same residual risk of exposure;

- Both Natural Restoration and Active Treatment will use deed restrictions to control future groundwater use;

- Active Groundwater Treatment could reduce/destroy a small amount of DNT;

- Active Groundwater Treatment represents a significantly greater risk for potential community, worker, and environmental exposure during implementation;

- Active Groundwater Treatment would be much more difficult to implement and may not be effective in reaching RAOs;

- Active Groundwater Treatment is much more costly; and

- Both Natural Restoration and Active Treatment address public concerns.

7.12 Preferred Alternative for Groundwater

The cost for Active Groundwater Treatment at the Former DuPont Works Site (Site) to meet the DNT drinking water screening level would be substantial and disproportionate to the degree of risk reduction which could be achieved. Therefore, in accordance with MTCA (WAC 173-340-360), it is impractical to consider active groundwater remediation at the Site for an end use (drinking water) that is not planned. Appendix I discusses the impracticability of this alternative. This conclusion is based on the following:

- Site groundwater poses no risk to human health or the environment.

    - Because off-Site drinking water supplies will supply more than double the full projected population of DuPont through the year 2020 , Site groundwater is not currently and will not in the future be used as a drinking water source (due to a deed restriction).

    - Future Site development plans will include deed restrictions as necessary to prevent drilling of drinking water supply wells;

    - Even assuming a hypothetical drinking water exposure that does not and will not exist at the Site, the highest DNT concentrations currently in Site aquifers (less than 0.5 µg/L) represent a worst-case risk of less than 4×10^{-6}, which meets a risk threshold of 10^{-5};

  - Current DNT concentrations pose no risk to golfers, other visitors, or golf course maintenance workers who would be most likely to encounter Site groundwater on a regular basis when it is used for golf course irrigation; and

  - Site groundwater poses no risk to any Site ecological environment (including Sequalitchew Creek and Old Fort Lake) or off-Site ecological environment (e.g. Puget Sound).

- Natural groundwater recovery will occur following the completed interim DNT source removal. Removal of more than 40,000 cubic yards of DNT-impacted Site soils has been completed, thus the source of DNT to Site groundwater has been removed;

- Already low DNT concentrations in Site groundwater may decline further because Site aquifers are highly permeable and DNT is mobile, allowing natural flushing of DNT from the groundwater system and further reductions over time in the already low risk under a hypothetical drinking water scenario; and

- The current Site groundwater monitoring program will continue to document the DNT concentrations over time,

- Acknowledging groundwater pump and treat systems poor historical performance in achieving drinking water standards, the existing DNT concentrations in Site groundwater would represent a reasonable remediation endpoint at sites where active remediation is under consideration or underway.

- The cost to implement active groundwater remediation would be excessive, with preliminary estimates ranging between 33 and 58 million dollars. Consistent with the intent of MTCA and CERCLA, resources should be directed toward making substantive reductions in overall Site risk, which will be best accomplished at this Site by addressing other contaminants remaining in soils.

Considering the above, Natural Restoration is the preferred alternatives for groundwater.

TABLE 7-1 - ESTIMATED TIMEFRAMES BY ALTERNATIVE
FORMER DUPONT WORKS SITE
DUPONT, WASHINGTON

Estimate of Time to Completion (Work days)	Pre/Post-Construction		CONSTRUCTION				
Alternative	Design	Permitting and Reporting	Work Days (WD)	Additional WD: Screening	Additional WD: Disposal	Total Work Days	Total Years
No Action	0	0	0	0	0	0	0

Chapter 8 – CONCEPTUAL DESIGN OF THE PREFERRED ALTERNATIVES

8.1 Introduction

The previous chapters of this FS report provide a description of the processes, which have been used to select appropriate remedial alternatives. Chapter 2 defines the objectives of the cleanup action (RAOs). Chapter 3 identifies the soil volumes, which require treatment. Chapter 4 identifies applicable technologies and process options, which can effectively treat the soils to meet the RAOs. Chapter 5 presents the findings of treatability studies performed on Site soil to better define the applicability of various technologies. Chapters 6 and 7 evaluate and compare alternatives and select a preferred alternative that can be used to cleanup the Site.

This section describes how the Site cleanup can be achieved using the preferred alternatives. Section 8.2 describes how the preferred alternative will be used in each RU to achieve cleanup goals. Section 8.3 describes the alternative to be used for Miscellaneous Small RUs. Section 8.4 summarizes an estimate of the total remediation cost for the entire Site.

8.2 Conceptual Design by Remediation Unit (Large Scale Applications)

This section describes the preferred alternatives and how they may be applied to each remediation unit.

Golf Course RUs: Golf Course RUs are defined by the property inside the golf course footprint, other than Miscellaneous Small Units. They consist of the following four sub-units:

- Golf Course Placement/Deposition Areas (PA): These are discrete areas within the golf course footprint that will be used to deposit soils from other RUs. Each PA will be capped with the Cap/Cover described in Section 7.2.3. No excavation is planned in these areas unless soils occur that that have arsenic or lead concentrations above the golf course remediation levels (i.e., 530 mg/kg for arsenic and 4,100 mg/kg for lead). These soils will be treated as “Hot Spots” as described in Section 8.3.
- Non-PA Areas within Golf Course RUs: This is the property within the Golf Course RUs that is not a PA. Soils in these areas will be excavated and placed within the PAs. Following the excavation of these soils, the resulting surface soils will be sampled (i.e., 5-point composite samples collected on a 75 foot grid) and if found to be above the golf course remediation level, re-excavated. In the unlikely event that confirmation sampling identifies soils that have arsenic or lead concentrations above the golf course remediation levels, they will be treated as “Hot Spots” as described in Section 8.3.
- Foundations within Golf Course RUs: Foundations of the former manufacturing building remain within the non-PA areas of the golf course. Elevated levels of lead contamination can occur in the vicinity of these foundations if the buildings were lined with lead sheeting or were either painted with or stored lead-based paint. The lead concentrations decrease significantly with increased distance from the foundation. As such, an excavation limit of 25 feet from the foundation wall will be used. No excavation will be done outside the 25-foot excavation limit. An excavator will be used to complete all the planned work. No bulldozers or scrapers will be used to excavate these soils. Excavated soils will be hauled by truck. All excavated soils will be placed in a PA **if their concentrations do not exceed golf course remediation levels**. In the unlikely event that confirmation sampling identifies soils that have arsenic or lead concentrations above the golf course remediation levels (i.e., 530 mg/kg for arsenic and 4,100 mg/kg for lead), these soils will be treated as “Hot Spots” as described in Section 8.3. Water will be used within the work area and on haul roads to control dust. All decisions on the need for further excavation will be based upon a “pass/fail” system in which if a sample exceeds screening concentrations the excavation will be deepened. No statistics will be used. Excavation and sampling will

continue until cleanup goals are met. Foundations that are located within placement areas will not be excavated.

- NGRR within Golf Course RUs: NGRR sections occur within the GC land use area. Past sampling determined that soils within 25 feet of NGRR centerlines can contain elevated arsenic concentrations. All soils within the 25 feet the NGRR centerline will be excavated to a depth of 1.5 feet. The sides of the rail bed will be excavated first, followed by the rail bed itself. The excavated soil will be hauled, by truck, to the nearest placement area and deposited unless, in the unlikely event that confirmation sampling identifies soils that have arsenic concentrations above the golf course remediation levels (i.e., 530 mg/kg for arsenic). These soils will be treated as "Hot Spots" as described in Section 8.3. Water will be used within the work area and on haul roads to control dust. All decisions on the need for further excavation will be based upon a "pass/fail" system in which if a sample exceeds screening concentrations the excavation will be deepened. No statistics will be used. Excavation and sampling will continue until cleanup goals are met. NGRR tracks that are located in PAs will not be excavated.

Open Space RUs: Open Space RUs consist of all Site property that will be left in its current condition. There are four open space RUs on-Site. Sequalitchew Creek NGRR has been excluded and will be considered a Miscellaneous Small Unit. They are Sequalitchew Creek Canyon (OS-01), open space north of Sequalitchew Creek (OS-02 NOC), open space south of Sequalitchew Creek (OS-3 SOC) and Old Fort Lake (OS-03).

The OS-1 RU is adjacent (i.e., south of) to Sequalitchew Creek. There are three locations where the lead concentrations exceed the ecological screening level and these three locations are classified as Miscellaneous Small Units (MSUs) and will be excavated.

There are several locations in OS-2 and OS-3 RUs where the arsenic or lead concentrations exceed the open space cleanup or remediation levels. These exceedances (including the former LR-68 hot spot which is the only location where remediation will occur on a side hill) are associated with former roads, hot spots, or are included in the Sequalitchew Creek NGRR MSUs.

The OS-4 RU is the open space surrounding Old Fort Lake. There are no lead exceedances, but there are four locations that have arsenic concentrations marginally above the area background concentration of 32 mg/kg.

No Action (other than MSU excavation) is proposed for Open Space RUs due to their special ecological sensitivity. The justification for this proposal is centered on the following five factors:

- Habitat: These RUs consist of vibrant ecological communities. Such habitat is important to the local ecosystem considering the amount of habitat that will be eliminated due to the remediation of all areas surrounding them.
- Low Contaminant Concentrations: Contaminant concentrations in these areas are low, with few locations where the Site-specific human health CLs are exceeded.
- Proximity to surface water: These RUs contain or are located within 100 feet of a surface water body. As such, excavation in these areas could cause significant impact, such as slope instability and potential sedimentation.
- Topography: These RUs have steep topological conditions. As such, containment of runoff from excavation activities could be problematic.
- Accessibility: Due to the steep topography, human exposure in these RUs will be limited to established travel routes.

Commercial RUs: Commercial RUs are defined by the property inside the Site that is planned for commercial land use applications, other than Miscellaneous Small Units. Soils in these RUs will be

excavated to a depth of 1.0 foot, and placed within the Golf Course land use PAs. Following the excavation of these soils, the resulting surface soils will be sampled, (i.e., 5-point composite samples collected on a 75 foot grid) and if found to be above the remediation level for the golf course land use, re-excavated. In the unlikely event that confirmation sampling identifies soils that have arsenic or lead concentrations above the golf course land use RLs, they will be treated as "Hot Spots" as described in Section 8.3.

Historical RUs: These RUs make up the areas of the Site that have historic significance, as defined by a listing with the Office of Archaeology and Historic Preservation. At this time three historical RUs are known to exist on-Site. They are:

- Fort Nisqually Cemetery: (45PI404)
- Shell Midden: (45PI72)
- 1833 Fort Nisqually Site (45PI55)
- Each of these areas are small in size (less than 2 acres) and could contain discrete locations where arsenic or lead concentrations above the Site-specific remediation levels (i.e., 60 mg/kg for arsenic and 118 mg/kg for lead) occur. As such, these RUs and/or the discrete areas they contain will be treated as either "small-scale applications" or "Hot Spots" as described in Section 8.3. Mass excavation will not be done in these RUs.

8.3 Conceptual Design (Small-Scale Applications and Miscellaneous Small RUs)

The selected remedy for each historical RU will be protective of human health and the environment and will be dependent on how the land is going to be used in the future. A different remedy may be selected for an area depending on who is going to use the land (e.g., children versus adults). Stakeholders' concerns regarding the cultural resources associated with each historical RU will also be a consideration in the remedy selection process. For example, based on cultural resource concerns, capping may be appropriate for one site (e.g., Fort Nisqually Cemetery) and inappropriate for another (e.g., Shell Midden).

The selection of the preferred alternative for these RUs was performed in Chapter 7. This section summarizes how each alternative will be applied to each remediation unit.

Historical RUs: Each of these areas are small in size (less than 2 acres) and could contain discrete locations where arsenic or lead concentrations above the Site-specific remediation levels (i.e., 60 mg/kg for arsenic and 118 mg/kg for lead). As such, these RUs and/or the discrete areas qualify as either a "small-scale application" or a "Hot Spot." They are:

- Fort Nisqually Cemetery (45PI404);
- Shell Midden (45PI72); and
- 1833 Fort Nisqually Site (45PI55).

RI and other characterization data show that discrete locations within the boundary of these RUs contain lead concentrations greater than CLs. These sites are of important historical significance and should be left undisturbed to the highest degree possible. To do this, no excavation will take place, and a Cap/Cover (as described in Section 7.6.5) will be installed over the contaminated soils to prevent direct contact. A deed restriction, prohibiting excavation in the areas covered by the Cap/Cover, will be necessary to ensure the long-term effectiveness of the Cap/Cover.

Golf Course Land Use RUs: No excavation will occur unless Site-specific RLs are exceeded. Soils with contaminant concentrations exceeding RLs are considered miscellaneous small remediation unit "Hot Spots" and will be remedied by the methods described in the following section.

Miscellaneous Small Remediation Units: Miscellaneous Small Remediation Units are defined as soils impacted by contaminants or contaminant mixtures that have an in-situ volume believed to be smaller than 5,000 CY. This volume was determined to be the limit below which extensive evaluation of remedial

alternatives or implementation of specialized on-Site treatment technologies would not be cost effective. Appendix G presents the procedures and assumptions used in defining the "small" remediation units.

- Similar mixture of contaminants: Soils above Site-specific CLs or RLs would be excavated, loaded, and hauled to an off-Site landfill for disposal, using 30-ton trucks.
- Similar deposition method: Soils above Site-specific CLs or RLs would be excavated, loaded, and hauled to an off-Site landfill for disposal, using 30-ton trucks.
- Small occurrence(s) of a single contaminant: The preferred alternatives for these MSUs is Excavation and Off-Site Disposal, where soils with selected contaminant concentrations above Site-specific CLs or RLs would be excavated, loaded, and hauled to an off-Site landfill for disposal, using 30-ton trucks, and No Action. No action would be appropriate for small occurrences of cadmium which has not been detected in groundwater, occurs in very low concentrations, has an average/mean concentration below the cleanup level, has a low number of exceedances (less than 5%) of the cleanup level in comparison to the number of detections and/or samples collected, and has no known source associated with activities at the Site.
- Contamination "hot spots" discovered during final cleanup: Soils above Site-specific CLs or RLs would be excavated, loaded, and hauled to an off-Site landfill for disposal, using 30-ton trucks.
- Debris: Debris with contaminant concentrations above Site-specific CLs or RLs would be excavated, loaded, and hauled to an off-Site landfill, using 30-ton trucks.
- Sequalitchew Creek NGRR: This RU is represented by the linear length of the track and the width of track bed from the toe of the uphill slope and the crest of the downhill slope. Soil with contaminant concentrations above Site-specific CLs or RLs would be excavated, loaded, and hauled to an off-Site landfill, using 30-ton trucks. The remainder of the track bed will be covered with a gravel subbase and capped with asphalt. This Cap will act as an exposure barrier to both human and ecological receptors.

8.4 Groundwater

Natural Restoration has been selected as the preferred alternative for the remediation of residual DNT in groundwater. Groundwater monitoring would be required on an annual basis until the monitoring wells reach compliance (represented by four consecutive sampling rounds showing DNT concentrations in the groundwater represented by that well are below the drinking water standard of 0.13 µg/L). Once this has been achieved the well will be closed by the proper methods (Chapter 18.104 RCW; Chapter 173-160 WAC) after approval from Ecology. Sampling of the remaining wells will continue until they reach compliance. Seep 1 will be sampled during the annual groundwater monitoring event after the surface soil mass excavation remediation work has been completed.

The highest DNT concentration in groundwater ever detected at the Site was 3.8 ug/L in MW-27 in January of 1995. If any of the results from future groundwater sampling is greater than 3.8 ug/L Weyerhaeuser and DuPont will meet with Ecology to discuss the results.

8.5 Estimate of Total Site Remediation Cost

The estimate of cost for the preferred alternative in this FS is based upon the application of the large-scale alternative (On-Site Deposition with Cap/Cover) for the majority of the Site and a combination of small-scale alternatives for small-scale and Miscellaneous Small RUs. The preferred alternative for each RU or small unit is summarized below:

Remediation Unit Type:	***Preferred Alternative***
Large Scale Applications	
Golf Course Land Use RUs	On-Site Deposition with Cap/Cover
Commercial RUs	On-Site Deposition with Cap/Cover
Open Space RUs	No Action

Small Scale Applications	
Historical RUs	Cap or Cap/Cover, On-Site Deposition with Cap/Cover
Golf Course Fill Areas	Cap or Cap/Cover
Small Miscellaneous RUs	
Similar mixture of contaminants	Off-Site Disposal at a Landfill
Similar deposition method:	Off-Site Disposal at a Landfill
Small occurrence(s) of a single contaminant	Off-Site Disposal at a Landfill, No Action
Contamination "hot spots" discovered during final cleanup	Off-Site Disposal at a Landfill
Debris (contaminated)	Off-Site Disposal at a Landfill
Sequalitchew Creek NGRR	Off-Site Disposal at a Landfill of "Hot Spots" and Cap (with asphalt) of NGRR track bed
Groundwater	
Site Wide	Natural Restoration

8.5.1 Cost for Remediation: Preferred Alternative – Large and Small Scale Applications

The costs for remediation of both large scale (the golf course land use RUs (excluding fill areas), commercial RUs and open space RUs) and small scale applications (Historical RUs, Golf Course Land Use fill areas and Miscellaneous Small RUs) are presented in Table 8 -1.

8.5.2 Cost of Groundwater Remediation

The cost for total Site remediation is approximately $ 9,000.00 per year. For this FS a 10-year period is estimated bringing the total to $ 90,000.00.

8.5.3 Cost for Total Site Remediation

The cost for total Site remediation, for the preferred alternatives, is presented in Table 8-2.

Table 8-1 – Summary of Remediation Costs: Preferred Alternative – Large and Small Scale Applications

Estimated Low and High Remediation Costs for Large Scale Applications

PREFERRED ALTERNATIVE:	LOW RANGE TOTAL COST	HIGH RANGE TOTAL COST	"BEST ESTIMATE" TOTAL COST
On-site Deposition with Cap/Cover	$13,248,000	$21,600,000	$17,424,000

Estimated Low and High Remediation Costs for Miscellaneous Small Remediation Units

RU TYPE	LOW RANGE TOTAL COST	HIGH RANGE TOTAL COST	"BEST ESTIMATE" TOTAL COST
Similar Mixtures	$ 63,370	$ 63,926	$ 68,833
Similar Deposition	$ 63,370	$ 63,926	$ 68,833
Single Contaminant	$ 63,370	$ 63,926	$ 68,833
"Hot Spots"	$ 636,965	$ 642,550	$ 691,876
Debris	$ 759,684	$ 766,344	$ 825,174
Sequalitchew Creek NGRR	$ 633,704	$ 639,259	$ 688,333
Total	$ 2,220,635	$ 2,240,103	$ 2,411,884

Table 8-2 – Summary of Site Remediation Costs

Item	"Best Estimate" of Cost
Proposed Remediation in FS [(1)]	$ 17,424,000
Miscellaneous Small RUs	$ 2,411,884
Groundwater[(2)]	$ 90,000
Total Cost of Site Remediation	$ 19,925,884

[(1)] Based upon preferred alternative listed in Section 8 and costs in Appendix F
[(2)] Based upon preferred alternative listed in Section 8 and costs listed in Appendix I

APPENDIX A – *DESCRIPTION OF REMEDIATION TECHNOLOGIES FOR SOIL*

A.1 Introduction

This appendix describes the remediation technologies and corresponding process options associated with each general response action listed in Section 4.3. The information in this appendix forms the basis for the screening of the technologies presented in Tables 4-1 and 4-2. The general response actions, technologies, and process options are organized in this appendix in the same order they are arranged on the tables.

The general response actions identified for the remediation of metals- impacted soils at the Former DuPont Works Site (Site) include:

- No Action;
- Institutional controls;
- Containment;
- Removal;
- Treatment; and
- Stabilization.

The technology performance is compared with the chemical concentrations observed at the Site and the remediation or cleanup level considered appropriate for the land use are presented on the figures. All the technologies are able to meet the RAOs.

A.2 No Action

The No Action alternative is retained throughout the feasibility study process. It provides a baseline to compare the other alternatives to evaluate their effectiveness. The no action response literally means leaving the Site exactly as it exists at the time of preparation of the FS.

A.3 Institutional Controls

Institutional Controls are physical or legal restrictions used to prevent exposure to Site constituents. Typically, exposure is prevented or reduced by restricting access to the Site or to potential constituent receptors—such as groundwater or wildlife. The toxicity, volume, and mobility of the constituents are not reduced.

For these restrictions to be effective, they require understanding and compliance by the population being protected. Two types of institutional controls (technologies)—access restrictions and monitoring—are described below.

A.3.1 Access Restriction

Access restriction falls into two basic types: physical restrictions and legal restrictions. The physical restrictions are usually easy to implement and very cost-effective. The legal restrictions are also easy to implement and restrict future use of the property.

Fence: Fencing a site is an inexpensive and effective method for restricting access. Simple fences (such as chain-link) accomplish significant reduction of potential human exposure. If required, special fences

can be constructed to keep out wildlife. Fencing does not prevent access to small burrowing animals or birds. Well-constructed fences may last many years with little maintenance. Since the Site will be developed as recreational, commercial, and industrial areas, fences will have little applicability. They are currently used to restrict access to the Site during the RI and interim source removal and will continue to be used during future cleanup actions.

Warning Signs: Warning signs are also very effective at restricting access at very little cost. They are most effective when used with fencing. Since the Site will be developed as recreational, commercial, and industrial areas, warning signs will have little applicability. They are currently used to restrict access to the Site during ongoing activities.

Deed Restrictions: Deed restrictions may be useful in preventing accidental exposure due to activities of future property owners. The deed restriction notifies future owners of specific Site conditions to prevent activities that may release constituents or increase exposure. Generally, Site-wide deed restrictions would reduce the value of the Site.

Fishing/Hunting Restrictions: These restrictions reduce human exposure by reducing the consumption of potentially impacted tissues. Since zoning prohibits hunting on the Site and no fish-bearing surface water body is present on the Site, this restriction is effectively in-place.

Health and Safety Equipment: Using appropriate health and safety equipment and supplies is essential for individuals working on the Site during the cleanup action and Site development. When used properly, equipment such as protective clothing, boots, and a respirator can prevent exposure.

A.3.2 Monitoring

Monitoring can be used to prevent exposure by detecting contaminant migration. Early detection of the contaminant allows corrective action to be taken prior to exposure. At this Site, monitoring may be relevant to the following media:

- Groundwater;
- Air (during cleanup action only); and
- Soil.

Air monitoring is particularly useful during remedial construction because of the greater risk of exposure from dust. Verification sampling of the soil can be used during construction to verify that the contamination has been addressed.

Groundwater and surface water monitoring is useful in situations where there is uncertainty as to how a constituent might migrate to and in the aquifer, or in the surface water.

Since groundwater or surface water has not been impacted by lead and arsenic during the operation of the facility there is little chance that groundwater will be impacted following cleanup action. Groundwater and surface water monitoring may be required in association with stabilization or related to existing DNT-impacted groundwater contamination.

A.4 Containment

Containment uses physical barriers to either prevent direct exposure to the constituent or prevent migration of the constituent into the environment. Migration may be prevented by either preventing movement of the impacted medium or preventing a transport agent—such as water—from contacting the impacted medium. Containment technologies do not change the nature of the constituent but reduce risk by preventing exposure to the constituent.

Four containment technologies for soil are discussed below; cover, cap, liner and cap/cover.

A.4.1 Cover

Covers are characterized by a physical barrier between the impacted medium and the atmosphere. Usually, the purpose of a cover is to prevent or reduce contact between the impacted medium and precipitation. Covers also serve to prevent exposure to wind and to prevent direct contact by humans or animals.

Covers are used when there is extensive subsurface contamination that is difficult to remove or remediate in-place. Covers are often used over stabilized material or residues from other treatment technologies. Covers may also be used over soil with constituent concentrations below remediation levels, but still above cleanup levels, to prevent direct contact and further reduce residual risk.

Clean Soil Cover: A clean soil cover consists of the placement of imported clean soil on top of the soil to be covered. It prevents direct contact with the covered soil and provides a good substrate for vegetation. As vegetation will prevent erosion, little maintenance of the soil cover may be required. It is an effective low cost option when no leachable constituents of concern are present.

Re-vegetation: Although it can be used alone, re-vegetation is usually associated with some form of soil cap. The vegetative cover protects the cap from wind and rain erosion. It can also prevent direct contact with uncapped impacted soil during the cleanup action process and reduce windblown dust. Re-vegetation does not, however, prevent direct contact to plants or burrowing animals.

A.4.2 Cap

Engineered Cap (Synthetic Membrane, Clay, Asphalt, Asphalt Concrete, Portland Cement Concrete, Multimedia): Low permeability caps can be constructed from a variety of materials, or combinations of several materials. Materials that may be used in cap design, either individually or in combination, include synthetic polymer membranes, clay, asphalt, asphalt concrete, or Portland cement concrete. These materials are subject to damage so that engineered caps require long-term maintenance. Engineered caps are the most effective covers to reduce percolation of rain through the covered soil. Since lead and arsenic in low concentrations are not leachable, engineered caps have some limited use at the Site.

A.4.3 Liner

Liners are characterized by a physical barrier between the impacted medium and the underlying soil or groundwater. The main purpose of the liner is to reduce water movement from an impacted zone to clean zones. Usually, the impacted soil is placed in a prepared, lined basin and eventually capped. Liner materials include **synthetic membrane** and **clay** although often a combination of the two is used (**multimedia liner**) (EPA, 1985). Unless a nearby source of clay is available, clay is not usually economical. There is no ready source of clay near the Site. DNT is the only constituent at the Site that is leachable and it has been almost entirely removed during interim source removal. Consequently, a liner would have limited use as a containment technology. A lined basin may be considered for on-Site placement of stabilized concentrated fines but an engineered cap over the stabilized soil would prevent infiltration and leaching more cost effectively. Liners will not be retained for further analysis.

***In Situ* Liner** can be created using **grout injection**. In this process, low permeability grout is injected in a grid pattern across the Site. The grout permeates the soil underlying the impacted zone creating a continuous layer of very low permeability material. The biggest advantage of this method is that the impacted soil does not have to be excavated. This can be important if the contamination extends to a great depth. Disadvantages include expense and ensuring that the grout layer is continuous. This method is not appropriate for the Site where most of the constituents are located in the upper foot of soil.

A.4.4 Cap/Cover

Cap/Cover is the combination of an engineered cap or liner and soil cover. It prevents direct contact with the covered soil and provides a good substrate for vegetation. As vegetation will prevent erosion, limited/little maintenance of the soil cover may be required. It is an effective low cost option when no leachable constituents of concern are present.

A.5 Dust Control

Dust control is typically important only during cleanup action (excavation, screening). There are two basic types of dust control: binding agents and barriers.

Water Spraying: This is the most common binding agent used for dust control. It is used on virtually all construction jobs. It has the disadvantage that it is temporary and requires frequent reapplication. Applied at the correct flow rate, the water will not infiltrate to the groundwater.

Dust Suppressants: Chemicals or binding agents such as liquid asphalt last longer. These have the disadvantages that they may be toxic and are more expensive than water. Biodegradable dust suppressants are available, such as wood fiber suspended in water. This material is sprayed over the surface, as for water, to form a protective crust, although it does not dry as quickly. Because the dust suppressant caps are typically thin, they are susceptible to cracking, especially under traffic loading.

Wind Fences: A wind fence is a barrier that is placed around the perimeter of the area to be protected. It deflects the wind from the susceptible area preventing it from entraining dust particles. Wind fences are useful when constant activity prevents covering of susceptible areas and the wind blows from a constant direction. These are unlikely conditions at the Site; therefore, this option will not be considered in further analyses.

Plastic Covers: Plastic covers are another form of barrier. When soil piles sit for long periods of time, they can be covered with plastic. Plastic covers are effective regardless of the direction the wind is blowing. Plastic covers are currently used on the soil stockpiles at the Site.

Vegetation: One type of permanent dust control is vegetation. Vegetation can work both as a binding agent and as a barrier. Plant roots bind soil particles to the surface at the same time that the plant above the ground reduces near-surface wind speeds. Site development is expected to include landscaping and vegetation. Hydro-seeding may be used to establish a grass-type vegetation after cleanup action and before landscaping. Since vegetation is already part of the Site development plan, it will not be carried into further analyses.

A.6 Removal

Removal is a rapid method to move the soil from the uncontrolled environment of the impacted site to a controlled treatment or disposal area. Except for *in situ* methods, removal is required for all remedial alternatives.

Removal technologies do not change the nature of the constituent but reduce risk when combined with treatment or disposal technologies.

Excavation of impacted soils can normally be accomplished with conventional construction equipment such as scrapers, backhoes, bulldozers, and front-end loaders. Some excavation is required for virtually all remedial alternatives except No Action. In some special situations, such as on steep slopes, or near buildings and utilities, special equipment may be necessary.

A.6.1 Excavation and Off-Site Disposal

Off-site disposal is a proven, effective remedial technology. Sites can be quickly and permanently cleaned up, although the nature and toxicity of the constituent is not changed. The main disadvantage of off-site disposal is the potential liability associated with mismanagement of the contained waste in the receiving landfill.

Hazardous Waste Landfill: Disposal in a hazardous waste landfill is a proven technology. This type of management is usually reserved for wastes that have been characterized as state dangerous or RCRA (federal) hazardous wastes based on their properties or characteristics or because they have been explicitly listed in state and federal hazardous waste regulations (e.g., Chapter 173-303 WAC and 40 CFR Parts 260 through 270). Thus the properties, characteristics, or constituents of these hazardous wastes warrant special, RCRA landfill disposal requirements.

The EPA Land Disposal Restrictions (LDRs) require that hazardous wastes be subjected to minimum levels of treatment and/or contain minimum concentrations of hazardous constituents before they, or residues from their treatment, can be land disposed of. Off-site land disposal of soils that are hazardous wastes may require treatment of concentrations that are above LDR concentrations.

Solid Waste Landfill: This technology involves disposal in a lined landfill with a leachate collection system. Solid waste landfills are the prime repository for municipal trash and garbage. Some solid waste landfills also accept industrial waste including problem waste.

Chapter 173-304 WAC defines problem wastes as "(a) soils removed during the cleanup of a remedial action site, or a dangerous waste site closure or other cleanup efforts and actions and which contains harmful substances but are not characterized dangerous wastes, or (b) dredge spoils..." Regulations that deal specifically with problem waste (PW) management and disposal have not yet been developed (as of March 1994). Disposal as a PW may be suitable for stabilized soil which passes the toxicity characteristic leaching procedure (TCLP) tests or for mixture of non-hazardous impacted soils with constituent concentrations above the Cleanup Standard.

Demolition Debris Landfill: Demolition debris landfills are unlined. Debris landfills have been used for debris disposal during interim source removal and additional disposal of non-hazardous debris is anticipated as part of future cleanup action. Disposal of the Site soils in this type of landfill would not be appropriate.

A.7 Immobilization

Immobilization is a response action designed to accomplish at least one of the following (EPA, 1986):

- Improve the handling and physical characteristics of the soil;
- Decrease the surface area available for the transfer of constituents from the soil; and/or
- Limit the solubility of the constituents in the soil.

Immobilization is often used in conjunction with disposal of material in a commercial landfill (EPA, 1985).

Immobilization encompasses two technologies: solidification and stabilization (or fixation). The emphasis of the first is to create a high strength material which will reduce the exposure to the impacted soil by direct contact. The second technology focuses on reducing the constituents mobility within the matrix. Those two technologies overlap as some solidification reagents also have a fixation effect and vice versa. Often, both effects are desired. Consequently, solidification and stabilization will be considered as one technology.

A.7.1 Solidification/Stabilization

Common solidification reagents include **Portland cement** and **silicate-based** materials like fly-ash and polysilicate mixtures. These reagents have been used for many years in road construction and also provide stabilization for certain metals. Portland cement is effective to fix lead, and arsenic has been successfully stabilized with a polysilicate mixture.

Arsenic chemistry is complex, involving a variety of valence states and ionic species, and both inorganic and organic species. Arsenic oxides and sulfides can be stabilized but not the organic species (contained in herbicides). The arsenic oxide (found in flue dust from non-ferrous smelting operations) is soluble in both acid and basic environments. Lead is soluble mostly in an acid environment. The range of pH in which both lead and arsenic oxide will be stabilized is narrow. The stabilization of arsenic oxide and lead-impacted soil is difficult.

Mix design for solidification must be determined by bench-scale testing with the actual Site soil.

Other, innovative techniques include **thermoplastic** solidification and **encapsulation**. In thermoplastic solidification, the soil is sealed in a matrix such as asphalt bitumen. This technique requires specialized equipment. Asphalt incorporation is a thermoplastic solidification method which is also a recycling process for the impacted soil. It can be applied only to soil passing TCLP tests and therefore is unlikely to be an option for most soils above the statistical action levels (SALs). Encapsulation uses an organic binder or resin to physically contain waste materials either by containing individual soil particles or a cluster of particles. The encapsulation processes are generally proprietary and expensive.

Cryogenic encapsulation is a temporary solidification process only. A large power supply is required to keep the ground frozen. No temporary solidification is required at the Site; therefore, this process will not be further analyzed.

One common method of fixation is to use **sorbents,** such as fly-ash or bentonite, to absorb free liquid and produce a solidified waste. Other additives can be use to chemically fix constituents by forming an insoluble precipitate or complex. Many proprietary mixes exist to fix various constituents. This technology is not applicable at the Site since the impacted soils do not contain free liquids.

Fixation can be also be achieved *in situ* or *ex situ* by **surfactant fixation**, often a proprietary process. This technology utilizes the application of specific inorganic and organic reagents which readily percolate through the impacted soils. They reduce heavy metals to their lowest valence state and render them insoluble as stable organometallic complexes. The detoxified soils achieve the TCLP requirements and are no longer leachable. This technology has been demonstrated only for low metal concentrations (lead and cadmium: 10 to 15 mg/kg) and may require toxic amounts of surfactant at higher concentrations. This technology will not be retained for further analysis.

Surface Soil Fixation employs soil mixing and grinding with addition of a fixating agent to homogenize concentrations in the surficial soil and stabilize the metals. The homogenization action results in a reduction of isolated elevated concentrations in the surficial 6 inches of soil. The fixating agent may be a constituent modifying the pH of the soil thus lowering the leachability potential of the metal or a proprietary additive forming a chemical bond with the metal for stronger fixation. Proprietary additives for strong fixation may not be necessary since none of the TCLP results for arsenic were above the limit of 5 mg/L. Surface soil fixation could be applied to mitigate direct contact risk by aggregating the fines. The addition of cement can result in the formation of a granular material that could be used as a subgrade under areas such as parking lots.

In situ **Vitrification (ISV)** is a process whereby impacted soils are melted with a high electrical current and then allowed to cool to form a stable glass-like material. ISV is a patented process developed by Battelle Pacific Northwest Laboratory for the U.S. Department of Energy as an in-place stabilization technique (Hansen, 1988). At the high temperatures created (over 1,700 degrees Celsius), organic

material undergoes chemical change by pyrolysis (thermal destruction in the absence of oxygen). The products of pyrolysis rise to the surface as off-gases which must be collected, monitored, and treated. Inorganics are immobilized by chemical incorporation in the melt and solidified with the residual product. The residual ISV product offers 20 to 45 percent volume reduction, and excellent structural, weathering, and biotoxicity properties.

Full scale tests with ISV have been conducted on a variety of soil types (Fitzpatrick et al., 1986; Timmons, 1989). The full scale unit has four electrodes spaced about 18 feet apart. This results in a melt zone about 30 feet wide.

Buried metal in the soil can cause short-circuiting problems for the ISV process depending on the physical state of the objects. Fitzpatrick et al. (1986) states that soil with up to 5 percent metal, by weight, can be vitrified. In recent tests, soils with up to 15 percent metal, by weight, have been successfully melted (Timmons, 1989).

In situ vitrification is not an appropriate process for the Site since most of the metal contamination is distributed in the first foot of soil.

A.8 Treatment

Treatment technologies permanently reduce the toxicity and/or volume of the constituent or impacted material. The cleaned soil can then be returned to the site, disposed of as clean fill, or placed in a landfill. Treatment technologies for metals-impacted soils include recycling, and thermal and soil washing processes.

A.8.1 Recycling

Lead Smelter: Recycling lead-impacted soil to a smelter involves recovery of lead from the soil by the same process which extracts lead from ore. A minimum soil lead content of 10 percent by weight is expected to be required for acceptance by the smelter. The presence of other metal constituents may be problematic as they would volatilize, remain in the slag as a waste product, or impact the quality of the lead metal product.

Cement Kiln: Impacted soil could also be recycled to a cement kiln where the volatile metals would be removed in the off-gas and recovered in the baghouse, and the heavy metals incorporated into the cement at low concentrations. The soil would have to pass the TCLP tests before being accepted by the cement kiln. This is an unlikely option for Site soils.

A.8.2 Thermal Treatment

Thermal treatment does not destroy metals. Lighter metals will volatilize, heavy metals will remain in the soil. Important concerns are potential air emissions and the liability associated with the residuals.

In general, thermal treatments are characterized by high costs based on energy consumption.

Slagging with Off-Gas Treatment: This process is a two-stage, high temperature system. The temperature inside the reactor section is between 1,400 and 1,850°C. In the high-temperature reducing atmosphere, metals such as lead, arsenic, and cadmium are vaporized from the waste. Less volatile metals such as copper, nickel, and cobalt, if present in sufficient quantities, coalesce as a molten alloy phase. The remaining components of the waste, which may include metal oxides such as those of iron, melt in a molten slag.

Products from the reactor are passed to a slag separator. The process gases are drawn from the slag separator through the off-gas system where the vapors are post-combusted with ambient air and condensed as metal oxides. The gases are subsequently cooled, and the mixed metal oxide particulate is collected in a baghouse before discharge to the atmosphere. This process significantly reduces the

volume of impacted material. The metal oxide particulates and the slag are withdrawn from the reactor and recycled or disposed of according to their toxicity.

Fixed and transportable full-scale treatment units exist. Their maximum treatment rate is 2.5 tons per hour, which will not be adequate to treat all the impacted soils within a reasonable time frame. This process will not be retained for further analysis.

Thermal Desorption: As mercury is fairly volatile compared to other metals (boiling point 356.9°C), thermal desorption can be used to recover it from soil. The impacted soil is heated to the point where mercury begins to volatilize; the vapors are collected and treated to recover the mercury. This process is only applicable to mercury and would leave other metals in the soil. As only small amounts of mercury contaminated soils occur on the Site, this technology was not retained for further analysis.

Hydrogen Volatilization: Hydrogen volatilization is a process in which lead is recovered by high temperature distillation in hydrogen. It is an experimental technology demonstrated only in the laboratory and will not be retained for further analysis.

A.8.3 Physico-Chemical Separation

Physico-chemical separation removes the constituent from the medium with a combination of physical (scrubbing, classifying) and chemical processes (solvent extraction, solubilization).

Solvent or Chelant Extraction: Soil is placed in a tank with a solvent or chelant. The mixture is agitated, and the solvent or chelant is used to extract the constituent from the soil matrix. Clean soil is returned to the Site and the solvent or chelant is treated to remove the constituent and is recycled. Concentrated residues from the solvent/chelant recovery process are then further treated or disposed of. EDTA, citric acid, and other solvents and chelants have been used with various metals. Solvent/chelant extraction is site-specific and generally requires a pilot study prior to system design. It has the advantage of returning most of the soil, clean, to the Site.

Solvent/chelant extraction is generally done in a batch process, where a volume of soil is placed in a mixing tank in one batch, treated, and then removed. Each batch of soil may be washed more than once with fresh solvent.

***In Situ* Extraction:** In this process, lagoons are constructed over the impacted area. Water is allowed to infiltrate through the impacted soil into the underlying groundwater. The groundwater is then extracted for treatment and recycled back to the lagoons. This is a very simple process that is most useful when groundwater contamination already exists. If not, there is a risk of not capturing all of the infiltrating water and causing a groundwater problem. Another disadvantage is that fine-grained soils can greatly slow the process. Because contamination at the Site is shallow and water is a poor solvent for metals, this technology was not retained for further analysis.

Acid or Base Extraction: Impacted soils are washed with an acid or base leaching solution to concentrate the metals in solution. Other chemicals can be added to facilitate metals solubilization. The washed soil is then separated from the leaching solution and the soil may require neutralization before being backfilled on the Site. The solution is treated to recover the metals, by precipitation, reverse osmosis, or ion exchange. Precipitation produces a sludge containing the metals which can be recycled or disposed of at a RCRA landfill. Selective ion exchange can recover individual metals but is only cost-effective for recovery of precious metals. Reverse osmosis produces a concentrated solution of metals which requires further treatment. Acid extraction has been demonstrated as effective for lead. Most arsenic chemical constituents are not removed by acid. Basic solutions are more effective. As for solvent or chelant extraction, acid/base extraction has the advantage of returning most of the soil, clean, to the Site.

Electrical Separation: Electrokinetic soil processing is an *in situ* semi-continuous process for the removal of heavy metals, radionuclides, and organic bases from fine-grained silty clays. The application of a low intensity, direct current applied across the impacted soil, results in removal of the constituents through mass transfer mechanisms of diffusion, and ion migration. The pollutants present in the soils are removed in cycles. One cycle will typically capture 75% to 95% of the original constituent and will require 2 to 3 months. Each cycle involves application of direct current, removal of the constituents at the cathodes in either soluble or precipitated forms, and replacement of the lost soil moisture.

This technology is not cost-effective in sands and gravels and therefore not applicable to the Site.

Screening: Screening is a common pretreatment process for other types of treatment since oversized particles cannot be processed by equipment associated with soil washing and thermal treatment methods. In this process, soil is fed into a wire mesh screen to remove oversized particles. Most metal constituents in soil are bound up in the finer fraction of soil particles so screening also reduces the volume of impacted soil by removing the larger particles which do not exceed the Site-specific remediation levels.

Screening can be a dry or wet process depending on the degree of separation sought. Dry screening will not remove all the fines from the cobbles/gravel, especially if the soil is moist. Its advantage is that water handling is avoided. Wet screening uses water spray to wash the fines off the gravel and improve the degree of separation. The wash water will be carried with the fines and may require treatment. Wet screening generally allows separation to a finer mesh than dry screening.

Classification: Classification is a group of water-based processes which typically uses mineral processing technology (jigs, spirals, flotation, hydrocyclones, attritioning). The process generates a clean soil fraction, an impacted sludge or cake consisting of soil fines, other concentration material, and process water. The waste and concentrates may require treatment prior to recycling. The sludge may be recycled to a lead smelter (if the lead is highly concentrated) or a cement kiln, or disposed of in a RCRA landfill. A pilot-scale test is necessary to determine the feasibility of this technology for a given soil. Classification has the advantage of returning a large fraction of the soil, clean, to the Site while not involving the handling and treatment of chemicals (solvent, acid, or base). Classification may be a more or less complex process depending on the concentration rate desired and the equipment required to achieve that concentration.

APPENDIX B – *OVERVIEW OF SOIL TESTING PROCEDURES AND DATA INTERPRETATION*

B.1 Whole Soil Procedures

Sample Preparation: Upon receipt, the soil sample was coned and quartered, and blended and split to produce a more homogeneous head sample.

Stage Crushing: Throughout the course of this program, samples assayed for chemical constituents were crushed prior to analysis. The fines were separated out and the oversize was crushed again. The entire process was repeated until the desired particle size was achieved. This helped to ensure that a representative sample was assayed.

Sample Verification Testing: After sample preparation, three grab samples were collected. Each sample was analyzed for total lead. The TCLP was performed on a composite of the three samples, with leachate analysis for total lead. These analyses were performed on a rush or priority basis to check whether the lead sample collected was representative of the lead concentrations at the Site, based on the results of previous sampling events.

Moisture Content: The sample was air dried and the moisture content was reported as a percent weight loss. This provided an indication of how wet or sticky a soil was and how dry that soil can be made by stockpiling in a dry area. This information was useful for materials handling and technology selection.

Soil Bulk Density: This parameter, measured as kilograms soil per cubic meter, provided an exact conversion from volume to weight. Loose density was representative of soil in an excavated condition, while packed density was representative of *in situ* conditions. The sample for packed density measurement was not compressed, but was prepared by tapping the container so that the soil settled.

Soil Plasticity (Atterberg Limits): The liquid and plastic limits, and plasticity index are qualitative measurements indicating soil plasticity. This information provides an indication of how sticky the soil is, and how it deforms and flows (rheology). The information was used for identification and classification of fine-grained soil and clays. It was useful for materials handling, when choosing excavation and mixing equipment for implementation of treatment technologies.

Particle Size Distribution: Soil was divided into approximately nine size fractions ranging from cobbles/gravel, coarse to fine sands, and silt/clay by wet screening. The particle size distribution was used in determining the USDA soil classification. Each size fraction and the residual water were then analyzed for total lead. The weight and lead distributions were reviewed to determine which particle size fractions contained the lead and which fractions are "clean". This information was used to evaluate the effectiveness of soil washing and the quality of the wash water. Highly contaminated fractions may be further analyzed for lead species.

Standard USDA Soil Classification: The soil classification was determined from the soil particle size distribution, plasticity information, and visual observation. The various groupings of this classification system was devised by the ASTM committee to correlate in a general way with the geotechnical engineering behavior of soils. The classification was useful in understanding the behavior of the soil in materials handling and treatment processes.

RCRA Appendix IX Semivolatile Organic Compounds: This information was needed for regulatory purposes and constituent screening. Information on concentrations of semivolatile organic compounds is also important when evaluating treatment technologies, since they may interfere with performance or may be released as emissions. Samples were not assayed for volatile organic compounds, since many of the

sample homogenization and preparatory procedures permit volatilization. Additionally, samples were not assayed for pesticides, herbicides, PCBs, dioxins, and furans, since historical evidence and prior analyses do not indicate the presence of these constituents at the areas studied at the Site.

RCRA Appendix IX Inorganic Compounds: This information was needed for regulatory purposes and constituent screening. While this study was primarily concerned with lead-affected soils, the soils in the study contained other metals of regulatory concern. Treatment processes which concentrate lead or extract/leach lead in a particular soil fraction (soil washing) may also concentrate or extract other heavy metals.

Soluble Cations: Calcium, sodium, magnesium, and potassium were measured. These soluble cations can impact the system solubility and compete with heavy metal constituents for binding/bonding sites and anionic species. In general, cations are retained in soil types with higher clay content and surface area. Cations exhibit relatively low mobility in clay and silty clay soils and moderate to high mobility in sandy, loamy sand, and sandy loam soil.

Anions: Sulfide, sulfate, phosphate, carbonates, and bicarbonates are naturally occurring anions in soil which provide bonding and binding sites for heavy metals and soluble cations. In general, anions exhibit relatively low mobility in clay and silty clay soils and moderate to high mobility in other soil types.

Carbon Content: Total carbon is measured from the carbon dioxide evolved during combustion of a sample in an oxygen atmosphere. Inorganic or fixed carbon is determined by thermal gravimetric analysis (TGA). TGA involves heating a sample under an argon atmosphere at a known rate until first the moisture and then the volatile matter are driven out of the soil. Air is then introduced to oxidize any remaining material (fixed carbon) until only the ash remains. Inorganic (fixed) carbon is reported as a weight percent of the original sample. Organic carbon is determined to be the difference between the total and inorganic carbon. Organic carbon content is another indication of the soil's natural ability to bond and bind with constituents. Carbon content information was useful in evaluating both stabilization and soil washing technologies.

pH: This is a measure of the acidity or alkalinity of the soil. This information was used to determine whether the soil is RCRA hazardous because it exhibits the RCRA characteristic of corrosivity. Initial pH of the soil is a useful piece of information needed in calculating stabilization mix designs or in determining the effectiveness of acidic or basic soil washing.

Redox Potential: This is a measure of whether the soil is in an oxidizing or reducing state. Several elements can exist as part of the structure of soil minerals in more than one oxidation state. For example, manganese (Mn) can exist in soil as Mn+2, Mn+3, or Mn+~. Arsenic (As) can exist as As+5, or As+3. The particular species which will be present depends upon the oxidation-reduction (i.e., redox) status of the soil.

Acid-Base Potential: This is a quantitative measure of the soil's buffering capacity. The amount of neutralizing bases present in the soil are reported as tons of calcium carbonate per 1,000 tons of soil. A positive number indicates that the soil is basic. Conversely, a negative number indicates that the soil is acidic. A close relationship exists between the total sulfur content of the soil and the net potential acidity. This information was useful in calculating stabilization mix designs or in determining the effectiveness of acidic or basic soil washing.

Generalized Acid Neutralization Capacity (GANC) and Reverse GANC: This test is a single-batch leaching procedure that utilizes a series of dried samples extracted for a 48-hour time period with an increasingly acidic leachant (or an increasingly basic leachant for the reverse GANC). A 20:1 liquid to solids ratio was used to duplicate the conditions of the TCLP. Equivalents of 2N acetic acid (or 2N sodium hydroxide per kilogram of dried solids) are plotted versus final solution pH. This information indicates the

buffering capacity of the material, and can be used to calculate stabilization mix designs or to determine the effectiveness of acidic or basic soil washing.

Metals with Acid Neutralization Capacity (MANC) and Reverse MANC: This test quantifies the concentration of a metal released when an amount of acetic acid (or sodium hydroxide) in equivalents is used to reduce (or increase) the pH of a solution. For each acidity (or alkalinity) value of the GANC (or reverse GANC), the concentration of a metal released was measured after a 48-hour time period. Equivalents of 2N acetic acid (or 2N sodium hydroxide) per kilogram of dried solids are plotted versus the concentration of a metal. While the GANC plot depicts the relationship between acid (or base) addition and pH (buffering capacity), the MANC plot depicts the relationship between acid (or base) addition and metal concentration (solubility). When the GANC and MANC are plotted on the same figure, the minimum solubility point for a metal is shown to correspond to a specific pH range. This information was used in calculating stabilization mix designs and in determining the effectiveness of acidic or basic soil washing (based on solubility of metals).

Toxicity Characteristic Leaching Procedure (TCLP): The TCLP is designed to determine the mobility of constituents in a waste. A solid waste exhibits the RCRA characteristic of toxicity if, using the TCLP test procedures, the extract from a representative sample of the waste contains any of a set list of constituents at or above certain concentrations. This information was required for regulatory classification, and proper handling and disposal of the waste soil. The TCLP and associated criterion may be used to set the remediation cleanup goals. The TCLP was used as a measure of the chemical performance of treatment technologies. Since the TCLP is an extremely aggressive acid equilibrium leaching procedure (20:1 liquid to solid ratio, small solid particle size, and 18-hour contact time), the TCLP results may also be used to calculate distribution coefficients, if the initial constituent concentrations are known.

Equilibrium Leaching Procedure (ELP): This is a leaching procedure that uses synthetic acid rain (SAR) to simulate weathering conditions at a site. It uses the same solid particle size and liquid to solid ratio (20:1) as the TCLP; however, it provides a more realistic leaching scenario since it uses 60% sulfuric acid/ 40% nitric acid SAR (instead of acetic acid) and a contact time of 96 hours (instead of 18 hours) to further ensure that the leaching is more realistic of site conditions and has been given time to achieve equilibrium. Lead assays are performed on both the leachate and solids to provide a complete mass balance for the calculation of distribution coefficients.

Surface Area Calculations: For each soil fraction or particle size range, the amount of surface area was calculated in square meters per kilogram. The smaller the particle size, the larger the surface area. Based on the weight distribution of the various soil fractions, the surface area distribution was calculated. In general, the majority of the surface area are associated with the fines or silt/clay fraction. The fine particles often exhibit adsorption, cation exchange capacity, and other binding and bonding properties.

B.2 Soil Fraction Procedures

FO39 List Metals: Treatment processes which concentrate lead or extract/ leach lead in a particular soil fraction (soil washing) may also concentrate or extract other heavy metals. This information was needed for constituent screening and regulatory purposes, to ensure proper handling and disposal of the soil.

Chloride: This is a naturally occurring inorganic anion which can affect the mobility of constituents. Chloride compounds are very soluble and therefore very mobile. This information was useful in determining the species and mobility of metals and, therefore, the impact to the environment.

Iron and Manganese: Heavy metals can bond and bind with iron-manganese oxide surfaces in the soil. This information was useful in determining the species and mobility of metals and, therefore, the impact to the environment.

Cation Exchange Capacity (CEC): The CEC is defined as the total amount of water soluble cations adsorbed by negative charges on a unit mass of soil. In general, the silt/clay fraction exhibits the highest CEC, since it has the most surface area. The adsorption process is reversible, and the equilibrium relationship can be expressed by K_d, the distribution coefficient. CEC is one component of the soil that is responsible for the soil's buffer capacity. Buffering mechanisms that involve metal cations in solution are affected by the extent of adsorption to cation exchange sites on soil particle surfaces. In arid regions, the accumulation of calcium, sodium, magnesium, and potassium salts may result in the saturation of a soil's cation exchange capacity with these cations. The tendency for these cations to produce hydroxide ions is the factor controlling the amount of hydrogen ions in the water phase of the soil (and thus the pH). Carbonate minerals (calcium carbonates, sodium carbonates, and magnesium carbonates) can buffer the hydrogen ion content (pH) of water in a soil system.

Sequential Extraction: This procedure is a wet chemical method in which a series of specific reagents is sequentially applied to a soil sample, and the lead content is measured in each extractant. Each reagent selectively removes lead that has been bound or adsorbed to the soil matrix in a specific way. The sequence of reagents is such that each reagent is more aggressive than the previous one. The results of this test indicate the species of lead present and the way in which the lead is bound to the soil. This information was valuable in determining impact to the environment and in evaluating treatment technologies.

Scanning Electron Microscopy (SEM): SEM is a sophisticated technique to determine constituent species by viewing the material under extremely high magnification. SEM analyzes individual soil particles and can identify both crystalline and amorphous structures. This information on constituent species was valuable in determining mobility and impact to the environment, and in evaluating treatment technologies.

X-Ray Fluorescence (XRF): This scan is performed to determine soil mineralogy. While the results are reported as compounds (mainly oxides and metals), the scan actually identifies major, minor, and trace elements (approximately 40). Results are reported as a weight percentage of the total sample. Carbon dioxide is also analyzed by a coulometric method, to aid in the material balance. The difference between the total weight of the soil and the weight percentage of minerals may be attributable to water. Information on soil mineralogy aids in the understanding of soil/ contaminant interactions including contaminant species, binding/bonding and mobility.

APPENDIX C – *LEAD AND ARSENIC SOIL CHARACTERIZATION AND TREATABILITY STUDIES*

C.1 INTRODUCTION

Treatability studies were performed to assist in the selection of appropriate Cleanup Actions for impacted soils at the former DuPont Works Site (the "Site"). The studies were selected to address constituents impacting significant soil volumes; these constituents were lead and arsenic. This document will address: the requirements for treatability studies; the basis for treatability study selection and design; the treatability study approach and initiatives taken; a summary description of the treatability studies completed and the study results; a summary of interpretations made; and finally, conclusions drawn from the treatability studies and recommendations for additional treatability work.

C.2 TREATABILITY STUDY REQUIREMENTS

The specific requirements of the treatability studies were determined based on the need to generate technical data to assist with the screening and selection of potential soil remediation technologies for lead- and arsenic-impacted soils. The lead and arsenic studies were designed with regard to the principal candidate technology categories identified through preliminary Feasibility Study (FS) screening. Chapter 4 provides an overview of the type of data required to assess the effectiveness of these types of technologies. The constituent-specific portions of Chapter 5 (5.3 and 5.4) contain a discussion of the treatability study results and their relevance to the evaluation of each technology category.

The treatability studies were carried out to meet the objectives described in Chapter 3. They include characterization studies performed by Hazen Research, Inc. (Hazen), in addition to speciation work, screening studies, and bench-scale technology evaluations performed by Hart Crowser, Battelle Pacific Northwest Laboratories, the State University of New York, the University of Cincinnati, and Weyerhaeuser Analytical and Testing Services.

C.3 BASIS FOR TREATABILITY STUDY SELECTION AND DESIGN

C.3.1 Treatability Study Objectives

The general objectives of the overall treatability study program, together with specific objectives with respect to soil characterization, are set out below.

- Provide sufficient information necessary to fully define the soil remediation problems presented and determine the specific requirements of the candidate technologies.

- Expedite the evaluation process prescribed by Model Toxics Control Act (MTCA) and so assist the selection of appropriate Cleanup Action Alternatives (CAA's) for soils impacted by the major constituents of concern, i.e.,
  - Provide information/data on treatment technology effectiveness;
  - Enable CAA's to be compared and evaluated on an equal basis;
  - Provide, in conjunction with available relevant literature, sufficient characterization and performance data to allow treatment alternatives to be developed and evaluated during FS detailed analysis;

- Help reduce performance uncertainties for treatment alternatives to acceptable levels to enable remedy selection; and

- Support the Interim Source Removal program.

- Provide preliminary supporting data for the design of selected CAA's and help define further data requirements needed prior to Cleanup Action implementation.

Specific soil characterization objectives are:

- To help fill gaps in physical and chemical Site characterization data pertinent to soil handling and to the treatment options developed;

- To determine, in detail, the physio-chemical nature of constituent/soil matrix interactions and thereby answer basic questions regarding constituent distribution and speciation, soil bonding/binding characteristics, and constituent leachability/mobility; and

- To provide information on the prospects for reducing volumes of significantly impacted soils through the use of physical screening techniques to segregate soils by particle size.

C.3.2 Rationale and Constraints

The rationale for the selection and design of the treatability study program was based on several basic criteria. These criteria, which in some cases represent constraints on the scope of the program, are summarized below.

- The treatability studies should address the major constituents of concern under the FS, i.e., those impacting significant (greater than 5,000 yds^3) soil volumes at levels exceeding the Working Hypothesis screening levels. These constituents of concern are lead and arsenic.

- The studies should be tailored to obtain appropriate data to assist in the determination of the technical viability of the principal candidate remediation technology categories identified through preliminary FS screening (see Chapter 2). The range of data obtained via the studies should reflect the broad range of innovative technology types and treatment approaches under consideration.

- The studies should be capable of fully characterizing the impacted soil matrices and the complex soil/chemical interactions (this criterion is further addressed in the opening discussion under Section C.4 below).

- The scope and duration of the studies should be consistent with the schedule for completion of the Remedial Investigation (RI) and FS activities.

C.4 TREATABILIITY STUDY APPROACH AND INITIATIVES

U.S. Environmental Protection Agency (EPA) analytical protocols are widely used in environmental remediation programs to determine the appropriate designation of potential 'waste' materials. These protocols include measuring the total or leachable concentrations of chemical constituents in the subject material (e.g., using SW-846 and Toxicity Characteristic Leaching Procedure (TCLP) methods), as well as testing the material for the characteristics of ignitability, corrosivity, reactivity, and toxicity. The protocols are designed to assist in determining whether any regulatory waste classification is applicable, so that the material may be managed, treated, and disposed of appropriately.

However, when dealing with a complex matrix such as soil impacted by chemical constituents, additional characterization information regarding physical and chemical properties and constituent/soil interactions is needed. In addition to assisting the assessment of regulatory classification, potential impact to human

health and the environment, and decisions regarding cleanup goals, this information is necessary to thoroughly evaluate which treatment technologies and processing conditions are applicable.

In this case, the treatability study approach principally involved a series of carefully devised laboratory tests directed at detailed characterization of representative soil samples impacted by the major chemical constituents of concern. The characterization testing program was designed with emphasis placed on the examination of complex soil/constituent (metal) interactions. The types of soil characterization information obtained relate to how constituents are held/bound in the soil matrix, what chemical form (speciation) constituents exist, and in what soil fractions (distribution) they reside. Associated information was also obtained to describe the soil composition (chemical and mineral content as well as particle size distribution) and assess the mobility/leachability of the bound constituents. The overall intent of the soil characterization studies was to provide a wide range of physical and chemical data giving insight into the viability and suitability of the principal candidate remediation technology categories referenced in Chapter 2, and to provide an efficient and cost-effective means of narrowing the field of potential Cleanup Action Alternatives. The physical analyses were primarily aimed at providing data, which will indicate how the soils will behave physically during materials handling, and physical treatment steps, while the chemical and speciation analyses were directed more towards identification of technological applicability.

The soil characterization methods and procedures described, by category, in the following paragraphs were selected for use in the lead and arsenic constituent initiatives, based on their ability to physically and chemically characterize metals-impacted soils. Further information is provided in Tables C-1 and C-2, "Soil Characterization Procedures", which lists each of the analyses included in the characterization studies (performed by Hazen), and specifies the type of information that can be determined from each analysis. The three categories presented below are used as the basis for the presentation and discussion of the treatability study results in Section C.5.

C.4.1 Regulatory Analyses

Regulatory analyses are designed to determine the regulatory classification of the waste, so that the waste may be managed, treated, and disposed of properly. Regulatory analyses include the RCRA Appendix IX list inorganics and semi-volatile organics. The Toxicity Characteristic Leaching Procedure (TCLP) was performed to determine whether the soil exhibited the RCRA characteristic of toxicity, and therefore should be assigned an EPA Characteristic Hazardous Waste Number.

C.4.2 Physical Analyses

Physical analyses are aimed at gathering data to indicate how the soil will behave physically during excavation, materials handling, and treatment processes. The physical analyses include particle size distribution and Atterberg limits (liquid limit, plastic limit, and plasticity index) that are used to determine the standard USDA soil classification. Other physical properties measured are moisture content and bulk density of both loose and packed soil.

C.4.3 Chemical Analyses

Chemical analyses are aimed at gathering information on soil chemistry, soil mineralogy, soil/constituent interactions, and constituent distribution, speciation, and mobility. The pH and Generalized Acid Neutralization Capacity (GANC) are measured of the soil's alkalinity or acidity and inherent buffering capacity. GANC and Reverse GANC data can also be used to assist the potential effectiveness of stabilization and soil washing/leaching treatments. The TCLP and Equilibrium Leaching Procedure (ELP) are both measures of leaching or mobility of the constituent. Organic carbon and anions can bond with heavy metals, reducing their mobility. Soluble cations can compete with heavy metals for bonding sites, increasing heavy metal solubility. X-ray diffraction, scanning electron microscopy, and sequential extractions are all used to determine which specific chemical form of the metal is present in the soil and how it is bound

The data quality objectives under the characterization studies were primarily to generate high quality technical data for use in performing evaluations and supporting positions developed under the FS. Only those procedures intended to determine the regulatory classification of the soil were performed strictly according to EPA SW-846 protocols. Under subcontract to Hazen, Evergreen Analytical, Inc. performed the regulatory analysis for the RCRA Appendix IX total inorganics (including lead, arsenic, and mercury) and semi-volatile organics, TCLP, and TCLP leachate organics and semi-volatile organics. The remainder of the analyses, performed by Hazen, was not completed according to strict SW-846 analytical protocols; however, every effort was made to ensure high quality data were generated. This approach was consistent with the main goal of this program, to generate high quality analytical information for technology screening purposes, rather than to produce legally defensible regulatory classification data. All procedures are documented and commercially available.

To supplement the laboratory characterization testing outlined above, additional speciation screening studies, and bench-scale treatability work was carried out to assist with a more detailed examination of the viability of soil washing and solidification/stabilization technologies.

C.5 SUMMARY DESCRIPTION AND RESULTS OF TREATABILITY STUDIES COMPLETED

C.5.1 Introduction

The majority of the treatability study work is represented by the laboratory and bench-scale soil characterization studies performed under contract by Hazen at their facility in Golden, Colorado. These studies involved soil samples from Site Areas known to be impacted by lead and arsenic, and include detailed characterization and speciation analysis of the lead- and arsenic-impacted soils. Soil sampling for the characterization studies utilized a statistical procedure based on EPA SW-846 guidance, recognized technical literature on sampling and analysis, and the experience of the Project Team. The sampling procedure enabled recovery of representative composite samples of impacted soils from randomly sampled grids in designated Areas of the Site determined, from pre-RI and RI information, to contain elevated concentrations of lead and arsenic.

The Hazen studies were supplemented by several additional specific initiatives performed by other commercial organizations and Universities, as outlined in Section C.5.2 below. Sections C.5.3 and C.5.6 present summaries of the constituent-specific work, focusing on the Hazen characterization studies, and include interpretations of the treatability study data generated. In the case of the lead-impacted soils characterization study (included in Section C.5.3), the work was part of a broader multi-site program conducted by DuPont to characterized company-wide lead remediation needs. The scope and detail of the DuPont study were greater than necessary for the purposes of this FS; only pertinent parts of the study and results are summarized here.

C.5.2 Other Initiatives Supporting Hazen Studies

Hazen's work was supplemented with subsequent treatability study initiatives performed by other commercial organizations and Universities. These are listed below with a brief description of the study scope for each.

BENCH-SCALE SOIL LEACHING STUDY – STATE UNIVERSITY OF NEW YORK, BUFFALO

A screening evaluation of the non-proprietary soil leaching chemistries was performed by the Department of Civil Engineering at the State University of New York at Buffalo (UB). The efficacy of various soil washing extraction agents and leaching conditions were evaluated for removing lead from a lead-impacted soil sample (-8 to +200 mesh fractions) from Area 40 (Pulverizer) of the Site, provided by Hazen. The results of this soil leaching study are contained in the final report prepared by UB researchers entitled Evaluation of Soil Washington Extraction Agents ad Processes for Remediating Heavy Metal Contaminated Soil from Weyerhaeuser Area 40 Pulverizer," March, 1994.

SOLIDIFICATION/STABILIZATION SCREENING STUDY – UNIVERSITY OF CINCINNATI

The University of Cincinnati Center for GeoEnvironmental Science and Technology (CGEST) conducted solidification/stabilization screening tests on soil fines (-200 mesh) samples from Areas 36 and 40 (Glazemill and Pulverizer) of the Site provided by Hazen to evaluate the ability of three non-proprietary binder mixes to solidify and stabilize lead-impacted soils. The effects of lead-designed solidification/stabilization binder mixes on arsenic contained in the Area 36 sample were also investigated. The results of this screening study are contained in the final report prepared by CGEST researchers entitled "Solidification/Stabilization Screening for Integrated Lead Remediation Program", 1993.

BENCH-SCALE SOIL LEACHING STUDY – WEYERHAEUSER ANALYTICAL & TESTING SERVICES

To investigate the potential for utilizing non-proprietary leaching chemistries to remove arsenic from the Site soils, a leaching study was carried out at the laboratories of Weyerhaeuser Analytical and Testing Services (Weyerhaeuser ATS). Under this three-phase study, several leaching solutions were applied to -1/4" by +200 mesh fractions of combined soil samples from Area 18 and the Narrow Gage Railroad area. The effects of pH and liquid:solid ratio were investigated as well as performance under single-stage batch and simulated multistage countercurrent extraction regimes.

ARSENIC SPECIATION ANALYSIS – BATTELLE PACIFIC NORTHWEST LABORATORY

Battelle Pacific Northwest Laboratory (Battelle PNL) performed limited arsenic speciation analysis on soil samples from Areas 5, 25, 38, and the Narrow Gage Railroad area. The purpose of this study was to identify ionic species of arsenic and investigate the presence of organic arsenic forms in Site soils potentially impacted by acid production (Areas 5 and 25), the use of arsenic-based herbicides (Narrow Gage), or arsenic-based paint/ink (Area 38).

WET SCREENING TESTING ON ARSENIC-IMPACTED SOIL – HART CROWSER

Additional arsenic treatability studies were performed by Hart Crowser to better define the distribution of arsenic concentration with respect to soil particle size, through the use of particle size distribution testing and associated arsenic analysis of sized soil fractions. Samples were taken in the 250/500 – foot arsenic soil sampling grid area (including Areas 18 and 36) and the Narrow Gage Railroad area to supplement the results from the Hazen arsenic characterization study completed on samples from the same areas.

C.5.3 Lead-Impacted Soils

Fifty-five gallon composite soil samples were collected from each of the following Consent Decree Areas, one sample per Area: Area 7 (Kettle), Area 18 (Nitrator Number 1), and Area 36 (Lead Melting). Three soil samples were also collected from Area 40, one each from the Pulverizer, Glazemill, and Packhouse locations. The method of sample collection was detailed in the sampling plan for each Area; a brief summary is described below.

Previous sampling results were used as a basis for establishing sampling grids in each Area. For each grid area (containing 100 nodes), a random number generator was used to select 25 discrete sample locations. Sub-areas, within the identified Consent Decree Areas, shown by previous sampling results to exhibit lead concentration below the MTCA Method A screening level of 250 mg/kg were not included in the sampling regime. Only soils that contained lead concentrations greater than 250 mg/kg were included (i.e., "hot spots" were in effect, sampled).

The soil samples for each grid area were taken from shallow depth intervals that were chosen to represent the soil to be potentially remediated based on previous vertical delineation. Approximately two gallons of soil were collected from each of the 25 selected sampling locations. The 25 samples were then composited into one 50-gallon samples from each area samples were shipped to Hazen in 55-gallon drums.

Composite sampling was chosen to adequately represent each area because the resulting soil homogenization is a simulation of the mixing that would occur during full-scale excavation and ex-situ

treatment. It is not significant that this sampling approach did not allow a thorough evaluation of lead concentration variability on technology performance, since these issues will be addressed in any future pilot testing.

Upon receipt of the soil samples, Hazen personnel prepared and tested the samples as outlined in Figure C-1,"Flow sheet for Sample Preparation and Testing". Portions of the samples from Areas 36 and 40 (Glazemill and Pulverizer) were sent to CGEST for the solidification/stabilization screening study, and portions of the sample from Area 40 (Pulverizer) were sent to UB for the bench-scale soil washing evaluation.

C.5.4 Test Results

Complete results for all of the procedures conducted under the lead characterization study are detailed in the final reports prepared by Hazen for each of the six samples tested. The reports are entitled "Laboratory and Bench-Scale Studies for Characterizing Lead-Contaminated Soil from DuPont/Weyerhaeuser Remediation Site", (August-October, 1993). The characterization results are summarized in Table C-3, "Summary of Lead-Soil Characterization Test Results"; the results are presented according to the information categories indicated in Section 4.0. An expanded summary of selected results is presented below in the same format as Table C-3, with limited interpretation.

REGULATORY ANALYSIS

The total lead concentrations, as determined by Method 6010 as part of the RCRA Appendix IX metals analysis, ranged from 260 mg/kg to 3,000 mg/kg for the six composite soil samples tested. The TCLP lead analyses results indicate that the soil samples from Areas 7, 18, 36, and 40 (Pulverizer and Glazemill) were not RCRA D008 hazardous, based on the regulatory limit of 5 mg/1. However, the soil sample from the Packhouse area of Area 40 exceeded the RCRA D008 regulatory threshold with a TCLP lead result of 18 mg/l; the corresponding total lead assay for this sample was 3,000 mg/kg.

TCLP analysis for the other metals and organics was also conducted. The results indicate that the Site soil does not exhibit the RCRA toxicity characteristic for any of these constituents.

There were other RCRA Appendix IX metals present, but these were at very low concentrations in all cases (the highest values were in the Packhouse and Pulverizer areas of Area 40, with zinc concentrations up to 2,500 mg/kg and moderate concentrations of copper and barium). No RCRA Appendix IX semi-volatile organics were present in the soil samples from Areas 7 and 40 (Glazemill and Packhouse). Extremely low levels (ppb) of semi-volatiles were present in the samples from Areas 18, 36, and 40 (Pulverizer). The semi-volatile constituents were polynuclear aromatic hydrocarbons (PAHs), which appear to be related to petroleum-based materials previously identified at the Site.

PHYSICAL ANALYSIS

Physical testing determined that the USDA standard soil classification was "sand" for the samples from Areas 7, 36, and 40, and "sandy loam" for the sample from Area 18. The results of the Atterberg Limits tests indicate that all six-soil samples were non-plastic, suggesting that soil excavation and processing can be managed in a straightforward manner.

The particle size distribution test results for the soil samples ranged from 38 to 61% cobbles/gravel (greater than 4 mesh), 32 to 53% sands (less than 4 and greater than 200 mesh), and 7 to 15% silt/clay (less than 200 mesh). This data indicates that the soil is amendable to standard physical screening or size classification-type soil washing treatment.

The moisture content results ranged from approximately 5 to 20%; loose and packed densities ranged from 1.1 to 1.6 grams/cubic centimeter (g/cm3) (or approximately 0.9 to 1.3 tons/cubic yard (tons/yd3)) and from 1.4 to 1.9 g/cm3 (or approximately 1.2 to 1.6 tons/yd3), respectively. The density data is given to represent ex-situ and in-situ soils, respectively, and reflects typical ambient moisture.

The pH of the soil samples ranged from 4.4 to 7.4 in a slurry (10% solids) of soil and demineralized water. Since the soil is mildly acidic to neutral, it will not be corrosive to excavation, materials handling, and other treatment equipment.

The physical analyses data collectively indicate that materials handling of the Site soils, including provisions for dust control should be uncomplicated and accomplished using conventional equipment and methods.

CHEMICAL ANALYSIS

Lead assays performed using Method 7420 on pulverized heads of whole soils for each of the six samples determined total lead concentrations (average of three readings) in the range of 180 to 3,600 mg/kg.

Anions considered likely to produce metal salts of low solubility were investigated in the soil samples. Those found to be present were sulfide, sulfate, phosphate, and carbonates. Total concentrations of these low solubility bonding/binding anions present in the samples from Areas 7, 18, and 36 ranged from approximately 2,500 to 2,650 ppm. The total concentrations of these anions in the samples from Area 40 ranged from approximately 4,200 to 10,700 ppm. In general, the level of anions in the soils is substantially greater (up to 10X) than the total lead concentration, indicating that low solubility metal salts can potentially form. Evidence of such compounds in the soils was provided using more sophisticated speciation techniques, as discussed in later sections.

The presence of soluble cations, which can compete with any soluble lead species for soil adsorption sites, soil ion exchange sites and binding anions, was also screened. Competing cations investigated were calcium, sodium, magnesium and potassium. The total leachable concentration of these cations present in the soil sample from Area 18 was very low at less than 50 ppm. The total leachable concentrations of cations present in the samples from Areas 7, 36, and 40 (Glazemill and Packhouse) were low, ranging from 50 to 100 ppm. The total leachable concentration of cations present in the soil sample from the Pulverizer area of Area 40 was also low at less than 300 ppm. These results indicate that soluble lead should be able to bind with soil at adsorption and ion exchange sites since competition is not severe. The results are consistent with sequential extraction speciation results discussed later.

Organic carbon (organic matter) content is important as it can bind with heavy metals and can potentially interfere with soil treatment processes. The organic carbon present in the soil samples from Areas 7, 18, and 36 ranged from 0.9 to 3.3%; no detectable levels of inorganic (fixed) carbon were reported for these samples. The organic carbon present in the samples from Area 40 ranged from 4.2 to 6.9%; the inorganic carbon content of these samples ranged from non-detect to 0.7%. These levels are considered moderately low from a soil treatment perspective and should not interfere with implementation or performance of soil washing, solidification/stabilization and other technologies. Sequential extraction was used to determine how much lead was associated with organic matter in the soil.

The results of X-Ray Fluorescence analysis (XRF) indicate the presence of a soil matrix comprising silica, alumina and iron oxide, with minor amounts of sodium, magnesium, potassium, phosphorus, sulfur, titanium and calcium. These results are to be expected for the type of soils present at the Site.

The Generalized Acid Neutralization Capacity (GANC), Reverse GANC (RGANC), and pH analyses data indicate that the soil samples ranged from slightly acidic to neutral and had little acidic or basic buffering capacity.

Results of the Sequential Extraction tests performed on selected sized fractions indicate that the majority of the lead was present in carbonate, specifically adsorbed, and in ion-exchangeable forms in samples from Areas 7, 18, and 36. For the Area 40 samples, the majority of the lead was shown to be associated with carbonates, iron and manganese oxides, and organic material.

Speciation analyses performed on selected sized fractions (gravity separated as appropriate) using Scanning Electron Microscopy (SEM) and X-Ray Diffraction (XRD) gave positive identification of lead in the following forms: lead carbonate, lead oxide, lead-iron oxide, lead-manganese oxide, lead-tin oxide, lead-aluminum oxide, lead sulfate, lead sulfide, lead silicates, lead phosphates, and metallic lead.

LEACHING/MOBILITY

The TLCLP lead analytical results are summarized in the Regulatory Analysis section, above.

The Equilibrium Leaching Procedure (ELP) results demonstrate very low lead solubility with synthetic acid rain (0/02 to 0.06 mg/l). The wet screening and Sequential Extraction test results also demonstrate that the lead species are relatively insoluble in water. However, the lead was more soluble in acetic acid solutions, as demonstrated by TCLP, GANC, and Sequential Extraction test data. These results indicate that lead is essentially immobile under normal environmental conditions, but can be mobilized under more rigorous leaching conditions.

Under the GANC and RGANC tests, one stage acidic and alkaline leaching at 20:1 liquid/solids ratio removed a range of 45 to 75% of the lead using 2N (normal) acetic acid, and a range of 13 to 40% of the lead using 2N sodium hydroxide. This indicates that lead is more readily mobilized under acidic, as opposed to basic, leaching conditions, but also indicates the presence of some extremely leach-resistant forms of lead.

SOLIDIFICATION/STABILIZATION SCREENING – UNIVERESITY OF CINCINNATI (CGEST)

Three non-proprietary binding mixes (two containing Portland cement and one containing a combination of cement kiln dust and fly ash) were used to screen solidification/stabilization technology, using -200 mesh fractions of soil samples from Areas 36 and 40 (Glazemill and Pulverizer) supplied to CGEST by Hazen. The following are the main results after 28 days of curing:

- All three design mixes passed TCLP, with lead leachate results ranging from 0.29 to 1.5 mg/l;
- The amount of lead that leached in the TCLP tests ranged from 0.44 to 2.73% of the total lead in the treated sample (initial untreated soil lead concentrations ranged from 2,900 to 3,200 mg/kg);
- The end point pH in the TCLP tests ranged from 5.2 to 8.2; and
- Unconfined Compressive Strength (UCS) data for the prepared samples of fine material with Portland cement binder ranged between 18 and 96 pounds per square inch. The fine material treated with kiln dust/fly ash did not set within the 28-day curing time and strength analysis could not be completed.

BENCH-SCALE SOIL WASHING STUDY – STATE UNIVERSITY OF NEW YORK, BUFFALO (UB)

The Department of Civil Engineering at the UB examined soil leaching through laboratory and bench-scale experiments. The efficacy of various soil leaching extraction agents and conditions was evaluated for removing lead from a lead-impacted soil sample (-8 to +200 mesh fractions) from Area 40 (Pulverizer). The results relevant to the evaluation of treatment technologies are summarized below:

- Soil lead was reduced to less than one-half the initial mean concentration of 1,401 +/- 244 mg/kg (95% confidence interval) in approximately one-third of the soil leaching experiments conducted.
- The lowest soil lead concentration (444 +/- 24 mg/kg) was achieved using hydrochloric acid at a pH of 1 with a liquids/solids ratio of 10:1, and at 25 deg C;
- Strong mineral acid extractants containing the chloride ion (HC1, HC1O4) were the most effective at removing lead from the soil;

- Significant lead removal (>50%) was achieved with an HC1 extraction solution at more moderate pH (~3) with the addition of EDTA as a complexing (chelating) agent; and

- TCLP lead values for the treated soil samples ranged from 0.3 to 0.5 mg/l.

C.5.5 Interpretation of Results

The Hazen soil characterization results which bear most significantly on the viability and effectiveness of solidification/stabilization, physical screening/soil washing, and smelting/thermal recovery technologies for remediating lead-impacted soils are listed in Table C-3. A brief discussion of key results from the characterization study, including implications for technology selection, is provided below. Results of the UB bench-scale soil washing tests and the CGEST solidification/stabilization screening tests are also discussed briefly, as appropriate.

SOLIDIFICATION/STABILIZATION

As indicated in Table 3, the characterization test information most relevant for the evaluation of solidification/stabilization remediation technology are GANC/RGANC, Metals Acid Neutralization Capacity (MANC)/Reverse MANC, organic carbon, RCRA Appendix IX semi-volatiles, TCLP, and moisture content.

As previously mentioned, the GTANC, RGANC, and pH analyses indicate that the Site soils sampled are mildly acidic to neutral and have little acidic or basic buffering capacity. The low buffering capacity is advantageous for a solidification/stabilization process because a minimum amount of binder would need to be added to buffer the soil, add reserve alkalinity, and drive lead solubility to low values. Based on the GASNC and MANC plots, the optimal pH (corresponding with the minimum lead solubility) for the Site soils for solidification/stabilization treatment lies in the range of moderately acidic to moderately basic (pH 4-10).

The carbon analysis results indicate that the organic carbon content in the Site soils (0.9 to 6.9%) is typically below levels (<10%) that would be expected to inhibit curing in a solidification/stabilization process. However, with regard to the stabilization of soil fines (-200 mesh), the CGEST study indicates that fly ash/kiln dust binders require longer curing times than Portland cement binders.

The RCRA Appendix IX semi-volatiles results indicate that semi-volatiles are either absent in the Site soils or present only in very low concentrations. These results indicate the application of a straightforward solidification/stabilization treatment. Some semi-volatile organics (sugars, alcohols) can be difficult to solidify/stabilize and may inhibit curing of treated material.

Only one of the six samples analyzed for TCLP exceeded the RCRA D008 regulatory threshold of 5 mg/l, the Area 40 (Packhouse) soil sample (18 mg/l). No other constituents exceeded TCLP threshold levels. These results indicate that if solidification/stabilization treatment were applied to the Site soils, the TCLP lead leachability criterion would be readily met. The solidification/stabilization screening performed by CGEST further supports this conclusion. Here, several conventional binding mixes were tested on soil fines from Areas 36 and 40 (Glazemill and Pulverizer) and yielded TCLP results well below the 5 mg/l RCRA Land Disposal Restriction (LDR) treatment standard, on the stabilized soils (0.29 to 1.5 mg/l).

The moisture content results for the Site soils were variable, ranging from approximately 5 to 20%. Moisture content is the most sensitive input variable in solidification/stabilization system design and requires careful control during implementation. At the levels measured in this case, based on the CGEST solidification/stabilization screening work where moisture contents were in the range of 40 to 50%, a requirement for make-up water is indicated.

PHYSICAL SCREENING/SOIL WASHING

The characterization test results of most relevance for the evaluation of physical screening/soil washing remediation technologies (as shown in Table C-3) are silt-clay content, lead distribution with regard to

particle size, surface area calculations, Atterberg Limits, organic carbon, GANC/RGANC, MANC/RMANC, and Sequential Extraction.

The silt/clay content of the Site soils, ranging between 7% and 15% for the samples tested, is quite low, and well below the 40% upper limit generally considered likely to limit the effectiveness of soil washing processes. The lead content in the silt/clay fraction of the Site soils is substantial at between 27% and 67% (corresponding concentrations range from 2,170 mg/kg to 10,600 mg/kg). These results suggest that significant beneficial volume reduction of lead-impacted soil could be achieved by separating the fine material from the whole soil.

Wet screen particle size distribution test results and corresponding chemical analyses results for separated size fractions indicate that between 84% and 97% of the soil lead is concentrated in the sand and silt/clay fractions. These fractions represent between 40% and 62% by weight of the whole soil. These results indicate that recovery of the cobbles/gravel fraction (representing between 38% and 60% of the whole soil) as "clean" material could be readily achieved using conventional wet screening or classification-type soil washing.

For water-based soil washing processes, the wet screening and Sequential Extraction test results indicate that, due to the low aqueous solubility of lead in Site soils, little or no water treatment provisions would be necessary.

The surface area calculations for each of the soil size fractions indicate, as expected, that the majority of the total soil surface area is contained in the silt/clay (64% to 83%), with less in the sands (17 to 36A%), and least in the cobbles/gravel (<1% to 2%). In the case of Areas 7 and 18, the lead distribution by size fraction increases with reducing size fraction and increasing surface area; these results indicate that lead bonding and binding is mostly surface related. The lead distribution for Areas 36 and 40 in the sand and silt/clay fractions does not proportionally follow surface area distribution; this indicates that lead is not only surface bound but is also associated with other particulate matter present in the soil matrix. In the case of Area 36 soils, SEM confirmed the presence of particulate lead.

The Atterberg Limits results show that the "sand" and "sandy loam" soil is non-plastic and should be both amenable to processing by physical screening equipment and easy to handle with conventional earth-moving equipment.

The organic carbon content of the Site soils (0.6% to 6.9%) is below the 10% limit generally considered as the value above which complications in a soil washing system can arise due to contaminant-carbon bonding. The inclusion of an organic carbon removal unit operation should not be necessary.

The GANC/RGANC results, as mentioned previously, show that the Site soils have little buffering capacity and would not require the addition of large amounts of acid in a chemically enhanced soil-washing scenario, to achieve a desired pH change.

The MANC/RMANC equilibrium lead concentrations in the aqueous phase occur between additions of 2 to 40 equivalents of acid/kg soil and between additions of 2 to 40 equivalents of base/kg. One stage acidic and alkaline leaching at 20:1 liquids/solids ratio can remove 45% to 75% of the lead using 2N acetic acid, or 13% to 40% lead using 2N sodium hydroxide. This indicates that acidic leaching has potential for use in a soil washing system to clean the Site soils, possibly in conjunction with wet screening and other physical (gravity, density, and high-energy attrition) treatment techniques. It is important to note, however, that even under severe leaching, lead removal is not complete as can be explained by the presence of some extremely leach-resistant forms of lead.

Sequential Extraction data show that lead is predominantly present, in the sized fractions examined, as carbonate, specifically adsorbed, and non-exchangeable forms, as well as being associated with iron and manganese oxides and organic material. This speciation information, which is supported by the SEM and

XRD results, also indicates that further lead removal could be achieved in a chemically enhanced (acidic) soil washing or leaching treatment scenario.

The results of the UB soil washing study provide further support for considering a chemically enhanced soil washing or leaching treatment application. The study showed that strong mineral acid extractants (specifically, hydrochloric and perchloric acid) at approximately pH 1 were effective at significantly reducing (by greater than 60%) lead concentrations of approximately 1,400 mg/kg in the sand fraction of Site soils. TCLP lead values for treated samples ranged from 0.3 to 0.5 mg/l. Less acidic conditions (pH 3) were also effective if a chelating agent (such as EDTA) was added. Other conclusions drawn from this study, such as those relating to the detailed behavior of complexing compounds and the effects of temperature and liquid/solids ratio, as well as aqueous extract treatment/recycling, will be essential issues to consider when deciding on whether to include leaching in a soil washing treatment approach.

SMELTING/THERMAL RECOVERY

The characterization test results of primary importance for the evaluation of smelting/thermal recovery remediation technology are total lead concentrations, moisture content, RCRA F039 listed metals, and soil mineralogy results.

Cost effective treatment of RCRA D008 wastes by smelters requires that lead content in the feed soils be on the order of 6 to 8% by weight or that the soil contain at least 80% silica (silica is a flux agent used in smelting). Since total average lead concentrations in the Site soils lie in a range of only 180 to 3,600 mg/kg (i.e. 0.4% maximum), and even the highest measured concentration in the silt/clay fraction is only 1.1%, the soils would not be suitable for smelting without intensive pre-processing to concentrate lead into the finer soil fractions. Silica content for Site soils ranges from 30 to 60%, which also indicates that the soil is not suitable as a silica flux replacement in smelting. Though the possibility of using smelting to treat concentrated soil-washing residuals does still exist, the technical and economic viability would require further investigation.

The maximum acceptable moisture content of a smelter feed soil is 10%. This may place a further constraint on the smelting application for the Site soils; concentrated fines/residuals from a soil washing process would likely need to be passed through an advanced dewatering step.

The RCRA F039 metals analyses indicate the present of other metals including: antimony, arsenic, barium, chromium, copper, nickel, selenium, vanadium, and zinc. Though present at low concentrations, these metals are potential impurities in certain smelter products that may restrict the facilities that could potentially handle the soils or treatment residuals.

The XRF analysis results indicate the presence of a silica-alumina-iron oxide matrix, with minor amounts of sodium, magnesium, potassium, phosphorus, sulfur, titanium, and calcium. The presence of these elements is expected in sandy and silty soils. They could, however, adversely affect the viability of smelting/thermal recovery as impurities in the system.

C.5.6 Arsenic-Impacted Soils

Soil samples for the Hazen study were collected from each of the following areas of the Site (one sample per area): Area 18, Area 36, and the Narrow Gage Railroad area. In addition to the characterization work performed by Hazen, Hart Crowser performed a laboratory wet screening study to better define the concentration distribution in relation to soil particle size on samples from these same areas. An additional five soil samples from the 250/500-foot arsenic sampling grid area (including Areas 18 and 36), and five samples from the Narrow Gage Railroad area were collected for the Hart Crowser study. The sample collection methods are summarized in the following paragraphs.

Previous sampling results were used as a basis for establishing sampling grids in each area. For the Area 18 and 36 grids, a random number generator was used to select 25 discrete sample locations. Some parts of the Site, within targeted areas, shown by previous sampling results to exhibit arsenic

concentrations below the Site background level of 32 mg/kg were not included in the sampling regime. The Narrow Gage area was segregated into 100 linear segments along the railroad track; 25 segments were randomly selected for collection of three-point composite samples, which were composited into a 55-gallon sample. For the Hart Crowser screening study, ten five-point composite samples were collected at locations identified during the RI (including the December 1993, Phase I Arsenic Sampling) as areas of elevated arsenic.

The soil samples for each grid area were taken from a shallow depth interval (0-1 foot) chosen to represent the soil to be potentially remediated based on previous vertical delineation. Composite sampling was chosen to adequately represent each area because the resulting soil homogenization is a simulation of the mixing that would occur under full-scale excavation and ex-situ treatment operations. Arsenic concentration variability issues will be more specifically addressed in any future pilot testing.

Approximately two gallons of soil were collected from each of the 25 selected sampling locations for the Hazen study. The 25 samples were then composited into one representative 50-gallon sample for each area and shipped to Hazen in 55-gallon drums. Upon receipt of the soil samples, Hazen personnel prepared and tested the samples. Portions of the samples from Area 18 and the Narrow Gage Railroad area were sent to Weyerhaeuser ATS for the bench-scale soil leaching study.

C.5.7 Test Results

Complete results for all the procedures conducted under the arsenic characterization study are detailed in the final report prepared by Hazen for each of the three samples tested. The reports are entitled "Laboratory and Bench-Scale Chacterization Studies for Arsenic-Contaminated Soil from DuPont/Weyerhaeuser Remediation Site," (March-April, 1994). The characterization results are summarized in Table 4, "Summary of Arsenic-Soil Characterization Test Results". The results are presented according to the information categories indicated in Section 4.0. An expanded summary of selected results is presented in the following sections, with limited interpretation. Further data interpretation, as applicable to specific remediation technology categories, is provided in Section 5.4.2.

REGULATORY ANALYSIS

The TCLP arsenic analyses results for each of the soil samples were less than 0.07 mg/l and indicate that the samples were not RCRA D004 hazardous, based on the regulatory limit of 5 mg/l. TCLP analysis for the other metals and organics was also conducted on the sample from Area 36; the results indicate that the soil does not exhibit the RCRA hazardous toxicity characteristic for any of these constituents.

PHYSICAL ANALYSIS

Physical testing determined that the USDA standard soil classification was "sand" for the soil samples from each of the three Areas. The results of the Atterberg Limits tests indicate that the samples from Areas 36 and 18 (by inference from analysis performed on a different composite sample from Area 18) were non-plastic.

The particle size distribution test results for the soil samples ranged from 52% to 66% cobbles/gravel, 26 to 39% sands, and 8 to 10% silt/clay.

For the Area 36 sample, the moisture content measured 5% and the loose and packed densities measured 1.6 and 1.9 g/cm3 (or approximately 1.3 and 1.6 tons/yd3), respectively. Also, the pH of a soil slurry measured 6.3, which indicates that the soil will not be corrosive to excavation, materials handling, or other treatment equipment.

Many of the physical analyses performed on the lead samples were not considered necessary when studying arsenic-impacted soils because much of the general information gathered from the lead characterization/treatability studies could be applied to soils across the Site for the purposes of evaluating potential treatment technologies. The physical analyses data collectively indicate that materials handling of the Site soils will not be complicated.

CHEMICAL ANALYSIS

Arsenic assays performed using Method 7060 on pulverized heads of whole soils for each of the three samples tested determined total arsenic concentrations in the range of 29 to 353 mg/kg.
Concentrations of low solubility bonding/binding anions and soluble cations, and organic carbon content for the Area 36 sample were measured at 2,640 ppm, 77 ppm, and 0.9%, respectively as reported under the lead characterization study. Although these analyses were not performed on the Area 18 sample, existing data from the lead characterization study composite sample from Area 18 indicates that the soils from Areas 18 and 36 have similar chemical characteristics.

The XRF analyses data indicate the presence of a silica=alumina-iron matrix with lesser amounts of sodium, magnesium, potassium, and calcium. These results are to be expected for the type of soils present at the Site and are consistent with the results from the lead characterization study.

The GANC/RGANC and pH analyses data show that the soil samples were essentially neutral and had no appreciable acidic or basic buffering capacity.

Sequential Extraction test results for selected sized fractions indicate that, for all samples, the occurrence of arsenic in the selected sized fractions examined was mostly in association with iron oxides and the organic portion of the soils.

Speciation analyses performed on selected sized fractions (gravity separated as appropriate) using SEM confirmed and Sequential Extraction test results that arsenic as associated with iron oxides and with the organic portion of the soil. SEM also gave positive identification of arsenic in the following forms or associations: iron-arsenic-phosphate, potassium-iron-sulfate, silicates, manganese oxides, and lead-arsenic-sulfate. An overall assessment of the SEM results suggests that arsenic exists predominantly in the +5 valence state.

LEACHING/MOBILITY

The TCLP arsenic analytical results are summarized in the Regulatory Analysis section, above.

Under the GANC and RGANC tests, one stage acidic/basic leaching at 20:1 liquids/solids ratio removed a range of two to four percent of the arsenic using 2N (normal) acetic acid, and 74% to 80% using 2N sodium hydroxide, respectively. This indicates that arsenic is more readily mobilized under basic, rather than acidic, leaching conditions. In general, the solubility of arsenic in the RGANC test was ten times higher than the corresponding solubility in the GANC test. This can be explained by reference to the sequential extraction results, which indicate the predominant arsenic forms and associations identified in the Site soils. Arsenic compounds in the +5 valence state are soluble under oxidizing conditions and at high pH.

The arsenic was more soluble in weak sodium hydroxide solutions than under moderate acetic acid leaching conditions, as demonstrated by TCLP, GANC, and Sequential Extraction test data. These results indicate that arsenic is essentially insoluble and immobile under normal environmental conditions, but can be mobilized under more rigorous high pH (caustic) leaching conditions.

BENCH-SCALE SOIL LEACHING STUDY – WEYERHAEUSER ATS

The potential of solutions of sodium hydroxide and sodium carbonate (at varying strengths, with and without phosphate addition) to extract arsenic from -1/4" to +200m fractions of the Site soil were investigated in single-stage batch extraction experiments under a study performed by Weyerhaeuser ATS. The effect of changes in liquid/solids ratio was evaluated, and the relative leaching efficiencies achieved for several sub-fractions of the soil sample examined. A simulation of a potential multi-stage countercurrent field extraction process was also conducted. The principal finds of this study are as follows:

- Soil arsenic concentrations were reduced by a maximum of 57% from a starting concentration of between 103 and 113 mg/kg in a single-stage batch extraction at an end point pH of 11.5 with 0.02 N sodium hydroxide and a liquid/solids ratio of 20:1. Similar performance was achieved with a sodium carbonate solution, although asignificantly higher reagent dose (e.g. 0.33 N) was necessary.

- A phosphate solution at near neutral pH was able to reduce arsenic concentrations by up to 10%. Extraction efficiencies of up to 25% were achieved in experiments evaluating the performance of phosphate in conjunction with alkali; appreciable pH buffering by phosphate was, however, seen, particularly in solutions including sodium carbonate.

- Leaching performance was shown to vary as a function of end point pH under the extraction experiments (increased sharply with increasing pH over the range of reagent strengths tested).

- Caustic leaching performance was not constrained by arsenic solubility under tests involving liquid/solids ratios of between 5:1 and 20:1.

- A somewhat greater percentage reduction in soil arsenic concentration was seen for the larger sub-fraction in a single-stage batch extraction examining relative leaching efficiencies for three sub-fractions of the tested soil.

- The overall leaching performances achieved under single stage batch and simulated multi-stage countercurrent extractions were comparable.

WET SCREENING TESTING – HART CROWSER

A total of five composite soil samples from the 250/500-foot arsenic sampling grid area and five samples from the Narrow Gage Railroad area were taken for wet screening analysis. The analysis involved separation of the whole soil into a series of size fractions for subsequent total arsenic analysis. The data generated were combined with the wet screening data derived for arsenic-impacted soil samples from Area 18, Area 36 and the Narrow Gage Railroad area under the Hazen study, the presence of higher arsenic concentrations in the smaller size fractions was consistently shown by these results. The combined results were subjected to a statistical evaluation (involving calculation of cumulative mean arsenic concentrations with reducing size fraction) to allow various “cut points” to be examined in consideration of potential remediation scenarios featuring soil size separation.

SPECIATION ANALYSIS – BATTELLE PACIFIC

Data from the Battelle Pacific speciation study indicate that, in the areas of the Site sampled (Areas 5, 25, 38, and Narrow Gage Railroad), arsenic is largely present as As(V). As(III), the common reduced form, accounts for less than one percent of the total soil arsenic. One sample in the Narrow Gage Railroad area contained about four percent organic (methylated) arsenic, which indicates the possible use of organic arsenic-based herbicides on the Site.

SOLIDIFICATION/STABILIZATION SCREENING – UNIVERSITY OF CINCINNATI (CGEST)

Three non-proprietary binding mixes (two featuring Portland cement and one featuring a combination of cement kiln dust and fly ash) were used to stabilize the -200-mesh fraction of a soil sample from Area 36 supplied to the University by Hazen. The initial arsenic concentration in the soil fraction was 205 mg/kg. All three design mixes passed TCLP following a 28-day curing period, with arsenic leachate results below the method detection limit (<0.1 mg/l).

C.5.8 Interpretation Results

The soil characterization results which bear most significantly on the viability and effectiveness of solidification/stabilization, physical screening/soil washing, and smelting/thermal recovery technologies for remediating arsenic-impacted soils are listed in Table C-2. A brief discussion of key results from the

characterization study, including implications for technology selection, is provided in the following sections. The results of the CGEST solidification/stabilization screening tests, the Hart Crowser wet screening testing, and the Weyerhaeuser ATS bench-scale soil leaching study are also discussed briefly, where appropriate.

SOLIDIFICATION/STABILIZATION

The characterization test information most relevant for the evaluation of solidification/stabilization remediation technology are GANC/RGANC, organic carbon, RCRA Appendix IX semi-volatiles, TCLP (inorganic and semi-volatiles), and moisture content.

As previously mentioned, the GANC/RGANC and pH analyses indicate that the Site soils sampled are neutral and have essentially no acid or basic buffering capacity. The low buffering capacity is advantageous for a solidification/stabilization process because it minimizes the amount of solidification/stabilization binder that would need to be added to buffer the soil and maintain the arsenic solubility at low values. Based on the GANC and RGANC plots only, the optimal pH for the Site soils (corresponding to minimum solubility) for solidification/stabilization treatment of arsenic is in the acidic range (pH 3 to 4). This is consistent with the speciation results since As(V) species are known to be very insoluble in acid. To ensure a practical treatment and sensible pH conditions, the target end point pH under TCLP testing should be only a slightly acidic pH 5 to 7.

The carbon analysis results indicate that the organic carbon content in the Area 36 Site soils (<1%), which is a measure of the soil's natural ability to bond and bind with arsenic and other constituents, is typically below levels (<10%) that would be expected to inhibit curing in a solidification/stabilization process. With regard to the stabilization of soil fines (-200 mesh), the CGEST study indicates that fly ash/kiln dust binders require longer curing times than Portland cement binders.

The RCRA Appendix IX semi-volatile organics results (produced for the Area 36 soil sample) indicate that semi-volatiles are either absent in the Site soils or present only in low concentrations. These results support the application of solidification/stabilization treatment since semi-volatiles can be difficult to stabilize/solidify and may inhibit curing of the treated material.

None of the TCLP results exceeded the RCRA D004 regulatory threshold of 5 mg/l and no other constituents exceed TCLP threshold levels. These results indicate that if solidification/stabilization were to be applied to the Site soils, the TCLP arsenic leachability criterion would be readily met. The solidification/stabilization screening performed by CGEST further supports this conclusion. Here, several conventional binding mixes were tested on soil fines (-200 mesh) from Area 36 and yielded TCLP results well below the 5 mg/l RCRA LDR treatment standard on the stabilized soils (measured levels were less than the method detection limit, 0.1 mg/l). It is important to note that the Area 36 soils analyzed in the CGEST study were also impacted with lead. Typically, lead stabilization requires alkaline conditions, while arsenic stabilization is best performed under more neutral to slightly acidic conditions. For the binders tested, the study showed that a slightly alkaline "balance" can be struck (end point pH's in the range 5.2 to 8.2 under TCLP testing) that will stabilize lead and also will not leach excessive arsenic. This is an important finding, warranting further consideration in the event that fines generated from a soil washing system campaigning a mixture of lead- and arsenic-impacted soils require further solidification/stabilization treatment.

The moisture content results for the Site soils were fairly variable, ranging form approximately 5% to 10% for Area 18 (by inference from results for the lead characterization study sample from the same Area) and Area 36. Moisture content is the most sensitive input variable in solidification/stabilization system design and requires careful control during implementation. At the levels measured in this case, based on the CGEST solidification/stabilization screening work where moisture contents were in the range of 40% to 50%, a requirement for make-up water is indicated.

PHYSICAL SCREENING/SOIL WASHING

The characterization test results of most relevance for the evaluation of physical screening/soil washing remediation technologies are silt/clay content, arsenic distribution with regard to particle size, surface area calculations, Atterberg Limits, organic carbon, GANC/RGANC, MANC/RMANC, and Sequential Extraction.

The silt/clay content of the Site soils, ranging between eight and ten percent for the samples tested, is well below the 40% limited generally considered likely to limit the effectiveness of soil washing processes. The arsenic content in the silt/clay fraction of the soils is substantial at between 51% to 71% (corresponding concentrations range between 186 and 2,550 mg/kg) and suggests that significant beneficial volume reduction of arsenic-impacted soil could be achieved by separating the fine material from the whole soil.

Particle size distribution test results and corresponding chemical results for separated size fractions under the Hazen and Hart Crowser wet screening studies indicate that between approximately 79% and 92% of the soil arsenic is concentrated in the sand and silt/clay fractions. These fractions represent between 27% and 56% of the whole soil. These results indicate that recovery of the cobbles and gravel fraction (representing between 44% and 73% of the whole soil) as "clean" material could be readily achieved using conventional wet screening or classification-type soil washing.

For water-based soil washing processes, the wet screening and Sequential Extraction test results indicate that, due to the low aqueous solubility of arsenic in Site soils under near-neutral pH conditions, little or no water treatment provisions would be necessary.

The surface area calculations for each of the soil size fractions of the Area 36 sample show, as expected, that the majority of the total soil surface area is contained in the silt/lay (~80%), with less in the sands (~20%), and least in the cobbles/gravel (<2%). The arsenic distribution by size fraction for the Area 36 sample increases with reducing size fraction and increasing surface area; these results indicate that arsenic bonding and binding is mostly surface related.

The Atterberg Limits results for the Area 36 soil sample show (as seen generally for all other Site samples tested) that the "sand" soil is non-plastic and should be amenable to processing by physical screening equipment and easy to handle by conventional earth-moving equipment.

The organic carbon content of the Area 36 soils is 0.9%, significantly below the 10% limit generally considered as the value above which complications in a soil Washington system can arise due to contaminant/carbon bonding. Although organic carbon data for the other arsenic characterization soil samples are not available, information from the lead characterization study (Section 5.3) indicates that the organic content of soils across the Site does not vary significantly. The inclusion of an organic matter removal unit operation in a soil washing process to address soil organic carbon should not be necessary.

The GANC/RGANC results show that the Site soils have little buffering capacity and will not require the addition of large amounts of base in a soil-washing scenario to achieve a desired pH change.

In the consideration of MANC/RMANC equilibrium arsenic concentrations, high acetic acid concentrations (approximately 14 equivalents of acid/kg soil) were required to leach arsenic, whereas RGANC indicated that about two base equivalents/kg soil were required for optimum leaching. One stage acidic/alkaline leaching at 20:1 liquids/solids ratio can remove two to four percent of the arsenic using 2N acetic acid, but amounts of between 74% and 80% can be removed using 2N sodium hydroxide. These results indicate that chemical leaching using alkaline reagents has potential for use in a soil washing process to clean the Site soils, possibly in conjunction with wet screening and other physical treatment techniques. Conversely, mildly acidic conditions might be employed in a soil washing treatment scenario to ensure that arsenic remains concentrated in the fines fraction, which could subsequently be stabilized.

Sequential Extraction data show that arsenic is predominantly present, in the sized fractions examined, in association with iron and manganese oxides and organic material. The results indicate that arsenic

species are not soluble in water or under acidic conditions, but can be solubilized under caustic conditions (the organic matter sequential extraction step uses sodium hydroxide and phosphate as the leachant). This speciation information supports the conclusion that chemically enhanced (basic) soil washing or leaching treatment could be used to liberate arsenic from the soils.

The results of the Weyerhaeuser ATS leaching study corroborate the leaching data generated under the Hazen study, and further demonstrate the potential for a chemically enhanced soil washing application, in that they show alkaline solutions to be effective in removing arsenic from the Site soils. In single-stage batch extractions, solutions of sodium hydroxide at approximately pH 11.5 removed up to 57% of arsenic from sand fractions containing starting concentrations of around 100 mg/kg; sodium carbonate solutions gave similar results but required significantly higher reagent doses. A strong dependency on pH was shown in the leaching experiments and there was no evidence that leaching performance was constrained by arsenic solubility. A batch extraction examining relative leaching efficiencies between sub-fractions of the tested soil showed a somewhat greater performance for the larger sub-fraction, and no significant improvements in overall leaching performance were seen in simulated multi-stage countercurrent tests. These various issues will require further investigation before decisions can be made for including leaching in a soil washing treatment application. Similarly, issues including solids hold-up times, temperature and aqueous extract treatment/recycling will need to be addressed.

SMELTING/THERMAL RECOVERY

The characterization test results of chief importance for the evaluation of smelting/thermal recovery remediation technology are total arsenic concentrations, moisture content, RCRA F039 listed metals, and soil mineralogy results.

Cost effective treatment of RCRA D004 waste by secondary smelters requires that arsenic content in the feed soil be on the order of that for lead recovery, i.e., 6-8% by weight. Since total average arsenic concentrations in the Site soils lie in a range of only 29 to 353 mg/kg (i.e., 0.035% maximum), and even the highest measured concentration in the silt/clay fraction is only 0.25%, the soils would not be suitable for smelting without intensive pre-processing to concentrate arsenic into the finer soil fractions. Because of the relatively low arsenic concentrations, the likelihood that smelting would be suitable to treat concentrated soil washing residuals is low.

The maximum acceptable moisture content of a smelter feed soil is 10%. This may place a further constraint on the smelting application for the Site soils; concentrated fines/residuals from a soil washing process would probably need to be passed through a dewatering step.

The RCRA F039 listed metals analyses indicate the presence of antimony, barium, chromium, copper, nickel, selenium, vanadium, zinc, and lead. Though present at low concentrations, these metals are potential impurities, which could adversely impact smelting/thermal recovery processes.

The XRF analysis indicates the presence of a silica-alumina-iron oxide matrix with minor amounts of sodium, magnesium, potassium, phosphorus, sulfur, titanium, and calcium. The presence of these elements is expected in sandy and silty soils. They could, however, adversely affect the viability of smelting/thermal recovery as impurities in the system.

APPENDIX D – *ARSENIC WET SCREENING STUDY*

D.1 Objective and Overview

The objective of performing additional arsenic treatability studies was to better define the distribution of arsenic concentration relative to soil particle size. Distribution data can be used to select a particle size "cut point" for remedial action that corresponds to the cleanup or remediation level for arsenic.

We analyzed soil samples from two areas of the Site, the Narrow Gage Railroad (NGRR) and the 250/500-foot arsenic soil sampling grid (Grid), to determine if the differences in average arsenic concentration are likely to impact the distribution with grain size. We combined the results of the Hart Crowser arsenic treatability studies with the previously performed Hazen arsenic treatability studies to determine the average arsenic concentration associated with different grain sizes.

A total of three Hazen arsenic study analyses were included in this evaluation. Hazen arsenic study results from the Area 36 - Melt Shop and the Area 18 - Hot Spot were incorporated in the evaluation of the Grid soil data. Hazen arsenic study results from the NGRR area were incorporated in the evaluation of the NGRR soil data.

Hart Crowser samples were collected close to locations identified during the RI sampling as areas of elevated arsenic concentrations. The RI sampling concentrations for the Grid and the NGRR, as well as concentrations for the whole sample and the pulverized whole sample from the treatability study, are presented in Table D-1.

The whole sample result represents the analysis of an aliquot of soil from the treatability study samples collected and analyzed using the same procedure used for the RI samples.

The pulverized whole sample result is the concentration in an aliquot of soil from the treatability study following pulverization of the entire soil sample.

D.2 Treatability Sample Collection

A total of ten 5-point composite samples were collected at selected locations that were previously sampled during the RI. Five samples were collected from the NGRR locations to provide samples that contained relatively high concentrations (400 to 950 mg/kg) of arsenic. The remaining five samples were collected from the 250/500-foot RI sampling grid; these were intended to provide treatability study samples containing lower arsenic concentrations (82 to 360 mg/kg). The ten samples were collected using the same procedure. A four-gallon sample was collected from a depth of 0 to 6 inches at each sampling location, using the same sampling procedure as for RI sample collection. Each 5-point composite sample was collected immediately adjacent to the previously sampled RI location. The sample was placed into a clean/lined bucket and appropriately labeled with the same RI sample number as used previously. Table D-1 summarizes the results from the treatability study sample locations and the associated total arsenic concentrations from previous RI analyses.

Several observations can be made by comparison of these data:

- The RI sample results have generally higher arsenic concentrations compared to the treatability study whole sample results.

- The results for the pulverized whole samples are all lower than the results of the non-pulverized whole sample. These results indicate that the higher concentration of arsenic is confined to smaller soil size fractions.

D.3 Treatability Study Procedure

The ten samples were analyzed using the same physical and chemical testing procedures. Physical testing of the samples was performed in the Hart Crowser Physical Laboratory. Chemical analysis for total arsenic was performed at Analytical Technologies, Inc. (ATI) in Renton.

D.3.1 Physical Testing

The following sample preparation and physical testing procedures were performed prior to the total arsenic analysis. Figure D-1 presents a schematic flow diagram of the procedure:

1) Initially, the entire 4-gallon sample was thoroughly mixed to improve homogeneity.

2) The sample was coned and quartered into four portions (approximately 1-gallon each). Three of the quarters were combined into one 3-gallon sieve sample.

3) A 4-oz sample aliquot was collected from the remaining 1-gallon sample and analyzed the aliquot for total arsenic at ATI. This sample is identified as a "whole sample". The remainder of this sample was crushed and pulverized until 50 percent of the sample passed the 100 mesh sieve. A 4-oz aliquot was collected from the pulverized sample and submitted for total arsenic analysis at ATI. This sample is identified as "pulverized whole sample."

4) The whole sample from Step 3 was dried, crushed, and pulverized to 50% passing the 100 mesh sieve.

5) A 4-oz aliquot of the material from Step 4 was collected and submitted to ATI for total arsenic analysis.

6) The 3-gallon sample was dry screened at 10 mesh.

7) The +10 mesh material from Step 6 was wet screened at 10 mesh (-10 mesh to Step 12).

8) The +10 mesh material from Step 7 was dried and sieved with screen sizes of 1", 1/2", 1/4" and 8 mesh.

9) The material retained was then weighed on the 1", 1/2", 1/4" and 8 mesh screens and calculated the >8 mesh percent.

10) After screening and weighing the dried +10 mesh material through 1", 1/2", 1/4", and 8 mesh sieves (Steps 4 and 7) the material retained on each sieve was pulverized so 50 percent of the material was <100 mesh. A 4-oz sample of the pulverized material was collected and sent to ATI for total arsenic analysis.

11) A 4-oz aliquot of each sample was collected and sent to ATI for total arsenic analysis.

12) The -10 mesh material from the wet screening and the -10 mesh from the initial dry screening were combined and dried.

13) The -10 mesh material was weighed for the >8 mesh percent calculation.

14) The -10 mesh material was homogenized and quartered, to produce one 1,000 gram sample aliquot. The remaining sample was held in the original sample container.

15) The 1,000 gram aliquot was wet screened at 200 mesh. (The -200 mesh water and slimes to Step 18). Two samples of the slime water were collected and analyzed for total arsenic (RR-545 and RR-528).

16) The dry +200 mesh material was weighed and then sieved through 16, 30, 60, 100, and 200 mesh sieves.

17) The material retained on these sieves was weighed and the <8 mesh percent was calculated.

18) The material retained on each sieve was pulverized so that at least 50 percent of the sample was <100 mesh. A 4-oz sample of the pulverized material was collected and sent to ATI for total arsenic analysis.

19) A sample of water and slimes from Step 15 was submitted to ATI for total arsenic analysis.

20) The -200 mesh water and slimes from Step 15 were dried and combined the -200 mesh material from Step 15 with the -200 mesh material from Step 16.

21) The dried -200 mesh material was weighed and sampled for total arsenic analysis at ATI.

The above procedures were followed for each of the samples. However, in two cases, modifications occurred during the analysis as noted below.

- Step 18 was not implemented as described above for sample RR-546. The temperature in the oven used to dry the -200 mesh samples from Step 13 was inadvertently increased to 430°C. Typical oven temperatures were approximately 80°C. The higher temperature may have reduced the total arsenic concentration in the sample because of the sublimation of the arsenic from the soil. As a result the -200 mesh material from sample RR-546 from Step 15 was sampled for analysis at ATI. This result will probably be more representative of the -200 mesh material.

- The +8 mesh material was coned and quartered following crushing and prior to pulverizing in order to expedite sample submittal to the lab for analysis. This resulted in about 250 grams of material being pulverized. Large samples of the -8 mesh material were also coned and quartered prior to pulverizing to expedite sample submittal. The reduction of sample size during this process should not impact the analytical result obtained for the particular sieve size because the soil is more uniform following crushing and splitting of the sample and is likely to include equal ratios of each grain size.

D.3.2 Chemical Testing

A total of 130 soil samples were submitted to ATI for total arsenic analysis. Since each sample was dried prior to screening and collecting the sample, the analytical results were reported on a wet weight basis. The differences between the treatability study and RI laboratory methods were compared. The treatability study and RI samples were prepared using SW-846 Method 3050 and, according to the QAPP in the Site Management Plan, analyzed by graphite furnace/atomic absorption (SW-846 Method 7060). This is a similar method used by ATI for all RI arsenic analyses. This is not the method used for the treatability studies performed by Hazen Research. Hazen used an American Society for Testing of Materials (ASTM) Method D 4606-86 which used a slightly more rigorous extraction procedure than was used by ATI. This may have resulted in the Hazen method extracting different amounts of arsenic from each soil sample relative to the amount extracted from a similar sample analyzed at ATI. Hazen used a hydride atomic absorption analysis method different from the graphite furnace analysis method used by ATI. We are unable to predict the impact that these differences may have on the analytical results without a detailed evaluation of these two analytical methods.

Two water samples were submitted to ATI for total arsenic analysis to determine potential dissolution of arsenic during the wet screening process. Samples were analyzed using SW-846 Method 7060, the same analytical procedure used when analyzing the soil samples.

D.3.3 Treatability Study Results

The results of the physical and chemical analysis for the Grid and NGRR soils are presented in Attachment D-1. Table D-2 presents the mean arsenic distribution and cumulative mean arsenic distribution with respect to grain size for both grid samples and railroad samples. A total of 7 samples (2 Hazen, 5 Hart Crowser) were analyzed to assess the arsenic distribution with respect to grain size in grid soil.

Grid Soil: Evaluation of the data generated during the analysis of grid soil is summarized below.

- For the 7 samples analyzed, the average grain size distribution was 60.7% Gravel, 32.0% Sand, and 7.3% Silt. The mean arsenic concentration for each grain size is presented in Table D-2. Based on the data for all of the grid soil samples presented in Attachment D-1, the range of arsenic distribution by soil type is presented below.

Size Fraction	Range of Total Arsenic Distribution in %
+1/4-inch (gravel)	8.4 to 21.4
-1/4-inch to +200 mesh (sand)	28.4 to 55.7
-200 mesh (silt)	22.9 to 47.0

- The calculated pulverized whole sample arsenic concentration and the result for the pulverized whole sample analysis was compared for each sample (see Attachment D-1). The percent difference of these concentrations ranged from +50 percent (Area 18 - Hazen Sample) to -20.0 percent (18R-461). This level of accuracy is attributed to the high degree of variation expected with the high concentrations of arsenic in the matrix.

Narrow Gage Railroad (NGRR) Soil: Evaluation of the data generated during the analysis of NGRR soil are summarized below. A total of 6 samples (1 Hazen, 5 Hart Crowser) were analyzed to assess the arsenic distribution with respect to grain size in NGRR soil.

- For the 6 samples analyzed the average grain size distribution was 57% Gravel, 36.7% Sand, and 6.3% Silt. The mean arsenic concentration for each grain size is presented in Table D-2. Based on the data for the NGRR soil samples presented in Attachment D-1, the range of arsenic distribution by soil type is presented below.

Size Fraction	Range of Total Arsenic Distribution in %
+1/4-inch (gravel)	7.1 to 12.7
-1/4-inch to +200 mesh (sand)	22.0 to 70.7
-200 mesh (silt)	17.4 to 62.8

- The calculated pulverized whole sample arsenic concentration and the result of the pulverized whole sample analysis was compared for each sample (Attachment A). The percent difference of these concentrations ranged from +83 percent (RR-545) to -13 percent (RR-528). This level of accuracy is attributed to the high degree of variation expected with the high concentrations of arsenic in the matrix.

D.3.4 Conclusion

The application of soil washing may be effective when applied to Site soil impacted by arsenic. This treatability study shows that a coarser low concentration fraction and a finer high concentration fraction can be readily attained. The determination of the particle size "cut point" for impacted soils is likely to vary

with the initial concentration of the feed soil. A lower "cut point" may be attained by implementing higher energy particle separation technologies, such as attrition scrubbing.

APPENDIX E – *RANKING OF ALTERNATIVES*

Chapter 6 defines the performance of the alternatives against the alternatives screening criteria (effectiveness, implementability, and cost). Ranking of these alternatives using these criteria was conducted. All members of the FS project team independently ranked the alternatives and the results were compiled into a single ranking for each alternative. A semi-quantitative comparative method was adopted whereby each participant gave each alternative a score of "-2" for very poor "-1" for poor, "0" for average, "+1" for good or "+2" for very good performance according to a given criterion. The score of each participant was normalized to bring each person's average criterion ranking to "0" prior to compiling the results into a single ranking for each alternative and criterion. The comparative analysis allows the evaluation of all the alternatives against the single screening criterion. This allows the ranking mechanism to be used to assess the best and least favorable alternative for the particular criterion. Table E-1 summarizes the compiled results using weighting factors that place equal emphasis on each effectiveness criterion, implementability, and cost.

Different weighting factors were applied to the three screening criteria to examine the sensitivity of the ranking results as preference is given to different screening criteria. Four different weighting factor scenarios were applied to the alternatives to assess relative performance. These four scenarios emphasize the following criteria preferences.

- **Equal:** Effectiveness, implementability, and cost carry the same weight.
- **Favoring Cost:** Effectiveness and implementability are the same weight while cost carries twice the weight.
- **Favoring Effectiveness:** Implementability and cost have the same weight while effectiveness has five times the weight.
- **Favoring Effectiveness and Cost:** Effectiveness carries a total weight of five, one for each sub-criterion, cost carries a weight of three, and implementability carry a weight of two.

The sensitivity of ranking results to the weighting factor set used is presented in Table E-2.

The weighting of the screening criteria had a small effect on the overall ranking of the alternatives. The alternatives were close in each case and the highest ranked alternatives ranked high following the application of different weightings. The ranking of alternatives did not directly influence the selection of alternatives for further analysis. The ranking was performed as a preliminary step in the screening process and was only used as guidance. Table E-3 illustrates this point.

Table E-1 - Screening of Alternatives

APPENDIX F – *COST ESTIMATE FOR REMEDIAL ALTERNATIVES ANALYZED IN DETAIL*

This appendix describes the procedures used in estimating capital costs. The estimating process generally follows the guidance provided by EPA for CERCLA sites, *Remedial Action Costing Procedures Manual*, although the Site is not being administered under the EPA CERCLA process. This guidance was selected as being appropriate because of the number of constituents identified during the RI.

F.1 Capital Cost

Capital costs are those costs that are incurred during the construction and implementation of the cleanup action. These include: unit price for each process element (e.g., excavation, treatment, disposal); engineering design; contingency allowance; construction oversight; administration; and community relations. Direct and indirect capital costs were developed separately since several of the indirect costs are estimated as a percentage of the direct costs.

F.1.1 Direct Capital Costs

The direct capital costs include estimates of the construction, implementation, and disposal costs. These costs were gathered from vendors who provided budgetary estimates based on specific Site information generated from the RI and the treatability studies. In general, the vendors responded with a range of costs that may be applicable for the remedial action of Site soils. The average low and high vendor unit cost estimates are presented in Table F-1. The variability between the low and high cost was expected since the vendors were not asked to provide a bid for services, which in many cases would require a pilot study or bench-scale treatability studies on Site soils.

Using the unit costs presented in Table F-1, estimated costs were assembled by summing the unit costs for each activity that are combined to comprise each alternative. Table F-2 presents an activity-by-activity cost estimate and a low and high total and overall direct costs for each of the alternatives analyzed in detail in Section 6.0. These estimates of remedial action cost are assumed to be accurate to within -30 percent and +30 percent of the estimate where both estimates could vary by –30 to +30 percent of the listed value. In effect, the estimated "Best Estimate" remedial action cost would be defined as average of the high and low estimate.

Several assumptions, listed below, were necessary to complete the direct capital cost estimates:

- Estimate of soil volumes is based on RI and ISR data, which are assumed to be accurate and complete;
- Cleanup or remediation levels for all constituents are assumed;
- Estimate of soil volumes was conducted according to the procedures and assumptions described in Section 3.0, and are the basis for the direct cleanup action costs; and
- Direct costs are based on the technology unit costs developed from vendor solicitation, engineering estimation, treatability study results, and past experience with similar technologies.

EPA guidance also recommends that the direct cost estimates include the estimated costs for equipment, land and site development needed to implement the cleanup action, buildings and services, and relocation costs. These costs were not included in the estimated direct cost for the following reasons:

- **Equipment**. At this time we anticipate that the remedial action will be done as by a contractor to Weyerhaeuser or DuPont. Subsequently, the cost for the purchase of equipment will likely be small in relation to the total cleanup action cost.

- **Land and Site Development**. Expenses associated with the preparation of the Site prior to implementing the remedial action are likely to be small in relation to the total cleanup action cost.

- **Buildings and Services Cost**. Buildings used by the contractors during interim source removal will again be utilized by the remedial action contractor, and no new facilities are anticipated. Services including electricity, garbage, sewer, and other utilities, which are not included in the unit cost of the remedial alternative, will be small in relation to the total action cost. The unit costs presented in Table F-1 are assumed to include the costs associated with this direct cost.

F.1.2 Indirect Capital Costs

Indirect capital costs are those costs associated with engineering design, contingency, construction oversight, administration, and community relations. These costs were estimated based on previous experience during interim source removal and the remedial investigation of the Site. Tables F-3 presents a breakdown of the estimated indirect costs by alternative.

The following assumptions were incorporated into the estimates for indirect cost for each alternative:

- Implementation will be directly related to the amount of soils handling;

- Engineering design costs are estimated at 5 percent of the direct costs;

- Construction oversight costs are estimated at 10 percent of the direct costs;

- Administrative and reporting costs are estimated at 3 percent of the direct costs;

- Contingency allowances are estimated at 25 percent of the direct costs; and

- Four public meetings may be held during the design, construction, operation, and closure of the selected cleanup action. The costs of this effort are estimated at 1 percent of the direct costs.

The following assumptions for developing indirect costs were also developed and are applicable to each remediation unit and remedial alternative:

- Construction oversight is provided by a third party contractor;

- Community relations will be provided by company representatives and a third party contractor; and

- Ecology oversight, administration, and public meeting costs are not included in the estimated costs.

EPA guidance also recommends that the license and permitting costs be included. These costs were not included in the estimated indirect capital cost since obtaining permits for remediation activities under a state cleanup action is not required. The cleanup must otherwise conform to the substantive requirements of the regulation.

F.2 Total Estimated Cost

The preceding cost estimates are the basis for the estimated total cost for all remediation units of the Site. The sum of the direct costs and indirect costs are presented for each remediation alternative in Table F-4. The range of low and high total costs represent the range of direct costs and the corresponding contingency and engineering design ranges which are based on a percentage of the direct costs. Costs for the remediation of Miscellaneous Small RUs are listed on Table F-5.

Based on the preferred alternatives presented in Chapter 8 for remediation of in-place and stockpiled Site soils, and the completed interim source removal described in Chapter 1, the best estimate of total cost for Site remediation was prepared and is presented in Table F-6. Including accrued costs for studies,

sampling, legal fees, and communications etc., the total cost of Site remediation is approximately $64,000,000.

APPENDIX G – *ESTIMATION OF MINIMUM SOIL VOLUME REQUIRED FOR COST-EFFECTIVE ON-SITE TREATMENT*

To estimate the minimum soil volume required for treatment on Site, the remediation cost per unit volume (CY) was plotted as a function of soil volume for high, low, and average cleanup action cost options as presented on Figure G-1.

G.1 Assumptions

- The high cost option is based on a high treatment cost of $200/CY and disposal as hazardous waste at $180/ton. The low cost option is based on a low treatment cost $90/CY and disposal as problem waste at $61.50/ton.

- Mobilization and demobilization costs were assumed to be $50,000 for the low cost option and $100,000 for the high cost option. These costs are based on ranges provided by vendors for stabilization and soil washing.

- All options include engineering design (12%) and contingency (25%) (10% engineering design and contingency are included in the off-Site disposal costs to account for costs of stockpile management and uncertainty in volume of impacted soil to be disposed of). Long-term maintenance and monitoring cost are not included.

- The average cost treatment is simply the arithmetic average of the high and low cost treatments.

G.2 Conclusion

- If a soil can be characterized as problem waste, direct disposal at an industrial landfill is the best option.

- If the soil is hazardous, it becomes cost-effective to treat the soil with an average cost treatment when the volume is greater than approximately 5,000 CY.

- If the equipment has already been mobilized on Site for other impacted soils, and the mobilization cost does not need to be included in the cost per CY, then average cost treatment is always more cost-effective than disposal as hazardous waste.

APPENDIX H – *Development of Soil Remediation Levels for the Golf Course Groundskeeper*

H.1 Introduction

This appendix presents a summary of the approach used to calculate soil remediation levels for areas included in the golf course land use areas, assuming that an engineered cap is placed over the contaminated soil. The approach used to calculate these levels is the same as that used to calculate Site-specific cleanup standards presented in Chapter 3 of the Human Health and Ecological Risk Assessment for the Former DuPont Works Site (PIONEER, 2002).

The equations used to calculate soil remediation levels for the golf course evaluation units were obtained from the Model Toxics Control Act (MTCA) – Washington Administrative Code (WAC) 173-340-745. Soil remediation levels were calculated using these equations considering the potential reasonable maximum exposure for golf course groundskeepers who may occasionally contact contaminated soil beneath the cap during intrusive maintenance activities, such as repairing sprinkler lines.

The Environmental Protection Agency (EPA) has chosen to evaluate the potential health effects of lead using a physiologically based model. Therefore, lead has not been assigned the toxicity values required to calculate Site-specific remediation levels using the equations presented in WAC 173-340-745. The model developed by EPA for establishing lead remediation levels in non-residential areas is the Adult Lead Model (EPA, 1996).

H.2 Development of Soil Remediation Levels for Golf Course Groundskeepers

The equations and input values used to develop soil remediation levels for golf course groundskeepers potentially exposed to constituents of concern (COCs) identified in the RA (other than lead) based on incidental soil ingestion are presented below.

Equation for Noncarcinogens:

WAC 173-340-745-1 – Soil Remediation Level (mg/kg) = $$\frac{RfD \; x \; ABW \; x UCF \; x HQG \; x AT_n}{SIR \; x AB1 \; x EF \; x ED}$$

Equation for Carcinogens:

WAC 173-340-745-2 – Soil Remediation Level (mg/kg) = $$\frac{CRG \; x ABW \; x AT_c \; x UCF}{CPF \; x SIR \; x AB1 \; x EF \; x ED}$$

Where;

Parameter	Description
EF	= Exposure Frequency (days/year)
ED	= Exposure Duration (years)
SIR	= Soil Ingestion Rate (mg/day)
AB1	= Gastrointestinal Absorption Fraction (AB1) (unitless)
ABW	= Body Weight (kg)
ATn & ATc	= Averaging Time (days)
RfD	= Noncarcinogenic reference dose (mg/kg-day).

CPF = Cancer potency factor $(mg/kg\text{-}day)^{-1}$.

UCF = Unit conversion factor (mg/kg).

HQG = Hazard quotient goal (i.e., 1)

CRG = Cancer risk goal (i.e., 1E-05).

H.2.1 Equation Input Values

The input values for these equations consist of exposure factors, which describe the exposure patterns of the receptors (i.e., exposure frequency, exposure duration, ingestion rate, gastrointestinal absorption fraction, body weight, and averaging time); toxicity values (i.e., reference doses and carcinogenic potency factors), and benchmark values (i.e., target hazard quotients and target cancer risks). These input values are discussed below.

H.2.2 Exposure Factors

Exposure factors are used to estimate the likely intake level of a constituent. The exposure factors used to calculate remediation levels were approved by Ecology (Ecology, 1998) and are described below:

- *Exposure Frequency (EF)* – The number of days per year that a person is exposed. For the golf course groundskeeper exposure is assumed to occur 12 days/year (i.e., once per month).

- *Exposure Duration (ED)* – The number of years over which exposure is assumed to occur. For the golf course groundskeeper the exposure duration was assumed to be 20 years, which is the MTCA default value for worker exposure duration.

- *Soil Ingestion Rate (SIR)* – The amount of soil ingested per day of exposure. For the golf course groundskeeper the soil ingestion rate was assumed to be 100 mg/day.

- *Gastrointestinal Absorption Fraction (AB1)* – This is the percentage of a constituent that is available for absorption by the gastrointestinal tract once ingested. This is typically a constituent-specific value, but based on direction given by Ecology this value was conservatively chosen to be 100% for all constituents.

- *Body Weight (ABW)* – The average body weight, in kilograms, of the receptor being evaluated. For the golf course groundskeeper this value was assumed to be the MTCA default of 70 kg, the average weight of an adult (average of both females and males).

- *Averaging Time (Atn and Atc)* – The number of days over which exposure is averaged. Exposure levels for carcinogens are averaged over the lifetime of the exposed individual (i.e., 75 years) while exposure levels for noncarcinogens are averaged over the duration of exposure. Therefore, for carcinogens, the averaging time is calculated as the exposure frequency (days/year) X 75 year life expectancy. The averaging time for noncarcinogens is calculated as the exposure frequency (days/year) X exposure duration (years).

The exposure factors used to calculate soil remediation levels are presented in Table H-1.

H.2.3 Toxicity Values

The toxicity values used to develop soil remediation levels include noncarcinogenic reference doses (RfDs) and carcinogenic potency factors (CPFs) are presented in Table H-1. The following sources of toxicity information were consulted to identify the toxicity values used to develop the soil remediation levels:

- The Integrated Risk Information System (IRIS) (EPA, 2001).

- The Health Effects Assessment Summary Tables–Annual Update (HEAST) (EPA, 1997).

- Ecology's Cleanup Levels and Risk Calculation (CLARC) Table Updates (Ecology, 2001a).
- EPA Region IX Preliminary Remediation Goal (PRG) Tables (EPA, 2000).

Since multiple toxicity values were available for some chemicals, the sources of toxicity information were prioritized as follows to select the toxicity values used in the development of soil remediation levels:

1. IRIS values.
2. HEAST values.
3. CLARC table values.
4. PRG table values.

H.2.4 Benchmark Values

The last category of equation input values are the risk benchmark values, used to define the "acceptable" risk level for a person exposed to Site contamination. The benchmark values used are the hazard quotient goal (HQG), which is the benchmark for noncarcinogenic effects, and the cancer risk goal (CRG), which is the benchmark for carcinogenic risk. A description of these values is presented in Chapter 3 of the RA. In calculating soil remediation levels for the golf course groundskeeper, the benchmark values used were a HQG of 1.0 and a CRG of 1 in 100,000 (i.e., 1E-05) for individual constituents. These are the benchmark values for industrial exposures stipulated in MTCA (WAC 173-340-745).

H.3 Development of Soil Remediation Levels for Lead

EPA's Adult Lead Model used to calculate soil remediation levels for lead is described in Chapter 3 of the RA (PIONEER, 2002) and (EPA, 1996). The model input values used for the golf course groundskeeper are presented in Table H-2; the lead remediation level obtained from this calculation is presented in Table H-3 along with the other Site-specific remediation levels calculated for golf course development.

Results		
RBRG[3]	ug/g	4,134[2]

Notes:
[1]These Site-specific values were specified for use by Ecology (Ecology, 1997).
[2]This value was rounded down to 4,100 ug/g (note: 4,100 ug/g = 4,100 mg/kg).
[3]Risk-based remediation goal.

Table H-3 – Golf Course Groundskeeper Soil Remediation Levels[1]

Constituent	Golf Course Groundskeeper Soil Remediation Level (mg/kg)
Explosives	
2,4,6-Trinitrotoluene[2]	10,600
Inorganics	
Arsenic	530
Lead[3]	4,100
Mercury[4]	6,390
PAHs	
Benzo(a)Pyrene	109
Pesticides	
Aldrin	47

Notes:
[1]Where remediation levels were calculated for both carcinogenic and noncarcinogenic effects, the value presented in the table is the lower of the two values. The soil remediation levels presented in Table 3 have been rounded down from the values shown in Table 1.
[2]Based on agreement with Ecology, the Site-specific cleanup level for 2,4,6-Trinitrotoluene is 1.75 mg/kg (Ecology, 2001b)
[3]Value was derived using EPA's Adult Lead Model (EPA, 1996).
[4]Based on agreement with Ecology, the Site-specific cleanup level for mercury is 24 mg/kg (Ecology, 1993).

APPENDIX I – *Impractability of Groundwater Remediation at the Former DuPont Works Site, DuPont, WA*

I.1 Introduction

The cost for pumping and treating groundwater at the Former DuPont Works Site (Site) to meet the DNT drinking water screening level would be substantial and disproportionate to the degree of risk reduction which could be achieved. Therefore, in accordance with MTCA (WAC 173-340-360, it is impractical to consider active groundwater remediation at the Site for an end use (drinking water) that is not planned. This conclusion is based on the following:

- Site groundwater poses no risk to human health or the environment.
- Because off-Site drinking water supplies will supply more than double the full projected population of DuPont through the year 2020, Site groundwater is not currently and will not in the future be used as a drinking water source (due to a deed restriction).
- Future Site development plans will include deed restrictions as necessary to prevent drilling of drinking water supply wells;
- Even assuming a hypothetical drinking water exposure that does not and will not exist at the Site, the highest DNT concentrations currently in Site aquifers (less than 0.5 µg/L) represent a worst-case risk of less than 4×10^{-6}, which meets a risk threshold of $1 \times l0^{-5}$;
- Current DNT concentrations pose no risk to golfers, other visitors, or golf course maintenance workers who would be most likely to encounter Site groundwater on a regular basis when it is used for golf course irrigation; and
- Site groundwater poses no risk to any Site ecological environment (including Sequalitchew Creek and Old Fort Lake) or off-Site ecological environment (e.g. Puget Sound).
- Natural groundwater recovery will occur following the completed interim DNT source removal. Removal of more than 40,000 cubic yards of DNT-impacted Site soils has been completed, thus the source of DNT to Site groundwater has been removed;
- Already low DNT concentrations in Site groundwater will decline further because Site aquifers are highly permeable and DNT is mobile. This allows for natural flushing of DNT from the groundwater system and further reductions over time in the already low risk under a hypothetical drinking water scenario; and
- The current Site groundwater monitoring program will continue to document the DNT concentrations over time.

Acknowledging groundwater pump and treat systems poor historical performance in achieving drinking water standards, the existing DNT concentrations in Site groundwater would represent a reasonable remediation endpoint at sites where active remediation is under consideration or underway.

The cost to implement active groundwater remediation would be excessive, with preliminary estimates ranging between 33 and 58 million dollars. Consistent with the intent of MTCA and CERCLA, resources should be directed toward making substantive reductions in overall Site risk, which will be best accomplished at this Site by addressing other contaminants remaining in soils.

I.2 Site Groundwater Poses No Risk to Human Health or the Environment

DNT is the only constituent present in Site groundwater at concentrations above drinking water screening levels. The concentrations of DNT in Site aquifers are very low (maximum 95% UCL is less than 0.5 µg/L) and do not represent a risk as explained below.

I.2.1 Site Groundwater Poses No Risk to Human Health

Based on data collected, the highest average DNT concentration in an aquifer beneath the Site is 0.47 µg/L (95% UCL for MW-22). The MTCA drinking water screening level of 0.13 µg/L is based on a 1×10^{-6} risk level. The worst-case risk based on a hypothetical Site drinking water exposure scenario (drinking current DNT concentration in MW-22 for 30 years) is less than 4×10^{-6} which is below the MTCA risk threshold of 1×10^{-5}.

Site groundwater is not being used for drinking water under current Site conditions, and it will not be used in the foreseeable future because adequate off-Site drinking water supply exists to meet future demand. For a projected full build-out population of 10,000 people at the year 2020 (McCamett, June 1995) and an average water consumption of 150 gallons per capita day (Clark et a1, 1977; Metcalf and Eddy, 1979; Linsley and Franzini, 1979), the City of DuPont will have an estimated maximum water demand of approximately 1.5 million gallons per day (MGD). The City of DuPont's existing water system will supply this demand while maintaining excess reserve capacity. The two existing Bell Hill wells have permitted water rights of 2.0 MGD; additions to the system may include an additional well(s) at Hoffman Hill which could potentially double the supply capacity. The Bell Hill wells are located hydraulically up-gradient of the Site and are incapable of drawing water from beneath the Site. As part of the Bell Hill water rights permitting process Ecology reviewed and concurred with technical evaluations (Hart Crowser, 1991) supporting the long-term safety of the Bell Hill water supply even under continuous maximum production. Similarly, Hoffman Hill is located cross-gradient of the Site and wells drilled there would be developed to prevent drawing any groundwater from beneath the Site. Off-Site water supply from the Bell Hill and Hoffman Hill well alone will support more than double the projected population of the City of DuPont, without additional water supply development.

There is no need for drinking water wells to be drilled within the Site under any foreseeable development scenario. As a final measure of protection, Site development plans will include institutional controls, as necessary, in the form of deed restrictions to prevent drilling of wells within the Site for the purpose of water supply.

In addition, Site groundwater poses little to no risk to golfers, visitors, or golf course maintenance workers from dermal contact with irrigation water or from drinking of irrigation water. Attachment A provides a screening evaluation of potential risk to a golf course worker, the person most likely to come in contact with irrigation water.

I.2.2 Site Groundwater Poses No Risk to the Environment

DNT concentrations discharging in seeps to Puget Sound are an order of magnitude below the surface water screening level (an ARAR) of 9.1 µg/L, which is protective of marine aquatic life. DNT was not detected in Sequalitchew Creek or springs discharging to it, or in Old Fort Lake, indicating no potential risk to freshwater aquatic life.

DNT was not detected in samples of marine sediments collected at locations where Site groundwater discharges to Puget Sound or in samples of freshwater sediments from Sequalitchew Creek or Old Fort Lake.

DNT is not detectable in surface water or sediments within or adjacent to the Site, and concentrations in Site groundwater discharging to Puget Sound are below the surface water quality standards.

I.3 Groundwater Recovery Will Occur Naturally

The extensive interim DNT source removal has been successful in removing the vast majority of DNT-impacted soils from the Site. Groundwater flow rates at the Site are very high leading to rapid flushing of the aquifers. As a result, natural recovery of Site groundwater should occur relatively rapidly.

I.4 The DNT Source Has Been Removed

Been 1992 and 1995, more than 40,000 cubic yards of Site soils with DNT concentrations above 3 mg/kg were removed in the five areas where DNT was detected above 1 mg/kg (RI Areas 5, 10, 18, 25, and 31). Data from hundreds of designation samples collected from excavated soils and hundreds of verification samples collected from the excavations suggest that the vast majority of DNT mass (nearly 5,300 kg. or more than 5 tons) has been removed from these two areas. These data, and verification data from the other smaller areas, indicate that the DNT source has been effectively removed from the Site. The most important step in facilitating natural groundwater restoration is removal of the source to prevent further DNT leaching to groundwater. This has been accomplished at the Site.

I.5 Rapid Natural Groundwater Flushing in Site Aquifers

Aquifers beneath the Site are highly permeable (including the exceptionally permeable Steilacoom Gravels), resulting in estimated groundwater flow rates likely on the order of 5,000 to 8,000 feet per year (median values for the Water Table and Unconfined Sea Level Aquifers from ranges presented in Hart Crowser, 1994). The large quantities of groundwater flushing naturally through the aquifers each year will be effective in further reducing the already low residual DNT concentrations in Site aquifers. There is sufficient water moving through the groundwater system under ambient conditions to achieve natural recovery (reducing DNT to below the drinking water screening level) without attempting to supplement the process with active groundwater treatment.

A pump and treat system would involve the same mechanism for aquifer restoration as is occurring naturally via groundwater discharge from the Site (that is removal of water containing DNT from the aquifer system). In a hypothetical pump and treat system, pumpage from the Sea Level Aquifer (SLA) would be approximately equal to the quantity of water discharging naturally from the Site via the SLA. A Site pump and treat system would also include pumping from a portion of the Water Table Aquifer (WTA). Preliminary pumping rate estimates indicate that pumpage from the WTA would comprise about 20 percent and pumpage from the SLA about 80 percent, of the total water pumped in a hypothetical Site pump and treat system (pumping rate estimates discussed below). Aggressive pump and treat of both Site aquifers would provide a 25 percent increase in water removed from the aquifer system relative to natural discharge, which, in time, could decrease the aquifer restoration time by only 20 percent relative to natural flushing. [A 20 percent decrease in time is based on a simple “batch flush” model ($t = \ln[Ct/Co] * PV * R / Q$; EPA, 1988). Increasing flow rare, Q, by 0.25 decreases restoration time, t, by 0.20 in this model. Other values in the equation would be constants for this demonstration.]

I.6 Technical Infeasibility Considerations

Groundwater pump and treat is the only groundwater remediation technology which could be applied at the Site for the following reasons:

- Groundwater which would be targeted for remediation is deep (100 to 200 feet below surface) and laterally extensive, preventing use of impermeable barriers, gates, or other groundwater isolation techniques;

- DNT has low volatility, preventing use of sparging or other venting technologies;

- Although DNT can be degraded through natural in situ processes, only biological degradation could potentially occur in Site aquifers and attempting to enhance this process as part of a remediation program would likely be infeasible;

- DNT readily degrades by photolysis (half-life on the order of days; Etnier, 1987), but this process will not occur in aquifers;

- DNT can be transformed to formic and acetic acids, but only at temperatures at which water would not persist (520°F; Etnier, 1987); and

- DNT in water degrades through biological processes under some aerobic and anaerobic conditions (Spanggord. 1980; Etniert 1987), but the metabolism of DNT is strongly dependent on environmental conditions and the presence of viable microorganisms (ATSDR, 1989). Biodegradation of DNT may be occurring naturally in Site aquifers, yet attempting to establish or enhance appropriate natural microorganism populations (e.g., by introducing nutrients) in Site aquifers would likely be infeasible because of the size of the Site and the substantial depth of the aquifers.

The National Research Council (NRC) Committee on Ground Water Cleanup Alternatives' published report lists "conventional pump and treat" as the only effective technology (out of 12 technology categories) for dissolved constituents, which are non-reactive or non-volatile (NRC, 1994). DNT in Site groundwater falls into this category.

In a pump and treat scenario, groundwater extracted from Site aquifers would be treated most cost-effectively using granular activated carbon (GAC). Recent studies at another site have demonstrated that GAC is considerably more cost-effective to use than advanced oxidation technologies (e.g. UV/Ozone) at low influent concentrations (Hart Crowser, 1993).

The historical performance of groundwater pump and treat systems in restoring aquifers to drinking water standards has been poor suggesting that groundwater pump and treat to achieve drinking water standards everywhere in an aquifer may be technically infeasible. This fact is widely acknowledged within the environmental industry, including the EPA (Travis and Doty, 1990; Doty and Travis, 1991; EPA, 1992; Makdisi, 1994). Of 77 pump and treat sites evaluated in the NRC (1994) report, eight small sites (pumping rates between 1 and 37 gpm; 5 were service stations) with volatile organic compounds (VOCs) had apparently achieved cleanup goals, some of which had the benefit of using venting/sparging to enhance VOC removal. In contrast, the Former DuPont Works Site is very large and hydro-geologically complex and DNT would need to be extracted solely through conventional groundwater pumping. Therefore, the time required for pump and treat to achieve the DNT drinking water standard throughout the Site could be approximately 10 to 20 years or longer, if it were to be implemented. One-half of the sites evaluated by the NRC have already been pumping and treating for at least 10 years without achievement of drinking water standards (NRC, 1994).

At other sites where groundwater concentrations are orders of magnitude higher than at this Site, pump and treat may make sense for reducing concentrations (thus reducing risk) to the extent practical. General evaluations of pump and treat performance suggest it would not be unreasonable to expend 50 percent of available resources (time and money) initially reducing groundwater concentrations by 90 percent, and then expend the remaining 50 percent attempting to remove the residual 10 percent (i.e., below some low asymptotic level). Maximum DNT concentrations at the Site would likely fall within the final one percent at sites where active groundwater remediation is undertaken.

I.7 Cost of Active Groundwater Remediation

The cost to implement active groundwater remediation (pump and treat) at the Site would be excessive, primarily because of the high groundwater flow rates and resulting large volume of water which would need to be extracted, treated, and reintroduced to Site aquifers.

I.7.1 Groundwater Pumping Rate Estimates.

The following analytical equation presented in Keely (1984) was used to estimate the pumping rate needed to capture all Site groundwater with DNT concentrations above 0.13 μg/L in the Water Table Aquifer and in the Sea Level Aquifer:

(1) Max width of capture zone (w) = Q / H v n (I)

where:

Q = pumping rate in ft^3/day;
H = initial saturated thickness in feet;
v = average linear groundwater velocity in ft/day; and n = effective porosity (dimensionless).

Because average linear velocity (v) is equal to Ki/n, effective porosity drops out of the equation. Rearranging the equation to solve for pumping rate (Q) then gives:

(2) Q = w H K i (2)

where:

Q, w, and H are defined above;
K = hydraulic conductivity in ft/day; and
i = hydraulic gradient in ft/foot.

Equation (2) was solved using Monte Carlo simulation to develop a probabilistic range of pumping rates which encompasses reasonable ranges of uncertainties in hydraulic parameters. The equation was solved independently for the Water Table Aquifer (assuming capture of groundwater in Area 18 with DNT above 0.13 μg/L) and the" Sea Level Aquifer (assuming capture of all groundwater in the Sea Level Aquifer with DNT above 0.13 μg/L) .The flow rates from the two aquifers were added to provide an estimated total system now rate for a hypothetical Site pump and treat system.

Hydraulic parameters were assigned assumed probability distributions based on information presented in the initial Draft RI (Hart Crowser, 1994). The assumptions follow, and are provided in Attachment B.
Water Table Aquifer (WTA) Assumptions:

- Hydraulic conductivity (K) was assigned a lognormal distribution with geometric mean of 5×10^{-2} cm/sec and a standard deviation of 10 percent of the mean. [This compares favorably with reliable pumping test results from Fort Lewis which provide a K estimate for the Water Table Aquifer (WTA) of 2×10^{-1} cm/sec, which is higher than the range presented in the initial RI. This value is consistent with the coarse-grained nature of the WTA. Based on this value and other WTA pumping test results presented in the initial Draft RI, we assumed 5×10^{-2} cm/sec as our best judgment estimate of an average K value. Because these flow rate estimates are most sensitive to uncertainty in K (which can vary by orders of magnitude) relatively small standard deviations (for both aquifers) were assumed about the mean values in an effort to provide a more tightly constrained, thus useful, range of resultant flow rates.]

- Horizontal hydraulic gradient (i) estimates for the WTA, ranging from 0.02 to 0.05 ft/ft are based on water table elevation contour maps. Hydraulic gradient for the WTA was assigned a triangular distribution with minimum, most likely, and maximum values of 0,02, 0.035 (midpoint of range), and 0.05 ft/ft, respectively,

- The thickness of the WTA was assigned a triangular distribution with minimum, most likely, and maximum values of 10, 30, and 50 feet, respectively, based on geologic information from drilling Site monitoring wells.

The width of the WTA to be captured was assigned a triangular distribution with minimum, most likely, and maximum values of 1,200, 1.600, and 2,000 feet, respectively, based on the locations of interim DNT

source removal excavations and groundwater flow directions presented in the Draft RI.

I.7.2 Sea Level Aquifer (SLA) Assumptions

- Hydraulic conductivity was assigned a lognormal distribution with geometric mean of 1 x 10^{-1} cm/sec (midpoint of the range presented in the Draft RI) and a standard deviation of 10 percent of the mean (as discussed above).

- Horizontal hydraulic gradient (i) estimates for the Unconfined SLA ranging from 0.005 to 0.02 ft/ft were based on water table elevation contour maps. Hydraulic gradient for the SLA was assigned a triangular distribution with minimum, most likely, and maximum values of 0.005, 0.013 (midpoint of range), and 0.02 ft/ft, respectively.

- The thickness of the SLA was assigned a triangular distribution with minimum, most likely, and maximum values of 80, 100, and 120 feet, respectively based on geologic information from drilling of a deep test well north of the Site which penetrated approximately 120 feet of saturated Steilacoom Gravels (Unconfined Sea Level Aquifer).

- The width of the SLA to be captured was assigned a triangular distribution with minimum, most likely, and maximum values of 2,000, 2,500, and 3.000 feet, respectively, based on the distribution of DNT within the Unconfined Sea Level Aquifer.

Using these parameter distributions as input, equation (2) was run as a Monte Carlo simulation using Crystal Ball software, a forecasting and risk analysis add-on to the Excel spreadsheet. The equation was solved for each aquifer 5,000 times by randomly selecting parameter values from the aquifer-specific probability distributions outlined above, and summing the flow rates from both aquifers into an estimated total system flow rate. The 5,000 estimates of the total system flow rate were automatically compiled into a probability distribution for which percentiles are provided. Attachment B provides the supporting information for the now rate estimates (including assumptions, forecasts, and statistical output).

Using the probability distribution for total system flow rate, we selected a range of system flow rates corresponding to 95 percent and 25 percent probabilities (i.e., a reasonable range of likely outcomes) for the purposes of developing a range of cost estimates. Based on the Monte Carlo simulation, the 5^{th} percentile value was approximately 3,500 gpm (95 percent probability that the flow rate would be at least that high; refer to page B-2 in Attachment B) and the 75^{th} percentile value was approximately 7,000 gpm (25 percent probability that it would be that high). This range of flow rates appears reasonable when compared with a relatively large-scale pump and treat system operating at Ponders Corner, approximately 5 miles from the Site, which had pumped 2,000 gpm from only the lower permeability portion (Advance Outwash) of the Water Table Aquifer (EPA, 1992).

I.7.3 Preliminary Cost Estimate for Groundwater Remediation

Using the estimates for pumping rates presented above, preliminary estimates of cost range from approximately $33 million (assuming pumping, treatment by granular activated carbon (GAC), and reintroduction to the aquifer of 3,500 gpm [5 MGD] for a 10-year duration) to approximately $58 million (assuming pumping, treatment, and reintroduction to the aquifer of 7,000 gpm [10 MGD] for a 20-year duration). A ten (10) year duration of operation was based on the findings of the NRC (1994) report, where one-half of all systems studied have already been operating 10 years or more (with a maximum of 21 years). As such, the twenty (20) year duration was used as the high-end estimate for the purposes of developing cost estimates.

The cost estimates were developed using EPA's Cost of Remedial Action (CORA) Model (CH2M Hill, 1990). The preliminary cost estimate included the following components;

- Installation of extraction wells;

- Installation of conveyance (piping) systems;
- Purchase and operation of granular activated carbon (GAC) treatment system (including carbon change out and off-Site thermal regeneration);
- Installation of re-introduction wells to return treated groundwater back to the aquifers (also used to help control saltwater intrusion in the Sea Level Aquifer);
- Performance monitoring for full period of operation; and
- Operation and maintenance of all systems for period of operation.

Table 1 provides a summary of CORA's estimated costs for constructing (capital costs) and operating and maintaining (O&M costs) a groundwater pump and treat system at the Site under four assumed scenarios (5 MGD for 10 or 20 years, and 10 MGD for 10 or 20 years). These cost estimates do not include pilot testing or engineering design.

I.8 Conclusions

For the Former DuPont Works Site, there is a clear case that the cost to implement active groundwater remediation would be substantial and disproportionate to any risk reduction it could achieve, as specified in MTCA.

- First, there is no risk to human health or the ecological environment posed by DNT in groundwater under any current or foreseeable future land use of the Sire; ample off-Site water supply exists to meet all future drinking water demand, and intuitional controls will be implemented, as necessary, during future Site development to prevent withdrawal of Site groundwater for drinking water use;
- Second, the DNT source at the Site has been removed so that natural recovery will be effective in further reducing the extremely low DNT concentrations currently detected in Site groundwater;
- Third, concentrations in Site groundwater are already low enough that active groundwater pump and treat would likely be little or no more effective than natural flushing in removing the last residual DNT from Site aquifers; and
- Finally, the cost to undertake groundwater pump and treat would be excessive, particularly since it would not provide a substantive reduction in Site risk.

The intent of MTCA and CERCLA is to focus cleanup resources to reduce overall Site risk under current and future land use. This will be accomplished at the Former DuPont Works Site by addressing Site soils, not Site groundwater.

Table I-1 – Summary of Cost[(1)] Estimates for Implementing Groundwater Pump and Treat for the Former DuPont Works Site

Scenario	Capital Cost	O & M Costs[(2)]	Total Cost
5 MGD for l0 years	$16.5	$16.7	$33
5 MGD for 20 years	$16.5	$23.0	$40
10 MGD for 10 years	$20.0	$27.0	$47
10 MGD for 20 years	$20.0	$38.0	$58

Notes:
[(1)]Cost estimates developed using CORA -EPA's Cost of Remedial Action Model (CH2M Hill, 1990). All costs in millions.
[(2)]Present worth based on 10% annual interest rate.

ATTACHMENT A
GROUNDWATER RISK SCREENING EVALUATION

ATTACHMENT A
GROUNDWATER RISK SCREENING EVALUATION

The potential risks associated with groundwater at the Site are expected to be minimal because the future uses are limited and because the RI results indicate that low concentrations of DNT represent the only Site-related constituents present in the groundwater.

Irrigation of the golf course after the Site is developed represents the only potential future use of groundwater at the Site. No other future uses are planned because the City of Dupont will provide water for all residential and industrial uses. Golfers or occasional visitors are not expected to come in contact with the irrigation water on any significant basis. Thus, risks were quantified for exposure by a golf course worker responsible for operating the irrigation system. Risks were evaluated assuming dermal contact with irrigation water as well as drinking of the irrigation water. Because of the greater potential frequency and duration of contact with irrigation water, a golf course worker represents the most conservative exposure scenario. Highly conservative assumptions were used throughout this screening evaluation to provide a high level of confidence that use of Site groundwater for golf course irrigation will be protective of human health.

The potential cancer risks associated with exposure to groundwater are below 1×10^{-6}, even with the highly conservative assumptions used in this screening evaluation. Therefore, groundwater does not represent a media of concern for impact to human health. The potential risks were quantified as presented below:

Dermal Contact with Groundwater

The dermally absorbed dose is calculated with the following equation:

$$DAD = \left(\frac{DA_{event} \times EV \times ED \times EF \times A}{BW \times AT} \right)$$

Where:

DAD =	dermally absorbed dose in mg/kg-day
DA_{event} =	absorbed dose per event in mg/cm^2-event
EV =	event frequency in events/day
ED =	exposure duration in years
EF =	exposure frequency in days/year
A =	skin surface area available for contact in cm^2

BW = body weight in kg
AT = averaging time in days

The following values were substituted into the above equation:

DA_{event} = 5.9×10^{-9} mg/cm^2-event; as calculated separately below
EV = 1 event/day; which assumes that a groundskeeper sets up and attends to watering systems once per day
ED = 9 years
EF = 180 days/year; a Site-specific value suitable for the Pacific Northwest climate
A = 2,000 cm^2; equal to the average surface area of an adult's hands and forearms
BW = 70 kg; MTCA and EPA default value
AT= 25,550 days; the averaging time for carcinogens (70 years) times 365 days/year

DA_{event} is calculated with the following equation:

$$DA_{event} = 2K_p C_v \sqrt{\frac{6\,\tau\, t_{event}}{\pi}}$$

Where:
K_p= chemical-specific permeability constant in cm/hour
C_v= chemical concentration in water in mg/cm^3
τ = lag time in hours; this term is used to account for chemicals entering the skin at a rapid rate during initial contact (a non-steady state phenomenon)
t_{event}= the duration of the exposure event in hours
π = pi; a constant equal to 3.14

Values of 3.8×10^{-3} cm/hour and 1.1 hour for K_p and τ, respectively, were taken from EPA (1992). The value of K_p for 2,4-DNT was used as the higher value for the two given DNT isomers. t_{event} was assumed to be equal to 0.5 hour, which is a conservative approximation of the amount of time a golf course worker might be in contact with irrigation water per exposure event. C_v was assumed to be 0.76 μg/L, the highest DNT concentration ever detected in Site aquifers (converted to 7.6×10^{-7} mg/cm^3) as an additional measure of conservatism.

Calculating DA_{event} with the above values results in $DA_{event} = 5.9 \times 10^{-9}$. Substituting this into the equation used to calculate DAD results in DAD = 1×10^{-8}. Multiplying DAD by the oral CSF of 0.68 gives an estimated

risk by this pathway of 7×10^{-9}, or 7 in 1 billion. Therefore, potential incremental risks associated with this pathway are well below thresholds of risk management consideration, even with the highly conservative assumptions that a worker would have their arms immersed in water containing maximum Site DNT concentrations for a period of one-half hour every day for 180 days per year.

For EF, the upper-bound default for worker exposure is normally 250 days/year. However, the climate in the Pacific Northwest is such that golf course irrigation is not expected to exceed 6 months per year. Assuming the golf course is operating 7 days per week for 6 months, an EF of 180 days/year was assumed. This further assumes that the golf course will be watered on every one of those 180 days, which is a conservative assumption.

The event time and frequency of 0.5 hour/event, 1.0 event/day, respectively, may not capture the actual conditions by which a worker is exposed. Assuming that a worker makes contact with the irrigation equipment or with materials that have come into contact with the irrigated sections of the golf course, exposure may, in fact, occur with greater frequency for much shorter periods of time. To examine this, the above calculations were repeated with $\tau_{event} = 0.1$ hour (six minutes), and EV = 16 events/day. That is, an individual makes contact with irrigation water for 6 minutes out of every 15 minutes for four hours each working day, which are highly conservative assumptions. With these values substituted in the above equations, $DA_{event} = 2.6 \times 10^{-9}$, DAD = 7.7×10^{-8}, and the risk is determined to be 5×10^{-8}, or 5 in 100 million. Therefore, exposures of greater frequency and shorter time still results in estimated potential incremental risks well below risk management thresholds.

Ingestion of Groundwater

The orally absorbed dose is calculated with the following equation:

$$Intake = (mg/kg\text{-}day) = \left(\frac{CW \times IR \times EF \times ED}{BW \times AT}\right)$$

Where:

CW =	chemical concentration in water in mg/L
IR =	ingestion rate in liters/day
EF =	exposure frequency in days/year
ED =	exposure duration in years
BW =	body weight in kg

AT = averaging time (period over which exposure is averaged - days)

The following values were substituted into the above equation:

CW = 0.76 μg/L, the highest detected DNT concentration in groundwater at the Site
IR = 1 liter/day. This equals half of the EPA default IR of 2 liters/day
EF = 180 days/year; a site-specific value suitable for the Pacific Northwest climate
ED = 9 years
BW = 70 Kg; MTCA and EPA default value
AT = 25,550 days; the averaging time for carcinogens (70 years) times 365 days/year

The value of 1 liter per day for the IR is based on the assumption that a golf course worker consumes half their daily intake of 2 liters/day from irrigation water while at work. This represents a highly conservative assumption since it assumes a worker would preferentially drink water from the golf course irrigation system rather than the water specifically provided for drinking water at the golf course (from the City of Dupont water supply). Because water used for irrigation may not be suited for drinking water purposes, the assumption of any drinking water exposure to irrigation water, much less half of their intake, is highly conservative. Values for CW, EF, ED, BW, and AT are the same as used above for dermal exposure.

Potential risk was calculated for both carcinogenic and non-carcinogenic end points for exposure to DNT in drinking water using EPA guidance (1989). A cancer slope factor of 0.68 and an oral reference dose of 0.001 mg/kg-day were used. The cancer risk was calculated as 5×10^{-7}, considerably below 1 in 1 million (10^{-6}). The non-cancer risk was calculated as 7×10^{-4}, much less than a hazard quotient of 1.0. These calculated risks are well below risk management thresholds.

July 2003

PREFACE

This volume, the Remedial Investigation for the Former DuPont Works Site (the Site), is the first of a series presenting information developed as part of the Final Remedial Investigation, Risk Assessment, and Feasibility Study (RI/RA/FS) for the Site, located in DuPont, Washington. Preparation of these reports was stipulated in the July 1991 Consent Decree, between the Washington State Department of Ecology (Ecology) and the potentially liable parties, (PLP) Weyerhaeuser Company (Weyerhaeuser) and E.I. DuPont de Nemours and Company (DuPont). Per the Consent Decree, the reports were developed in accordance with the Model Toxics Control Act (MTCA) cleanup regulations. Draft RI/RA/FS reports were completed in 1994 (Hart Crowser 1994d, 1994e, 1994f) and submitted to Ecology. The Final RI/RA/FS reports have been developed to satisfy comments on the draft reports and to accurately reflect existing conditions and planned future land use at the Site. These reports incorporate agreements reached with Ecology between 1991 and 2001.

A brief description of each report follows:

- **Remedial Investigation.** The purpose of this RI was to collect, develop, and evaluate sufficient information regarding the Site to enable the completion of the RA and FS. The RI characterizes the nature and extent of contamination in the context of past activities at the Site. The RI report presents the analytical data that have been collected at the Site. The data are presented for each RI area; these areas were defined on the basis of historical manufacturing and production operations at the Site.
- **Risk Assessment.** The RA evaluates Site conditions in relation to planned future land uses at the Site. The RA identifies soil cleanup concentrations and presents the methods used to derive Site-specific soil concentrations that are protective of human health and ecological receptors. These cleanup goals are compared to Site constituent concentrations in order to identify the areas that require additional evaluation in the FS.
- **Feasibility Study.** The FS evaluates alternative potential cleanup methods designed to meet the remedial action objectives. The FS report provides information for Weyerhaeuser and DuPont to recommend alternatives for remediation of selected areas, including both no action and action alternatives. Ecology will evaluate the FS and select the remedial measures it believes are appropriate in the Cleanup Action Plan. Weyerhaeuser and DuPont will complete the needed detailed design and implementation of the remedy selected by Ecology.

EXECUTIVE SUMMARY

The purpose of this Remedial Investigation (RI) is to collect, develop, and evaluate sufficient information regarding the Former DuPont Works Site (the Site) to characterize the nature and extent of contamination in the context of past activities at the Site (Figure 1-1). This RI report presents the analytical data that have been collected at the Site. The data are presented for each RI area (Figure 1-2 and Table 1-1), as defined on the basis of historical manufacturing and production operations at the Site.

PROPERTY HISTORY

The Site property was originally used by Native Americans. In the 1830s, Europeans settled in the area and built Fort Nisqually in the northern portion of the Site. Ten years later, the Fort was rebuilt at a location adjacent to but outside the eastern edge of the Site.

E.I. DuPont de Nemours and Company (DuPont) acquired the property in 1906 and constructed an explosives plant and the historical village of DuPont as a company town for plant workers. DuPont continued to manufacture explosives until the mid-1970s, when it closed the manufacturing operations and sold the property to the Weyerhaeuser Company (Weyerhaeuser). Weyerhaeuser and its subsidiary Weyerhaeuser Real Estate Company (WRECO) still own approximately 2,500 acres in the area that they named Northwest Landing. Northwest Landing is a planned community within the City of DuPont and it includes the Site. WRECO has begun to develop Northwest Landing on some of its lands within the City, but no development of the Site has occurred.

REGULATORY HISTORY

The Site was used for the manufacture of commercial explosives from 1909 to 1976. Production of explosive materials ceased and cleanup of the buildings began in 1976. As part of the cleanup process, asbestos was removed, salvageable materials were taken out, and structures were either burned or demolished. Actions taken at the Site subsequent to Weyerhaeuser's purchase include the following:

- In 1985, studies were conducted were concluded to determine whether hazardous substances were present.
- In 1986, a Phase I Site Survey and Review was performed was performed to identify areas of environmental concern on Site.
- In 1986, soil contamination was documented and reported to the Washington State Department of Ecology (Ecology).
- In 1987, a Phase II Site Characterization study was performed.
- In 1989, a Baseline Human Health RA was conducted.
- In 1991, Weyerhaeuser and DuPont signed a Consent Decree (No. 91 2 01703 1) with Ecology, in which they agreed to study the Site and complete an RI, RA, and FS.
- In 1994 and 1995, Draft RI, RA, and FS reports were submitted to Ecology (Hart Crowser 1994d, 1994e, 1994f).
- In 1996, Ecology approved a Cleanup Action Plan for a portion of the area (Parcel 2).

- In 1997, Parcel 2 was deleted from the Consent Decree, and a deed requiring institutional controls to maintain the industrial use of the parcel was recorded in the Pierce County Auditor's office.
- Between 1990 and 2001, Weyerhaeuser and DuPont undertook Interim Source Removal (ISR) actions to clean up soil and/or debris at the Site, in accordance with the Model Toxics Control Act (MTCA) and the Consent Decree.

SCOPE OF RI CHARACTERIZATION

The scope of the Site RI includes sample collection, laboratory analyses, data evaluation, and presentation of sampling results from four environmental media, as follows:

- 21,933 soil sample analyses (5,182 samples)
- 1,181 freshwater sediment sample analyses (20 samples)
- 12,038 groundwater sample analyses (283 samples)
- 1,528 surface water sample analyses (344 samples)

All RI data were collected in accordance with the Site Management Plan (Hart Crowser 1992a). Only those data representing current Site conditions within the Consent Decree Boundary (CDB) have been used in this RI. Data from sampling points that were removed during ISRs have been deleted from the RI database because they no longer represent current Site conditions.

SOIL QUALITY

Sampling Approach

Soil sampling locations were chosen on the basis of historical maps, former DuPont employee information, other Site information, statistical needs, and public comments. Additional samples were collected on the basis of an evaluation of initial sampling results, to evaluate whether the lateral and vertical extent of constituents of concern had been determined. Each RI sample was analyzed for one or more constituents.

Sampling Results

The RI areas from which soil samples were collected are shown in Figure 1-2. Data from the pre-RI and RI sampling and analysis indicate that the highest constituent concentrations occur in surface soil samples collected in the vicinity of production building foundations and waste disposal locations. Constituents of concern found in the production/disposal locations are associated with activities that occurred during facility operations.

Interim Source Removals

Many ISRs were conducted at the Site between 1990 and 2001. These activities have been summarized in a series of ISR memoranda (see Section 5 for references) and include the following:

- Areas 5 and 6 drum, soil, and debris removal

- Area 8 pipeline, tank, and soil removal
- Sympathetic detonations (Area 18)
- Dinitrotoluene (DNT)-impacted soil removal (Areas 10, 18, 25, and 31)
- Lead and miscellaneous debris removal (Areas 18/1/2/3/4, 19C, 24, 30, 31, 35, and 36, and Maintenance Buildings)
- Mercury-impacted soil removal (Area 39)
- Underground storage tank (UST) removals (Areas 20A, 20B, 38, and 39)
- Sitewide lead and arsenic hot spot removal including Area LR-68
- Lead- and arsenic-impacted soil removal around foundations and along the narrow-gauge railroad (NGRR)
- Lead- and arsenic-impacted soil removal (Sand Laydown Area)
- Lead- and arsenic-impacted soil removal (Topsoil Laydown Area)

Many of the pre-RI and RI sampling points were removed during the interim actions, and these data are no longer representative of current Site conditions. Therefore, all removed data points have been omitted from this RI.

Existing Conditions

Under current Site conditions, constituents of concern detected in Site soils at elevated concentrations are the following:

- Lead
- Arsenic
- Total petroleum hydrocarbons (TPH) (Bunker C and non-Bunker C)
- Mercury
- Trinitrotoluene (TNT)
- Benzo(a)pyrene

Other constituents have been detected in soil but, just because a constituent is detected does not mean it is above levels of concern.

Lateral and Vertical Extent

The lateral extent of the constituents detected in Site soil and debris was generally limited to production foundations and waste disposal areas, with the exception of lead and arsenic, which were also detected Sitewide, at concentrations above or near background soil concentrations. The vertical extent of constituents was generally confined to a depth of less than 1 foot in all areas except acid discharge areas, drywell locations, some production-related foundations, and disposal areas, where the vertical extent was generally limited to a depth of less than 10 feet.

EXECUTIVE SUMMARY

SITE GEOLOGY

The major stratigraphic units located beneath the Site are described in Section 3 and summarized in this section.

Steilacoom Gravels constitute the surficial soils of the Site and extend to a depth of about 300 feet. The Steilacoom Gravels consist of brown and gray stratified sands and gravels, with cobbles and occasional zones of siltier sand. The Steilacoom Gravels were deposited during the retreat of the final (Vashon) glaciation in high-energy meltwater channels. Below the Steilacoom Gravels is the Vashon Till.

The Vashon Till consists of a high-density, high-silt-content till that makes it a weak aquitard. The Vashon Till is underlain by the Vashon Advance Outwash, deposited by glacial rivers or streams during the advance of the Vashon glaciation. The Advance Outwash becomes finer grained with depth, typical of advance outwash deposition. Below the Advance Outwash is the Olympia Beds/Possession Drift/Whidbey Formation/Double Bluff Drift sequence (hereafter referred to as the DBD-OB sequence) (formerly known as the Kitsap Formation).

The DBD-OB sequence is a fine-grained, interglacial deposit, approximately 70 to 100 feet thick, and very heterogeneous regionally. The DBD-OB sequence is present below the Site but does not extend west of a line about 2,500 feet inland from Puget Sound. Below the DBD-OB sequence is the Salmon Springs Glaciation (formerly know as the Salmon Springs Formation), which was deposited in the glacial period preceding the DBD-OB sequence interglacial. Regional information indicates that the formation is 70 to 120 feet thick and contains zones of organic silt and till. The Sea Level Aquifer, a regionally extensive aquifer, occurs within the Salmon Springs Glaciation.

SITE HYDROGEOLOGY

Two aquifers occur beneath the Site—the shallow Water Table Aquifer extends from 20 to 105 feet below ground surface and the deeper Sea Level Aquifer is located between 160 and 215 feet below ground surface. Across most of the Site, the relatively impermeable Aquitard (formerly known as the Kitsap Aquitard) restricts vertical flow of groundwater and separates the Water Table Aquifer from the deeper Sea Level Aquifer. This aquitard is absent west of the "Cutoff" (formerly known as the Kitsap Cutoff), which is located 500 to 2,500 feet east of Puget Sound and roughly parallel to the shoreline. The "Cutoff" is the western extent of the Water Table Aquifer and the point at which the Sea Level Aquifer becomes unconfined. Groundwater in the Water Table Aquifer flows west-northwest, with local discharge via springs to upper Sequalitchew Creek. Groundwater in the Sea Level Aquifer flows west-northwest and discharges west of the "Cutoff" as seeps to Puget Sound.

GROUNDWATER QUALITY

Based on the groundwater data presented in the 1994 Draft RI report, Ecology issued a "No Active Remedial Action" letter for Site groundwater (Ecology 1996a). Long-term monitoring for DNT continues.

DNT Data for Site Groundwater

Data from 35 rounds of combined pre-RI and RI groundwater sampling at up to 30 locations (October 1988 through March 2001) indicate the consistent detection of DNT concentrations at marginally elevated concentrations in 6 of 30 Site groundwater monitoring locations. DNT has been detected inconsistently in one additional groundwater monitoring well at marginally elevated concentrations. If detected, the range of total DNT concentrations in groundwater is from 0.019 *u*g/L to 0.78 *u*g/L. DNT has been detected only in monitoring wells located downgradient of areas where DNT has been detected at elevated concentrations in soils (Areas 5, 18, and 31). The DNT groundwater concentrations are expected to decline over time as a result of the removal of DNT-containing soils. Based on ISR work and well data, Ecology determined that "no active remedial action" was needed and long-term monitoring at selected wells would be sufficient (Ecology 1996a).

DNT Data for Groundwater Discharging via Seeps to Puget Sound

The two seep sampling locations (Figure 3.1-1) represent discharge of Site groundwater to the intertidal area of Puget Sound. This groundwater discharge is naturally saline due to salt water intrusion, which disqualifies it as a drinking water source in accordance with MTCA. Total DNT concentrations have ranged from nondetect to 0.27 µg/L in the 25 samples collected from SEEP 1 over the period of monitoring. DNT has not been detected in SEEP 2. All detected DNT concentrations at SEEP 1 have been at least 33 times lower than the protective surface water concentration of 9.1 µg/L. Based on this comparison, DNT in groundwater discharging from the Site via seeps to Puget Sound poses no concern to human health or the environment.

Other Constituents

In 1988, nitrate was detected in three of the Site monitoring wells. Because one of these three monitoring wells is located along the eastern (upgradient) edge of the Site, off-Site sources of nitrate (such as animal pasturing) are possible. All three wells have had relatively low nitrate concentrations since 1988. Total carcinogenic polycyclic aromatic hydrocarbon (cPAH) concentrations in groundwater have all been low. With the exception of concentrations of naturally occurring aluminum (detected in background groundwater samples), all other dissolved metals were detected at low concentrations. No other constituents of concern that were analyzed for have been detected in Site groundwater.

SURFACE WATER FEATURES

Three surface water bodies—Puget Sound, Sequalitchew Creek, and Old Fort Lake—are located within or adjacent to the Site. Puget Sound is a large saltwater body located along the western boundary of the Burlington Northern property west of the Site. Puget Sound directly or indirectly receives all groundwater and surface water discharge from the Site. Sequalitchew Creek is a perennial stream that originates in Sequalitchew Lake east of the Site and discharges into Puget Sound. In the dry season, the upper and lower reaches of the creek within the Site are dry. Old Fort Lake is a small glacial kettle lake that has no inlet or outlet. The lake is fed by groundwater from the Water Table Aquifer, and the lake level is an expression of the Water Table Aquifer.

SURFACE WATER AND FRESHWATER SEDIMENT QUALITY

Surface Water

Constituents detected at elevated concentrations in Sequalitchew Creek and Old Fort Lake are consistent with those detected at the area background (upstream) sampling location in Sequalitchew Creek (SW-4, Figure 3.1-1) and in other rivers and streams in Pierce County.

Freshwater Sediment

None of the wide range of constituents analyzed for in sediment samples was detected at elevated concentrations. Lead was detected in Old Fort Lake sediments at low concentrations. Detected concentrations of other metals were comparable to available background freshwater sediment data for the Puget Sound region.

Based on the data presented in the 1994 Draft RI report, Ecology verbally agreed to No Further Action for all surface water and freshwater sediments within the CDB at the Site (Ecology 1996d).

Additional soil samples, groundwater samples, surface water and freshwater sediment samples, and marine sediment samples were collected outside the CDB. These data will be presented in a separate report.

E Data Quality Assessments

ABBREVIATIONS AND ACRONYMS

AA	atomic absorption
ACM	asbestos-containing material
ACTIVE	Active Construction
AP	area of potential concern
AST	aboveground storage tank
ATI	Analytical Technologies Inc.
CAP	Cleanup Action Plan
CDB	Consent Decree Boundary
cm/sec	centimeter per second
cPAHs	Carcinogenic polycyclic aromatic hydrocarbons
DERS	DuPont Environmental Remediation Services
DNB	1,3-dinitrobenzene
DNT	dinitrotoluene (includes 2,4-DNT and 2,6-DNT)
DuPont	E.I. DuPont de Nemours and Company
Ecology	Washington Department of Ecology
EIS	environmental impact statement
EM	electromagnetic
EPA	U.S. Environmental Protection Agency
ESM	ESM Consulting Engineers, LLC
FS	feasibility study
gpm	gallon per minute
ISD	inorganic solid debris
ISR	interim source removal
LDR	land disposal restrictions
LR	lead reference
µg/L	microgram per liter
µm	micrometer
mg/kg	milligram per kilogram
mg/L	milligram per liter
MMAN	monomethylamine nitrate
msl	mean sea level
MTCA	Model Toxics Control Act

NAX	nitroaromatic explosives (includes TNT, 2,4-DNT, 2,6-DNT, NB, DNB, and TNB)
NB	nitrobenzene
ncPAHs	noncarcinogenic polycyclic aromatic hydrocarbons
NFA	no further action
NG	nitroglycerin
NGRR	narrow-gauge railroad
OC	organochlorine
OP	organophosphorus
PAHs	polycyclic aromatic hydrocarbons, also called polynuclear aromatic hydrocarbons
PCB	polychlorinated biphenyl
PID	photoionization detector
PVC	polyvinyl chloride
RA	risk assessment
RI	remedial investigation
RU	remedial unit
SLA	sand laydown area
SVOC	semivolatile organic compound
TCLP	toxicity characteristics leaching procedure
TDS	total dissolved solids
TNB	1,3,5-trinitrobenzene
TNT	2,4,6-trinitrotoluene
TOC	total organic carbon
TPH	total petroleum hydrocarbons
TSS	total suspended solids
UST	underground storage tank
VOC	volatile organic compound
Weyerhaeuser	Weyerhaeuser Company
WRECO	Weyerhaeuser Real Estate Company
XRF	x-ray diffraction

This section summarizes the site history, site location and physical setting, the objectives of the Remedial Investigation (RI) report, the objectives of the field investigations, and the report organization. Much of the previous investigation work conducted at the Site is summarized in the pre-RI Phase I and Phase II reports (Hart Crowser 1986 and 1987, respectively). Pre-RI work is defined as any site investigation work done prior to the start of the formal RI agreed to in the 1991 Consent Decree. It includes any sampling activities that occurred prior to 1992. The management plans for this work are provided in the RI/Feasibility Study (FS) Management Plan (Hart Crowser 1992a). Previous reports and studies are referenced or briefly summarized where appropriate.

1.1 SITE LOCATION AND PHYSICAL SETTING

The Site is located in southwestern Pierce County, within the City of DuPont. The 636-acre Parcel 1 area within the Consent Decree Boundary (CDB) is the location of the Former DuPont Works (DuPont). Parcel 1 is bordered by the Weyerhaeuser Company (Weyerhaeuser) property to the north and west, and Weyerhaeuser Real Estate Company (WRECO) property to the east and south (Figure 1-1). Burlington Northern Railroad property is adjacent to Weyerhaeuser open space to the west. Puget Sound is located to the west of the Burlington Northern Railroad property. The Parcel 1 area within the CDB is referred to as the "Site" throughout the remainder of this document.

The Site is situated on a glacial outwash plain that slopes gently to the west, toward Puget Sound. The significant features of relief across the Site are numerous glacial kettles (depressions), the east-west-trending valley of Sequalitchew Creek, a small kettle lake in the southern portion of the Site (Old Fort Lake), and the steep bluff on the west. The elevation across the Site generally ranges from 200 to 225 feet above mean sea level (msl), except within the kettles, which are at an elevation of approximately 150 feet msl. The Site is generally partially cleared or forested, with intermittent clearings.

1.2 PROPERTY HISTORY

The Site property was originally used by Native Americans. European settlement began in 1832, when the Hudson Bay Company established a cabin/storehouse on nearby Puget Sound at the mouth of Sequalitchew Creek, northwest of the Site (City of DuPont 1995). In 1833, the Hudson Bay Company built Fort Nisqually in an area in the northern portion of the Site. Ten years later, Fort Nisqually was rebuilt at a location adjacent to but outside the eastern edge of the Site.

DuPont acquired the Site in 1906 and constructed an explosives plant. The historical village of DuPont, Washington, is approximately 1 mile southeast of the Site. DuPont continued to manufacture explosives until the mid-1970s, when it ceased operations and sold the Site and adjacent areas to Weyerhaeuser. Weyerhaeuser and its subsidiary WRECO still own the majority of the approximately 2,500 acres in the area known as Northwest Landing. Northwest Landing is a planned community within the City of DuPont and it includes the Site. WRECO has begun to develop Northwest Landing on some of its lands within the City, but no development of the Site has occurred.

1.3 REGULATORY HISTORY

The Site was used for the manufacture of commercial explosives from 1909 to 1976. Production of explosive materials ceased and decommissioning of the buildings began in 1976. As part of the decommissioning process, asbestos was removed, salvageable materials were taken out, and many structures were either burned or demolished. Actions taken at the Site subsequent to the shutdown in 1976 include the following:

- In 1985, Weyerhaeuser initiated studies to determine whether hazardous substances were present.
- In 1986, a Phase I Site Survey and Review was conducted to identify areas of the Site that may be of environmental concern.
- In 1986, soil contamination was first documented and reported to the Washington State Department of Ecology (Ecology).
- In 1987, a Phase II Site Characterization study was performed, which characterized the type, concentration, and distribution of constituents at 38 areas on the Site.
- In 1989, a Baseline Human Health Risk Assessment (RA) was performed using results of the Phase II survey.
- In 1991, Weyerhaeuser and DuPont signed a Consent Decree (No. 91 2 01703 1) with Ecology, in which they agreed to study the Site and complete an RI, RA, and FS. The Site was divided into two main areas: Parcel 1 (approximately 636 acres) and Parcel 2 (approximately 205 acres).
- In 1994 and 1995, Draft RI, RA, and FS reports were submitted to Ecology and underwent public review.
- In 1996, based on the result of interim source removal (ISR) actions, Ecology approved a Cleanup Action Plan (CAP) for Parcel 2 that provided for no further remediation activities except for the institutional controls to maintain the industrial use of Parcel 2.
- In 1997, Parcel 2 was deleted from the Consent Decree, and the deed requiring institutional controls to maintain the industrial use of the parcel was recorded in the Pierce County Assessor's office.
- Between 1990 and 2001, while studies and negotiations were ongoing, Weyerhaeuser and DuPont undertook ISR actions to clean up soil and/or debris at the Site, in accordance with the Model Toxics Control Act (MTCA) and the Consent Decree.

1.4 REMEDIAL INVESTIGATION REPORT OBJECTIVES

The purpose of the RI was to collect, develop, and report sufficient information regarding the Site to enable the completion of the RA and FS. The RI characterizes the nature and extent of contamination in the context of past activities at the Site. The RI report presents the analytical data for the media that have been collected at the Site. The data are presented for each RI area (Figure 1-2), as defined on the basis of historical manufacturing and production operations at the Site.

This RI summarizes the results of soil, groundwater, surface water, and sediment investigations conducted within the CDB. These investigations were conducted in accordance with the RI Management Plan (Hart Crowser 1992a). The Management Plan included an evaluation of locations outside of the CDB. The results of these investigations are or will be the topic of additional reports. In addition to the sampling specified in the RI Management Plan, soil verification data following ISRs and additional characterization data were collected in selected areas within the CDB.

The scope of the Site RI includes sample collection, laboratory analyses, data evaluation, and presentation of sampling results from four environmental media, as follows:

- 21,933 soil sample analyses (5,182 samples)
- 1,181 freshwater sediment sample analyses (20 samples)
- 12,038 groundwater sample analyses (283 samples)
- 1,528 surface water sample analyses (344 samples)

Because of the number and extent of interim actions conducted, many of the pre-RI and RI sampling points were removed during these activities and are no longer representative of current site conditions. Only those data representing current Site conditions within the CDB are included in this RI report. Samples excavated during ISR were removed from the RI database and were not used to characterize the Site.

The historical areas identified in the Consent Decree for further investigation and addressed in this document include the following:

- Area 1—Nitroglycerin Wash Water Gutter
- Area 2—Nitroglycerin Spill at No. 2 Nitrating and Separating House
- Area 3—Nitroglycerin Spill Along Gutter Line
- Area 4—Lead Residual at No. 2 Nitrating and Separating House
- Area 5—DNT Waste Drum Area
- Area 6—Crystallizer Drum Area
- Area 7—Waste Drainage Pit (Old Salt Lake)
- Area 10—Aluminum Water Gel Area
- Area 11—Water Gel Wash-Up Waste Pit Area
- Area 12—Works Magazine Landfill
- Area 16—Kettle Beneath Area 5
- Area 18—Nitroglycerin Production and Powderline Area
- Area 24—Upper Powerhouse
- Area 25—Acid Production Area
- Area 26—Waste Acid Recovery Area and Kettle
- Area 31—Burning Ground

- Area 38—Box Production Area and Drywell

The Consent Decree also identified Area 40, the Black Powder Area; however, as discussed previously, this area (also known as Parcel 2) has already been cleaned up and is no longer part of the Consent Decree process. For the purposes of the RI, Areas 1 through 4 and Area 18 have been combined into Area 18/1/2/3/4 to facilitate soil quality characterization.

The following seven areas were also identified as areas within the CDB for further investigation, based on additional historical information review.

- AP-A—Powder Test Ground
- AP-B—Smokeless Powder Dump (Phase II—Site 22)
- AP-C—Smokeless Powder Nitrating/Grinding House
- AP-D—Asphalt Paint Building
- AP-E—Main Transformer House
- AP-F—Nitrocotton Area (Drying House and Bunkers)
- AP-G—Decontamination Areas (Phase II—Site 23)

Three additional areas (Site Reference Area, LR-68, and narrow-gauge railroad [NGRR]) were identified for further study during the RI field activities. In addition to the areas identified above for RI evaluation, historical Site areas and miscellaneous Sitewide hot spot areas (Areas 1, 2, 3, 4, 5, 6, 8, 10, 18, 19, 20, 25, 26, 30, 31, 35, 36, 38, 39, and others), were approved by Ecology for ISR. Areas 15 and 32 have had early independent cleanup actions completed. ISR activities are discussed in Section 2.20. Table 1-1 summarizes the above information.

Specific objectives associated with the RI characterization phase of the project included the following:

- Determination of the lateral and vertical distribution of soil contamination within the RI areas
- Evaluation of the distribution and concentrations of constituents in Site groundwater, surface water, and freshwater sediments
- Refinement of the Site hydrogeologic conceptual model of the multi-aquifer groundwater system
- Determination of aquifer properties and groundwater flow rates
- Determination of representative area background concentrations for the Site soil and groundwater

1.5 FIELD INVESTIGATIONS

Pre-RI field investigations are summarized in the Phase I and Phase II Site Characterization Reports (Hart Crowser 1986 and 1987, respectively). The studies summarized in this report were conducted for Weyerhaeuser and DuPont between 1987 and September 2001. Studies performed after 1992 were conducted in accordance with the RI/FS Management Plan (Hart Crowser 1992a). Studies completed prior to 1992 where done using standard professional practices. The

Management Plan was prepared in consultation with Ecology, the public, and other participating agencies, in accordance with the following process:

- The Draft Management Plan (Hart Crowser 1992a) was reviewed by Ecology and revised in accordance with Ecology's comments between August 1991 and January 1992.
- The Draft Management Plan was available for public review between December 1991 and January 1992.

Field investigations conducted to meet the specific objectives stated above include:

- Surficial and deep soil sampling and analysis in 24 production-related areas
- Systematic sampling of soils outside of the production-related areas
- Water level measurements and surface water and freshwater sediment sampling and analysis in two surface water bodies—Sequalitchew Creek and Old Fort Lake
- Water level measurements, aquifer testing, and groundwater sampling and analysis for the Water Table and Sea Level Aquifers, including sampling and analysis of discharge at springs
- Area background soil and groundwater sampling and analysis

1.6 REPORT ORGANIZATION

Subsequent sections of this RI report are organized by medium—soil quality characterization by area (Section 2), groundwater characterization (Section 3), and surface water and freshwater sediment characterization (Section 4). Section 5 consists of a list of references cited in the report. Following the text are supporting tables and figures. All figures and tables were developed on the basis of information provided to URS in an analytical database submitted in final form for this RI on April 1, 2002 (Pioneer 2002). Appendices contain a discussion of field procedures and field exploration logs (Appendix A); soil quality data tables (Appendix B); and groundwater, surface water, and freshwater sediment quality data tables (Appendix C). Appendix D includes grain size distribution data for soil samples collected during the RI. Appendix E includes the data quality assessments for all data.

This section presents the findings of the RI soil characterization efforts at the Site. Information provided for each area in Sections 2.4 through 2.20 varies depending on the complexity of the area and the number and extent of detected constituents. Appendices A and B present field procedures and soil quality summary tables, respectively.

2.1 SITEWIDE SOIL CONDITIONS

Steilacoom Gravels constitute the surficial soils of the Site. The Steilacoom Gravels consist of brown and gray stratified sands and gravels, with cobbles and occasional zones of siltier sand. The Steilacoom Gravels were deposited during the retreat of the final (Vashon) glaciation in high-energy meltwater channels, which originated in a proglacial lake located in the present-day Puyallup River valley to the east (Walters and Kimmel 1968).

Over much of the eastern and central portions of the Site, the thickness of the Steilacoom Gravels typically ranges from 20 to 40 feet in these glacial meltwater channels. Along the western margin of the Site, the outwash channels feed into a large glacial delta (Sequalitchew Delta) within which the Steilacoom Gravels are more than 300 feet thick (extending below sea level). Cross-bedded gravel layers are commonly observed to dip toward Puget Sound within these deltaic deposits in the western portion of the Site.

Soil horizons developed on top of the Steilacoom Gravels consist of dark brown to dark gray, gravelly, sandy loam with variable percentages of organic matter and volcanic ash (Spanaway and Everett Series; Anderson et al. 1955). These soil horizons range in thickness from a few inches to approximately 3 feet depending on topography and vegetation. Soils developed on the geologic kettle floors include layers with higher silt and organic contents, indicating that the depressions may have been periodically flooded since the retreat of the Vashon glaciation, creating alternately dry and marshy conditions.

2.2 AREA BACKGROUND SOIL QUALITY

Twenty RI soil samples (BG-501 through BG-520) and three pre-RI soil samples (BG-SS-2, BG-SS-3, and BG-SS-5) were collected from outside of the CDB to define "Site area background" soil quality in accordance with MTCA. The majority of samples were obtained from locations to the south and east. Three samples were obtained from the coastal bluff to the north of the Site, as shown in Figure 2.2-1. The samples were positioned in locations that (1) have the same basic characteristic as Site soils, (2) have not been influenced by releases from the Site, and (3) have not been influenced by releases from other localized human activities, in accordance with WAC 173-340-709(2). Sampling locations were chosen to minimize the potential influence of airborne particulates settling on Site soils.

The Site area background soil samples were collected from undisturbed vegetated areas, with no apparent anthropogenic influences. The upper 6 inches of soil were composited after scraping away 1 to 4 inches of forest duff from the surface. Soils were generally described as moist, brown to black, silty, gravelly sand and are typical of the soils developed on top of the Steilacoom Gravels. Site area background soil samples were analyzed for the full list of parameters analyzed in on-Site soil samples, including 14 metals, polycyclic aromatic hydrocarbons (PAHs), nitrates, nitroaromatic explosives (NAX), nitroglycerine (NG), monomethylamine nitrate (MMAN), total petroleum hydrocarbons (TPH), semivolatile organic

compounds (SVOCs), volatile organic compounds (VOCs), polychlorinated biphenyls (PCBs), and organochlorine (OC) and organophosphorus (OP) pesticides. Ten additional samples (BG-511 through BG-520) were collected from similar locations outside the CDB and analyzed only for arsenic (Figure 2.2-1).

2.2.1 Summary of Results

A summary of Site area background soil quality is presented in Table 2.2-1. Metals, which are common and natural components of soil minerals, were the primary constituents detected. Nitrates, which are also naturally occurring, ranged from 0.8 to 4.2 mg/kg and averaging 2 mg/kg.

Organic Constituents

Low concentrations of three PAHs (acenaphthene, benzo(a)pyrene, and chrysene) were detected in at least one sample. PAH compounds are found in natural environments as a result of wood decay, forest fire, or other natural causes (Howard 1990). The presence of PAHs in area background samples does not diminish the samples' suitability or representativeness. In studies of background soil quality in rural areas (Harper-Owes 1985; Boyce and Michelsen 1993), PAH compounds were reported in a majority of soil samples at concentrations comparable to those reported in the Site area background samples (i.e., hundredths to tenths of one part per million).

Bis(2-ethylhexyl)phthalate, a common laboratory contaminant, was detected in three samples at concentrations close to or below the detection limit. No other VOCs or SVOCs were detected above their respective detection limits. No TPH, NAX, NG, MMAN, PCBs, or pesticides were detected in the Site area background samples. Based on the absence of organic anthropogenic constituents in the soil analyses, this set of samples is appropriate for defining area background quality in the vicinity of the Site.

Metals

Of the 14 metals tested (priority pollutant metals plus aluminum), thallium was not detected in any of the background samples; selenium was detected in only 1 sample; and mercury was detected in 3 of the 10 samples. The other metals were detected in all or a majority of the samples. Three background samples collected during the pre-RI produced comparable values for five of these metals (aluminum, antimony, chromium, lead, and zinc), and these three samples are included in the evaluation of background soils.

2.2.2 Comparison With Regional Background Soils

Metals concentrations for the Site area background soils were compared with regional background concentrations from Puget Sound (Ecology 1994). This Ecology background study did not address four metals (antimony, selenium, silver, and thallium). For these metals, other available references were used (Harper-Owes 1985; METRO 1985; Shacklette and Boerngen 1984). The 90th percentile concentrations of metals in the Site area background soils were calculated for comparison purposes. It should be noted that for several metals, only 11 of 14 samples were available; however, the data distributions were lognormal except for selenium and thallium, which had mostly censored data. The 90th percentile Site area and Puget Sound regional background concentrations are compared in Table 2.2-2.

The majority of metals exhibit comparable 90th percentile concentrations between the Site area background samples and Puget Sound regional background samples. The Site area background 90th percentile concentrations for five metals (antimony, arsenic, cadmium, lead, and mercury) are above the regional 90th percentiles. The 90th percentile arsenic concentration in Site area background samples (33 mg/kg) is above the 90th percentile arsenic concentration of 7.3 mg/kg reported for the Puget Sound (Ecology 1994). Ecology has accepted this value for arsenic as being representative of area background even though it is above MTCA Method A and B levels. The 90th percentile lead concentrations in Site area background samples (52 mg/kg) is above the 90th percentile lead concentration of 24 mg/kg reported for the Puget Sound (Ecology 1994).

The 90th percentile concentrations for antimony and mercury for the Site area background samples are also above the 90th percentile regional values. The Site area background 90th percentile concentration for cadmium is marginally above the Puget Sound regional value.

The 90th percentile concentrations for aluminum, beryllium, chromium, copper, nickel, selenium, silver, zinc, and thallium for the Site area background samples are equal to or less than the 90th percentile Puget Sound regional background concentrations.

2.3 INTRODUCTION TO AREA-SPECIFIC SOIL QUALITY

Sections 2.4 through 2.19 present the soil quality information collected for each of the RI areas and areas of potential concern (APs). Each area-specific section includes the history of activities, subsurface conditions encountered, and constituents detected in soils. It should be noted that just because a constituent is detected in soil does not mean that it is above levels of potential concern. Section 2.20 presents a summary of the results from ISR actions. The purpose of this section is to present current Site data. Sample analytical results were not compared to regulatory criteria in this RI. The current analytical data set for soil quality analyses for each area (pre-RI, RI, additional characterization samples, and ISR verification samples), including detection limits, is presented in Appendix B.

Validated analytical results from the RI project laboratories were used. Duplicate analyses were excluded. During Site work, nearly 1,000 field screening analyses were collected for dinitrotoluene (DNT) (Modified EPA Method 8090), TPH, arsenic and lead (x-ray diffraction [XRF]). Good correlations were established between the screening results and laboratory confirmation results for each constituent except arsenic (XRF interference). In all cases, the screening data were used only for field characterization and ISR work and were not retained in the database developed for this RI (Pioneer 2002).

Pre-RI characterization data were included if these data were of sufficient quality. Pre-RI data that were excluded from the Site database are the following:

- Oil and grease data (EPA Method 413.2) due to the nonspecificity of the analytical methods (i.e., this method measures natural oils and greases in addition to petroleum constituents)
- Selected PCB and PAH data due to insufficient detection limits
- Samples composited from greater than 5-foot vertical intervals
- Samples that could not be accurately relocated in the field based on field evidence (e.g., staking, flagging, or pre-RI exploration plans [pre-RI locations were not surveyed])

Although selected area soil samples were analyzed for potential metals leachability using the toxicity characteristics leaching procedure (TCLP), all of these sampling locations were excavated during the 2000 ISR, with the exception of one sample in Area 26 (addressed in the RA and FS). Therefore the TCLP analyses are not representative of current site conditions and are not discussed further in this RI.

One or more figures, showing sampling locations, are included for each area. Figure 2.3-1 is the legend for all the area-specific figures. In areas where ISR excavation or grading has occurred, depths for all samples (both pre- and postexcavation) within excavations less than 2 feet deep are referenced to the existing excavation grade. Depths for all samples (both pre- and postexcavation) within excavations greater than 2 feet deep are referenced to original (preexcavation) grade. Exceptions to this reporting convention are for Area 5, the Area 31 ravine, and all interim corrective actions that occurred after 1999. Depths for samples within these two areas are referenced to existing excavation grade. The depth assumptions used for data presentation in this report may not represent actual future elevations. References to samples collected at specific depths in boreholes are cited by the area in which they were collected, the type of collection method, and the sampling depth. For example, sample 7-B-503 represents "Area 7, borehole 5, sampled at 3 feet."

Borehole sampling locations are shown in a figure as 7-B-5 without an indication of the sampling depth. The individual samples and depths from each borehole are included in the soil quality tables provided in Appendix B.

Because of the number and extent of interim actions conducted, many of the pre-RI and RI sampling points were removed during these activities and are no longer representative of current Site conditions. Therefore, these data are not presented in the RI. All figures and tables were developed on the basis of information provided to URS in an analytical database submitted in final form for this RI on April 1, 2002 (Pioneer 2002).

2.4 AREA 6—CRYSTALLIZER DRUM AREA SOIL QUALITY

2.4.1 History of Activities

According to former DuPont employees, Area 6 was used for disposal of defective 55-gallon ammonium nitrate drums used at the ammonium nitrate plant.

2.4.2 Soil Conditions

During the excavation of a test pit in the center of the former ammonium nitrate plant foundation, a concrete slab was encountered approximately 3 feet below grade. Subsequently, test pit 6-TP-501 was relocated along the western edge of the foundation, where excavation to a depth of 10 feet was possible. At this location, fill containing demolition debris (e.g., bricks and mortar) was encountered to a depth of 5 feet. A 4-foot vertical length of 3-foot-diameter steel casing filled with soil was observed between depths of 1 and 5 feet. Along the northern wall of the excavation, the concrete foundation was observed to extend to a depth of 6 feet below grade. Below the concrete foundation, Steilacoom Gravels were encountered to a depth of 10 feet. Soils in 6-TP-501 were later excavated to a depth of 10 feet during ISR. Steilacoom Gravels

were also observed to a depth of 10 feet in 6-TP-502, located north of the foundation (Figure 2.4-1).

2.4.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 6 included eight total metals, TPH, and nitrate. Each of these analytes was detected in at least one sample from Area 6.

The RI soil quality data and associated sampling depths for Area 6 are summarized in Table B-1.1. Sampling locations are shown in Figure 2.4-1.

TPH concentrations in Area 6 range from 23 to 1,900 mg/kg. Results from the paraffin investigation (Hart Crowser 1996) indicated that the TPH in Area 6 was heavy oil-range petroleum, not paraffin.

ISR for this area is described in Sections 2.20.1 and 2.20.16.

2.5 AREA 7—WASTE DRAINAGE PIT (OLD SALT LAKE) SOIL QUALITY

2.5.1 History of Activities

This natural geologic kettle formation, defined as Area 7 and historically referred to as Old Salt Lake, received liquid and slurry wastes from the main powerhouse tank moats; oil residues from boilers, boiler blow down, and sewer drainage; and waste salts from the former nitric acid plant since the early 1900s. Waste materials were discharged via a subsurface pipeline to a swale leading into the south side of the kettle. Aerial photographs (1942 and 1961) indicate that liquid levels appear to have been near the upper limit of the kettle perimeter at various times in the past.

2.5.2 Soil Conditions

The general subsurface materials encountered within the Area 7 kettle consist of a fine-grained, non-native fill material overlying Steilacoom Gravels. The fill material consists of very light to dark gray silt- and clay-sized material mixed with variable percentages of sand, gravel, and wood fragments. The fine-grained material was observed to be finely laminated in some locations and interbedded with buried soil horizons (roots) in other locations, indicative of episodic fill deposition.

The fill material was observed to cover most of the kettle floor and much of the swale leading into the kettle from the south. The fill was not observed on the kettle walls or outside of the kettle. The fill thickness increased toward the kettle center, as was clearly observed in an observational test pit, 7-TP-501, excavated from the southern kettle wall toward the kettle center (Figure 2.5-1). Within the kettle bottom, the fill thickness was variable, typically extending to depths of 5 to 13 feet below grade, with a maximum observed thickness of 18 feet in 7-B-503.

Beneath the fill, Steilacoom Gravels were encountered to the depth of exploration below the kettle floor (75 feet in 7-B-503). Monitoring well MW-1, located immediately north of the Area 7 kettle (Figure 2.5-1), penetrated 220 feet of Steilacoom Gravels. The water table in the unconfined portion of the Sea Level Aquifer (Steilacoom Gravels) is at a depth of approximately 180 feet below grade at MW-1 (approximately 165 feet below the kettle bottom).

A thin discontinuous layer of weathered Bunker C residue (hardened tar-like material) occurred over more than half of the surface at the bottom of the kettle and over the lower portions of the kettle walls. The residue was not encountered more than approximately 4 to 6 inches below grade in any pre-RI or RI explorations. In addition, a viscous Bunker C oil staining occurred at the surface in the swale and in the southwestern portion of the kettle.

Green and yellow staining of the gravels was observed in all subsurface explorations within the kettle, except test pits 7-TP-502 and 7-TP-504, which were located along the lower kettle walls. A faint sulfur-like odor was also detected in subsurface samples (to 15 feet) of the fill material from the three RI borings within the kettle. This odor was generally not discernible in the open test pit excavations. Gravels at the surface in the kettle were typically bleached, pitted, and crumbly, indicating deterioration related to historical discharge of wastes from the acid production area. Gravels in the subsurface also showed signs of deterioration, although not to the same degree as the surficial fill materials.

2.5.3 Perched Water Occurrence

During drilling of RI boring 7-B-503 in July 1992, vertically discontinuous zones of perched water were encountered between depths of approximately 20 and 33 feet in Steilacoom Gravels underlying the fill material. However, in this boring and in others, no low-permeability soil units (e.g., silts), which would constitute a significant perching unit for groundwater, were observed within the Steilacoom Gravels.

In accordance with the Sampling and Analysis Plan (Hart Crowser 1992a), a monitoring well was installed within the zone of apparent perched saturation encountered in boring 7-B-503. During attempted well development the day after installation, the well bailed dry after one casing volume was removed, suggesting that the zones of saturation are discontinuous. Due to the lack of water level recovery, no significant well development could be achieved in the perched-zone well. Groundwater from the perched-zone monitoring well 7-B-503 was sampled after the well was bailed dry. The water bailed from the well was observed to be exceptionally turbid. Sufficient water was collected for analyses of total and dissolved metals, NAX, and PAHs. These data are discussed in Section 3.2. Monitoring well 7-B-503 was dry during the August 1992 round of water level measurements and in all subsequent rounds of water level measurements and groundwater sampling.

Saturated conditions were not encountered to a depth of approximately 29 feet during drilling of the RI borings 7-B-501 and 7-B-502 in February 1992. Zones of saturation were encountered in some of the pre-RI borings drilled to similar depths in December 1986 and April 1987. A piezometer installed in pre-RI boring 7-B-4 was dry within 1 week after its installation, indicating that the saturation is transient.

The observations from drilling in this kettle, and in the kettles in Areas 16 and 26 (discussed in Sections 2.9 and 2.12, respectively), indicate that zones of saturation beneath the kettles are transient and discontinuous (both laterally and vertically). The water observed during drilling may represent infiltrating wetting fronts rather than zones of true saturation. This would also be consistent with the lack of observed lower permeability layers (e.g., silts), which would act to perch infiltrating water.

2.5.4 Constituents in Soil

Laboratory analyses performed on soil samples from Area 7 included up to nine total metals, TPH (Bunker C), explosives, SVOCs, PAHs, pesticides, and PCBs. All of these analytes were detected in at least one sample from Area 7, except for explosives, which were not detected in any samples from this area.

The RI soil quality data and associated sampling depths for Area 7 are summarized in Tables B.2-1 through B.2-6 in Appendix B. Sampling locations are shown in Figure 2.5-1.

2.6 ISR FOR THIS AREA IS DESCRIBED IN SECTION 2.20.15. AREA 10—ALUMINUM WATER GEL AREA SOIL QUALITY

2.6.1 History of Activities

Interviews with former DuPont employees indicate that residual aluminum water gel (consisting of salts, nitrates, aluminum, and gelling agents) was reportedly buried in an area approximately 10 feet by 12 feet in Area 10. During pre-RI field work, two test pits were excavated and two soil samples were collected for analyses.

2.6.2 Soil Conditions

During the RI, three test pits (10-TP-501, 10-TP-502, and 10-TP-503) were excavated to a depth of 10 feet to confirm pre-RI results and assess the vertical extent of constituents. During the excavation of one test pit, approximately 1 dozen deteriorated water gel bags were observed in the top 2 feet. Some of the bags contained residual water gel. Scattered yellow spheroidal pellets (flake trinitrotoluene [TNT], according to a former DuPont employee) were observed in the sand. Two soil samples were analyzed for nitrate and aluminum; one sample was analyzed for TNT only; and one sample was analyzed for NG, DNT, and TNT.

2.6.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 10 included up to 14 total metals, explosives, SVOCs, and PAHs. Total metals, SVOCs, and explosives were detected in at least one sample from Area 10. The compound bis(2-ethylhexyl)phthalate, the only SVOC detected, was found in a single sample at a concentration near the detection limit and was therefore qualified. PAHs were not detected in any samples from Area 10. Elevated TNT (270 and 840 mg/kg) and DNT (3 mg/kg) concentrations were found. These locations were remediated during the 1999, 2000, and 2001 ISR efforts (see Section 2.20). SVOCs, NG, and lead were not detected in these pre-RI samples. Nitrate concentrations (3.0 and 3.4 mg/kg) were within the range of background concentrations.

The soil quality data, associated depths, and analytes for Area 10 are summarized in Tables B.3-1 through B.3-3 in Appendix B. Sampling locations are shown in Figure 2.6-1.

ISR work conducted in Area 10 is described in Sections 2.20.14 and 2.20.16.

2.7 AREA 11—WATER GEL WASH-UP WASTE PIT AREA SOIL QUALITY

2.7.1 History of Activities

Area 11 was used for disposal of water gel wash-up material and associated packaging materials. The disposal area, a shallow depression approximately 50 by 50 feet, was reportedly detonated as part of plant decommissioning prior to Weyerhaeuser's acquisition of the property. During pre-RI sampling, six plastic mesh bags about 2 feet long by 10 inches wide and containing a grayish powder were found on the surface. Fill materials encountered during excavation of six pre-RI test pits included a fine-grained material (possibly sawdust) with interbedded leaves and sticks.

Pre-RI sampling data from test pit 11-TP-6 indicated slightly elevated TNT concentrations. Concentrations of lead, nitrate, NG, and MMAN were not elevated.

2.7.2 Soil Conditions

One 28-foot boring (11-B-501) and four 10-foot test pits (11-TP-501 through 11-TP-504) were completed for the RI within and around the former disposal area to define the lateral and vertical extent of TNT and DNT and to assess the potential presence of other constituents. The boring was advanced at the approximate center of the shallow depression. Fill material observed during pre-RI sampling was not encountered during advancement of this boring or during excavation of the RI test pits. Steilacoom Gravels were encountered to the depth of exploration in all RI explorations. At 17 feet below ground surface, an approximately 1-foot zone of water was observed perched on a 2-foot layer of till-like material observed at a depth of 18 to 20 feet. This zone appears to be similar to the zone of groundwater observed perched on till during the drilling of monitoring wells MW-22/MW-27 to the north (refer to Section 3.1).

2.7.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 11 included up to 14 total metals, TPH, explosives, SVOCs, and PAHs. Total metals, TPH, and explosives were detected in at least one sample from Area 11. SVOCs and PAHs were not detected in any samples from this area.

The RI soil quality data, associated depths, and analytes for Area 11 are summarized in Tables B.4-1 through B.4-4 in Appendix B. Area 11 sampling locations are shown in Figure 2.7-1.

2.8 AREA 12—WORKS MAGAZINE LANDFILL SOIL QUALITY

2.8.1 History of Activities

Materials related to explosives packaging activities in the Works Magazine were reportedly buried in shallow excavations in several areas of the Works Magazine Landfill. Materials identified or reportedly buried (by former DuPont employees) include explosives packaging, auto shop wastes, empty ammonium nitrate drums, and residual water gel. Seven units of the landfill, designated 12-1 through 12-7, were identified in the pre-RI work. As discussed below,

Unit 12-4 was deleted from further evaluation because only native materials were observed in subsurface explorations.

A total of 29 pre-RI test pits were excavated to determine the presence or absence of buried materials and to provide soil samples from the units.

During pre-RI sampling in Area 12, elevated MMAN concentrations were found at one location each in Unit 12-1 (2,900 mg/kg), Unit 12-2 (1,000 mg/kg), and Unit 12-6 (30,000 mg/kg). Concentrations of other constituents in the pre-RI samples were not elevated.

2.8.2 Soil Conditions

During the RI, 5 soil borings and 24 test pits were completed within and around the former disposal units to define the lateral and vertical extent of MMAN and to assess the potential presence of other constituents in this area. Boring and test pit locations and approximate debris boundaries are shown in Figure 2.8-1. Debris fill was encountered at several explorations within the landfill units. Steilacoom Gravels were encountered in all explorations outside of the fill areas. Native soils from a gravel borrow pit located north of Unit 12-2 were used to cover debris in Units 12-1, 12-2, 12-3, 12-5, and 12-6.

Unit 12-1

Debris, including empty water gel bags and plastic and metal strapping, was observed in 6 of 10 test pits and in the one boring in this unit. Generally, debris extended from depths of approximately 2 to 6 feet and was covered on the surface by 1 to 2 feet of dark brown, gravelly sand. The fill materials area measured approximately 150 by 20 feet.

Unit 12-2

Debris was observed in all 18 test pits and in both borings in this unit. Generally, debris extended from depths of approximately 2 to 8 feet and was covered on the surface by 1 to 2 feet of dark brown, gravelly sand. Debris consisted of water gel bags, some with residual water gel, wooden posts, paraffin-coated cardboard boxes, railroad ties, asbestos-containing material, and other mixed solid waste (e.g., old truck tires, tin cans, plastic, foam rubber, and metal banding). All asbestos-containing material (ACM) was removed and disposed of at an approved landfill during the RI excavation by TLH Abatement Inc. Unit 12-2 is the largest of the units, and the fill materials area measured approximately 550 by 150 feet. Unit 12-2 is bounded on the north by a gravel borrow pit from which native soils were historically obtained for covering the landfill units.

Unit 12-3

Debris was observed in all six test pits excavated in this unit. Generally, debris extended from depths of approximately 2 to 6 feet and was covered on the surface by 1 to 2 feet of dark brown, gravelly sand. Debris included water gel bags with residual water gel, and plastic tubing. The fill materials area measured approximately 210 by 50 feet.

Unit 12-4

Unit 12-4 is a 10- by 200-foot depression that apparently was never filled. The depression may be a gravel borrow pit similar to the one north of Unit 12-2. Three test pits were excavated in this unit (Figure 2.8-1). No debris was observed during excavation of the pre-RI or RI explorations, or during an RI field reconnaissance. Therefore, Unit 12-4 was not evaluated further.

Unit 12-5

Debris was observed in all six test pits excavated in this unit. Generally, debris extended from depths of approximately 2 to 6 feet and was covered on the surface by 1 to 2 feet of dark brown, gravelly sand. Debris included packaging materials (pressed cardboard and plastic strapping). The fill materials area measured approximately 125 by 75 feet.

Unit 12-6

Debris was observed in three of five test pits, but not in the one soil boring in this unit. Generally, debris extended from depths of approximately 2 to 7 feet and was covered on the surface by 1 to 2 feet of dark brown, gravelly sand. Observed debris included white plastic tubing containing residual water gel, and other mixed solid waste (e.g., tin cans, ceramics, and glass jars). Based on test pit excavations, this unit appears connected to Unit 12-7.

Unit 12-7

Debris was observed in two of three test pits, but not in the one soil boring in this unit. Debris included white plastic tubing containing residual water gel, and cardboard. Based on test pit excavations of Units 12-6 and 12-7, the two units appear to be connected (as shown in Figure 2.8-1). Dimensions of the fill materials for this combined unit area are approximately 200 by 20 feet.

Inter-Unit Test Pits

Debris was observed in two of five test pits excavated between delineated landfill areas. Debris included empty water gel bags and mixed solid waste (e.g., logs, styrofoam, cardboard, and plastic banding). Both test pits containing debris (12-TP-501 and 12-TP-505) are located within redefined unit boundaries (Units 12-2 and 12-5, respectively) (Figure 2.8-1). All other inter-unit test pits contained only native material and thus do not appear to be associated with any landfill unit.

2.8.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 12 included up to 14 total metals, TPH, explosives, SVOCs, PAHs, pesticides, and PCBs. The TPH (Method 418.1) results were associated with paraffin-coated cardboard except in one location where automobile parts were observed (test pit 12-2-TP-9). Paraffin wax is generally regarded as biologically inert. Additionally, no carcinogenic PAHs (cPAHs) were detected in 22 samples analyzed from this area. All of these analytes were detected in at least one sample from Area 12, except for pesticides and PCBs, which were not detected in any samples from this area.

Tables B.5-1 through B.5-6 in Appendix B detail the RI soil quality data, associated depths, and analytes in Area 12. Figure 2.8-1 shows the sampling locations.

2.9 AREA 16—KETTLE BENEATH AREA 5 SOIL QUALITY

2.9.1 History of Activities

Area 16 encompasses the large natural geologic kettle beneath Area 5, referred to as the DNT Waste Drum Area. Former DuPont employees reported that the kettle received cooling waters and liquid wastes from the acid production area (Area 25) to the west and southwest. Historical aerial photographs indicate the kettle periodically contained water during plant operation. The liquids were discharged to the Area 16 kettle through a pair of pipes that daylighted near the top of the kettle walls. Erosional gullies formed beneath the pipe outfalls and extended down the kettle walls to the kettle floor. These gullies and surrounding soils were removed during the Area 5 ISR documented by Hart Crowser (1994c).

During pre-RI sampling in Area 16, elevated lead concentrations were found. To facilitate staging of the Area 5 ISR, the upper foot of soil was graded in the Area 16 kettle bottom following the first phase of RI soil sampling. The approximate limit of the graded area, which transitions into the Area 5 ISR excavation area on the west, is shown in Figure 2.9-1. RI soil borings 16-B-501 and 16-B-505 and surface samples 16-SS-504 through 16-SS-523 were completed after the grading. All depths in Tables B.6-1 through B.6-7 in Appendix B and in Figure 2.9-1 are referenced to the current grade.

2.9.2 Soil Conditions

The generalized sequence of soils encountered in the Area 16 kettle consisted of scattered fill materials overlying varying thicknesses of soil developed on Steilacoom Gravels. Most fill materials from the base of the Area 5 hillside were removed during the Area 5 ISR. Bunker C residue was observed as a thin discontinuous surficial layer over portions of the ungraded kettle bottom.

A veneer of finer-grained soils typically less than 4 feet thick occurred over much of the kettle bottom. Because finer-grained materials are continually being eroded and transported from the kettle walls down slope, the thickest accumulation of fine-grained soils was found in the kettle bottom rather than on the kettle walls.

Beneath the surficial soil veneer, the Steilacoom Gravels were encountered to the exploration depth of 75 feet in boring 16-B-501. On-site monitoring wells indicated that the sequence continues uninterrupted to below msl (to depths of over 200 feet outside of the kettle). Regional information indicates that the Steilacoom Gravels extend to more than 100 feet below msl, nearly 250 feet below the kettle bottom.

Data from the four monitoring wells surrounding the kettle (MW-2, MW-3, MW-4, and MW-5; see Figure 3.1-1) and the deep soil boring within the kettle bottom (16-B-501) indicate that the Area 16 kettle is located west of the "Cutoff" (formerly known as the Kitsap Cutoff), which is the western extent of the Aquitard (formerly known as the Kitsap Aquitard) and Water Table Aquifer, as discussed in Section 3.1. Although Area 16 is located west of the "Cutoff", the water table surface continues to slope relatively steeply beneath the kettle. A 30- to 40-foot drop in

water table elevation was observed from the east side (MW-4 and MW-5) to the west (MW-2 and MW-3) side of the kettle. Based on the elevation of the kettle bottom (140 to 145 feet), the water table lies 100 to 120 below the floor of the kettle basin.

Thin zones of saturation appear to exist in the shallow soils beneath the Area 16 kettle, but the saturation is transient and discontinuous (both laterally and vertically). Zones of silty sand were encountered within the stratified sands and gravels, but they are also laterally and vertically discontinuous. No continuous perching units (e.g., competent silts) were observed within the 75-foot-deep exploration beneath Area 16.

Wet soil samples were described in several intervals of the pre-RI and RI borings within Area 16. A piezometer screened between depths of 28 and 32 feet in pre-RI boring 16-B-4 contained water for a few weeks following its installation in spring 1987, suggesting a perched zone of saturation. However, the piezometer was dry during drilling of the RI soil borings in February 1992, following a period of relatively heavy rainfall. The tip of the water level sounder was wet following the measurements, suggesting the piezometer end cap had water in it at times. The piezometer was also dry during RI drilling in July 1992.

During drilling of the RI borings in February 1992, a few inches of water were observed in one of the three borings (16-B-504) between depths of approximately 9 and 14 feet. In borings 16-B-502 and 16-B-503, and at other depths in 16-B-504, samples were described in the field as wet, yet no standing water was measured in the borehole. This condition was also observed during drilling in the other two kettles (Area 7 and Area 26). In these cases, the wet samples may represent infiltrating wetting fronts rather than perched zones of saturation.

Boring 16-B-501, drilled in July 1992, was completed as a monitoring well to sample perched water if present, in accordance with the Sampling and Analysis Plan (Hart Crowser 1992a). No standing water was observed in the boring during drilling. The bottom of the well screen was set on a thin interval of silty sand; however, no water was observed in this well at the time of installation or in any of the subsequent rounds of groundwater sampling or water level measurements.

These combined observations, along with those from the other on-site kettles (Sections 2.5 and 2.12), indicate that perched water is not present beneath the kettles.

2.9.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 16 included up to eight metals, TPH (Bunker C), explosives, SVOCs, PAHs, pesticides, and PCBs. All of these analytes, except for SVOCs, were detected in at least one sample from Area 16. Endrin, detected in one sample, was the only pesticide detected. In addition, PCB-1254, detected in one sample, was the only PCB compound detected. SVOCs were not detected in any samples from this area. Based on site characterization results, detectable lead, barium, and chromium remain in this area.

Tables B.6-1 through B.6-7 in Appendix B provide a summary of the RI results and associated depths for Area 16. Figure 2.9-1 shows the sampling locations.

2.10 AREA 18/1/2/3/4—NITROGLYCERIN PRODUCTION AND POWDERLINE AREA SOIL QUALITY

2.10.1 History of Activities

This large area was used for the production of NG and dynamite. Area 18/1/2/3/4 encompasses the NG production area (Area 18 North and Area 1/2/3/4) and five dynamite production and packaging lines (Area 18 South), two cartridge dynamite lines, two gelatin dynamite lines (one of which was converted to water gel production in the 1960s), and one smokeless powder production line.

Area 18 North and Area 1/2/3/4 NG production facilities included nitrators, separators, and neutralizers. Two separate process lines (Nitrator No. 1, Separator No. 1, and a combined Nitrator/Separator House No. 2) were constructed between 1907 and 1909, along with associated Neutralizer House No. 1 and No. 2. A third separate process line consisting of Nitrator/Separator House No. 3 and Neutralizer No. 3 was added in 1915. Nitrator No. 1 and Separator No. 1 were burned as part of decommissioning in 1925; an explosion eliminated Combined Nitrator/Separator House No. 2 in 1938. A new facility was built over the remains of the original. The remaining facilities were burned during Site decommissioning between 1976 and 1977.

Area 1/2/3/4 includes the following specific sites:

- Area 1—NG Wash Water Gutter
- Area 2—NG Spill at No. 2 Nitrating and Separating House
- Area 3—NG Spill Along Gutter Line
- Area 4—Lead Residual at No. 2 Nitrating and Separating House

This area was investigated because of the potential for residual NG, lead debris, and wastewaters associated with NG production. As part of the production process, residual NG was settled out of the wash water during both the separating and neutralizing phases and reintroduced to the manufacturing process. Wash water (following NG settling) was then sent to a wash water gutter system (Area 1) that ran north of the combined nitrating/separating houses. In later years, wash waters, particularly from the neutralizers, were sent to seepage ponds adjacent to the individual facilities.

In the mid-1950s, a spill of approximately 300 pounds of NG occurred near the south steps of the No. 2 Nitrating and Separating House (Area 2). According to former DuPont employees, this spill was treated with sodium sulfide and later detonated during plant decommissioning. In 1961, approximately 100 to 200 pounds of NG were spilled from the NG gutter system (Area 3), and this area was treated with sodium sulfide and later detonated. Area 4 encompasses the debris resulting from decommissioning of the No. 2 Nitrating and Separating House, which contained lead sheeting.

The Powderline Area (18 South) included facilities to mix dynamite ingredients, pack cartridges, and box finished products. Facilities including mixing houses (in the central portion of Area 18), cartridge houses, and packing houses, followed a process line organization. Three lines were initially developed south of the NG area: two for cartridge dynamite (talley mix) and one for gelatin dynamite. The gelatin line ran along the eastern edge of the area. A fourth line, also for

gelatin, was added to the west in 1915. By the 1950s, the fourth line and one of the talley mix lines had been eliminated. The eastern line served for DNT gelatin production and subsequently was converted to water gel production in the 1960s.

The nitrostarch/smokeless powderline was constructed west of the other powderline facilities in 1916. It included four storehouses, four drying houses, a screening house, and a nitrating house. The facilities were converted in 1923 to reprocess surplus cordite and smokeless powder that had been returned by the U.S. military. The powder was reground to manufacture blasting compounds for farm use (sodatol and pyrotol). The reprocessing was completed in 1927. The buildings were burned during decommissioning in 1931.

Materials reportedly handled or present at these facilities include waste acid (with trace amounts of NG), lead, NG, MMAN, DNT, TNT, and nitrostarches. Lead linings, washtubs, and pipes were commonly used in the foundations of production facilities to contain process liquids or spills and reduce accidental sparking.

During the pre-RI site characterization, 101 samples were collected for constituent testing from 69 test pits and 9 hand augers in Areas 1, 2, 3, 4, and 18. Additional test pits were excavated for characterization of subsurface conditions. Constituent analytical results indicated elevated lead concentrations. TNT, DNT, and NG concentrations were not elevated. Aside from common laboratory solvents, VOCs were generally not detected. Subsequent to the pre-RI site characterization, many of these sampling points were removed during ISR and are no longer representative of current site conditions.

2.10.2 Soil Conditions

A variety of fill layers and non-native materials were observed in test pits from this area. Fill soils are generally composed of slightly silty, sandy gravel and gravelly sand—essentially regraded, local Steilacoom Gravels. Many of the production facilities had been bunkered by sloping berms of fill soil built up against the foundation walls. In addition, a variety of non-native materials (e.g., timbers) are mixed into fill soils.

Lead

Lead debris was observed at the surface or uncovered in the subsurface at several localities (at test pits 4-TP-2, 4-TP-7, 18-TP-16, 18-TP-32, and 18-TP-37; surficial soil from 4-TP-2, 4-TP-7, and 18-TP-37 was removed during ISR). Intact, 1/8-inch-thick lead sheeting over concrete floor pads was also observed (test pits 4-TP-8, 18-TP-17, and 18-TP-18; surficial soil in all three of these locations was removed during ISR). Most of this elemental lead was observed in the nitrators and neutralizers and has since been removed during ISR of lead debris.

Washwater Gutters

A buried concrete gutter was observed in a series of test pits that were originally designated as Area 1 (1-TP-6 through 1-TP-11). The gutter and an associated lateral gutter system carried residual process wash waters from the separators and neutralizers. The gutters were wood-covered troughs, concrete structures approximately 1 foot-wide and lined with tar. They led to a filtering house before wash waters were discharged to the ground in the vicinity of a 5-foot-deep depression at the western end of the main gutter. Most of the wash water system was no longer used after the 1950s, and subsequent site activities buried the gutters beneath 1 to 5 feet of fill.

Potential Asbestos-Containing Materials (ACM)

Where lead-lined floors were observed in the old foundations, the lead sheeting was sometimes separated from the concrete pad by a thin layer of potential ACM (4-TP-8 and 18-TP-18). Elsewhere, potential ACM was associated with metal ductwork (18-TP-550 and 18-TP-553) and shingles (18-TP-2). Potential ACM fragments were also noted with demolition debris in a number of explorations (18-TP-1, 18-TP-9, 18-TP-23, 1234-TP-503, and 18-TP-534). The top foot of soil was later excavated from locations 18-TP-534 and 18-TP-23 during ISR. Materials suspected by the field personnel to be potential ACM were evaluated by the on-site asbestos abatement contractor, TLH Abatement Inc. Any materials confirmed to be ACM by TLH Abatement Inc. were handled and disposed of by TLH Abatement Inc. at an appropriate landfill.

DNT/TNT Residual

During the RI characterization work, residual DNT/TNT was identified near the DNT Heater and Melt Houses (south of Neutralizer Nos. 1 and 2), the Gelatin Mixing House No. 1, and the Dynamite Mixing House Nos. 1 and 2. As a result of these observations, a program to systematically locate and remove residual DNT/TNT was initiated in the central part of Area 18. Initially, a peripheral zone of surface soils surrounding the DNT Heater Houses and Mixing Houses was inspected for residual DNT/TNT by systematically scraping and exposing the upper few inches of soil cover with a bulldozer. Suspected residual DNT/TNT was field tested using a colorimetric indicator test. The scraping operations uncovered additional residual DNT/TNT locations, most within a 150-foot radius of these foundations.

2.10.3 Constituents in Soil

Laboratory analyses that were performed on soil samples from Area 1/2/3/4 included up to eight metals, explosives, VOCs, SVOCs, and PAHs. All of these analytes, except for SVOCs, were detected in at least one sample from Area 1/2/3/4. NG, detected in one sample, was the only explosives compound detected. SVOCs were not detected in any samples from this area.

Laboratory analyses that were performed on soil samples from Area 18 included up to eight metals, TPH, explosives, PAHs, and nitrate. All of these analytes were detected in at least one sample from Area 18. Many of these sampling points were removed during ISR and are no longer representative of current site conditions.

The RI and ISR verification data for Area 18 and Area 1/2/3/4 are summarized in Tables B.7-1 through B.7-6 in Appendix B. Figure 2.10-1 shows the sampling locations for Area 1/2/3/4, and Figures 2.10-2 through 2.10-6 show the sampling locations for Area 18.

ISR work conducted in Area 18 is described in Section 2.20.3, 2.20.13, 2.20.14, 2.20.15, and 2.20.16.

2.11 AREA 25—ACID PRODUCTION AREA SOIL QUALITY

2.11.1 History of Activities

Area 25 encompasses the facilities used for production of sulfuric and nitric acids and for storage of the production process materials (e.g., sulfur). Changes occurred in the layout of the acid

production area over the period of operations (1900s to 1970s). Maps showing two sets of composite historical features for the area developed from historical DuPont plant maps and aerial photographs were included in the Sampling and Analysis Plan (Hart Crowser 1992a).

Elevated lead concentrations were observed in pre-RI samples collected from Area 25.

Surficial grading of much of the northern portion of Area 25 was conducted to prepare staging and stockpile laydown areas in support of Area 5 ISR activities. In addition, surficial grading of a stockpile laydown area was conducted in the southern portion of Area 25 during ISR at the Trivelene melt house. Limits of graded areas and the limit of the Trivelene melt house excavation are shown in Figure 2.11-1. All sampling depths listed in Tables B.8-1 and B.8-2 in Appendix B and in Figure 2.11-1 are referenced to existing grade.

2.11.2 Soil Conditions

Steilacoom Gravels were observed to a depth of 10 feet in all Area 25 test pits. A 1- to 2-foot-thick veneer of demolition debris containing bricks, crushed rock, and deteriorated gravels was observed in 7 of the 24 RI test pits excavated in Area 25.

Sampling was also conducted to delineate the extent of surficial demolition debris within and adjacent to Areas 25 and 26. The debris appears to be associated with the demolition of the former buildings in the acid production (Area 25) and acid recovery (Area 26C) areas during plant decommissioning. For the purposes of this sampling, the samples were labeled AP-H to differentiate them from samples collected within the Area 25 and Area 26 production areas. However, the field reconnaissance of the debris indicated that, although the debris was observed outside the current boundaries of Areas 25 and 26, it was not widespread enough to warrant consideration as a separate area. As a result, the lead data from the AP-H sampling locations have been integrated with the data from Areas 25 and 26, and the surficial debris were evaluated as part of Areas 25 and 26. Thus, AP-H is not discussed further in this RI.

A brick wall was observed between depths of 1.5 and 4 feet in the sidewall of 25-TP-505, excavated within the former converter house foundation used in manufacturing sulfuric acid. Lead debris and ceramic pipe were observed in the upper foot of fill at 25-TP-503, excavated within the former scrubber house. A 3.5- by 6-foot, 1.5-foot-thick concrete slab was removed from the wall of this test pit during excavation. The bottom of the slab was weathered and stained a dark yellow color, likely related to the sulfuric acid production process. A similar yellow staining was observed with deteriorated gravels to a depth of 10 feet in this test pit. At 25-TP-514, the end of a clay drain pipe was observed in the north wall of the excavation, and deteriorated gravels were encountered to a depth of 12 feet, with bleached gravels from 12 to 14 feet. Surficial soils in 25-TP-514 were later excavated during ISR. Deteriorated gravels were also observed between depths of 1 and 4 feet in 25-TP-516, below 1 foot of nonweathered soil that appears to be fill.

2.11.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 25 included up to eight total metals, explosives, VOCs, SVOCs, and PAHs. Total metals and explosives were detected in at least one sample from Area 25. Many of these samples were removed during ISR and are no longer

representative of current site conditions. VOCs, SVOCs, and PAHs were not detected in any samples from this area.

Tables B.8-1 and B.8-2 in Appendix B provide an overview of the RI soil quality data for Area 25. Figure 2.11-1 shows the sampling locations.

ISR work conducted in Area 25 is described in Section 2.20.14 and 2.20.16.

2.12 AREA 26—WASTE ACID RECOVERY AREA AND KETTLE SOIL QUALITY

2.12.1 History of Activities

This area includes the facilities used for recovery of spent acids returning from the NG production area. Initially, both sulfuric and nitric acids were recovered in separate facilities. Subsequent (post-1940) processing methods substantially reduced the number of facilities. The area also includes two geologic kettles (Units 26A and 26B) located south of the recovery facilities (Figure 2.12-1). According to former DuPont employees, the large kettle (Unit 26A) received liquid discharge from the acid recovery area, the plant laundry, and the truck wash and vehicle maintenance facility. Aerial photographs from 1976 show liquid within this kettle. Historical information including aerial photographs indicate that the Unit 26B kettle did not receive liquid wastes.

The former waste acid recovery buildings (Unit 26C) and the small kettle (Unit 26B) were included within Area 25 (Acid Production Area) for the pre-RI site characterization (Hart Crowser 1987). Since Units 26B and 26C include facilities for storage and reprocessing of waste acids, rather than production of acids, these waste acid recovery buildings and both kettles have been included in Area 26 for evaluation in the RI.

During pre-RI sampling in Area 26, elevated lead, cPAH, and DNT concentrations were found.

2.12.2 Soil Conditions

Unit 26A and Unit 26B Kettles

Native soils within the kettles consist of 1 to 10 feet of dark gray, silty, gravelly sand with occasional silt lenses and abundant organic matter (surficial sandy loam), overlying brown, stratified sands and gravels (Steilacoom Gravels), which extend beyond the depth of exploration (100 feet at boring 26-B-503 within Unit 26A). The upper silty sand is thicker at the northern end of the Unit 26A kettle—up to 9 to 10 feet thick at 26-B-5, 26-B-501, and 26-TP-502, compared with 2 to 3 feet thick along the southern edge of the kettle. Some silty to slightly silty zones were encountered in the Steilacoom Gravels, but they appear to be discontinuous between explorations.

The Water Table Aquifer and Aquitard were not encountered to an elevation of approximately 70 feet msl in 26-B-503. This boring was drilled to a total depth of 100 feet specifically to confirm the presence or absence of the aquifer and aquitard at this location. This observation confirms the findings from MW-6 and the current hydrogeologic interpretation that the "Cutoff" (discussed in Section 3.1) is located east of Area 26.

Similar to conditions encountered in the other kettles (Area 7 and Area 16) during drilling of the pre-RI and RI borings, wet soil samples were commonly recovered without the ability to detect water in the auger. These conditions likely indicate wetting fronts infiltrating downward and are consistent with conditions encountered in the other kettles (Sections 2.5 and 2.9).

A zone of saturation was encountered, and a piezometer was installed (screened between depths of 19.5 and 24.5 feet) in the pre-RI boring 26-B-2, which was drilled in April 1987. Water was measured in the piezometer 2 weeks after its installation (Hart Crowser 1987). The piezometer had no measurable water in it during drilling of the RI borings in February and July 1992.

No NG was detected in the three samples collected from 26-TP-508 (within the former NG waste acid storage location) or in the sample collected from pre-RI test pit 25-TP-6, located downslope of the former building. In the Unit 26B kettle, lead debris removal was conducted in the location of the former NG waste acid storage and freezing house (the limit of excavation is shown in Figure 2.12-1).

Unit 26C—Waste Acid Recovery Area

Demolition debris was also encountered in six test pits (26-TP-510 through 26-TP-515) excavated in and around the former waste acid recovery buildings located north of the Unit 26A kettle (Figure 2.12-1). The debris consisted predominantly of bricks and crushed rock, with smaller quantities of wood and ceramic and lead piping. A graded veneer of demolition debris less than 2 feet thick was observed at the surface over much of Unit 26C and east of the road bounding the unit on the east. Beneath the debris, the soils were essentially the same as those observed elsewhere in Area 26—2 to 3 feet of dark gray, silty, gravelly sand overlying Steilacoom Gravels to the depth of exploration. Several additional samples (AP-H samples) were collected within and outside the limit of this debris. The locations of AP-H samples in the vicinity of Area 26 are included in Figure 2.12-1.

Lengths of 4-inch-diameter ceramic pipe were observed at depths of 1 to 2 feet in test pits 26-TP-510 and 26-TP-513. The pipe appeared to be in place (undisturbed) in 26-TP-513, but not in 26-TP-510. In 26-TP-513, the pipe sloped to the south, toward the Unit 26A kettle. A 12-inch-diameter ceramic pipeline, which also appeared to be in place and sloped toward the south, was observed across the full length of 26-TP-511. The ceramic pipe in each of the three test pits was oriented approximately north-south. In addition to the ceramic pipes, an 8-foot length of 3-inch-diameter lead pipe that did not appear to be part of a pipeline was pulled out of the north wall of 26-TP-512, at a depth of 1 foot. There was no indication that this lead pipe was connected to any other piping.

Discharge locations for several pipes were observed along the northern rim of the Unit 26A kettle. At one location a few feet upslope of hand auger 26-HA-502 (Figure 2.12-1), outlets for four pipes were found—a rusted 2-inch-diameter steel pipe and three ceramic pipes (with 4-, 8-, and 12-inch diameters). This location was later excavated to a depth of 10 feet during ISR. From what was visible at the location of the outlets and in the test pits, all pipes appear to originate from the acid recovery area located to the north. In addition, a length of 6-inch pipe was observed lying on the slope below the former Ammonia Neutralizing House, but the pipe did not appear to be in place. The pipe was near the top of an erosion gully that extends into the Unit 26A kettle (test pit 26-TP-502 was excavated within this gully; see Figure 2.12-1).

Stained soils were commonly observed at the surface and at depth in the Unit 26C test pits. Crumbly, deteriorated gravels and rock fragments (fill), commonly bleached or stained, were observed on the surface of much of the area including immediately downslope of the pipe outfalls (26-HA-502). Beneath the surface, rusty yellow soil staining was observed in the three test pits where ceramic piping was observed (26-TP-510, 26-TP-511, and 26-TP-513). In 26-TP-510, the staining was minor and did not appear to be associated with the piping. In 26-TP-511, the soil staining started at a coupling between sections of the 12-inch ceramic pipe and spread laterally with depth, extending to the depth of exploration (11 feet). A small area of stained soil was observed beneath a coupling in the 4-inch ceramic pipe at a depth of 3 feet along the south wall of test pit 26-TP-513. Similar staining was observed between depths of 4 to 10 feet along the west wall of the test pit, but it was not continuous with the staining next to the pipe and did not appear to be related to the 4-inch ceramic pipe. No other piping was observed in this test pit. Soil at test pit locations 26-TP-11 through 26-TP-13 and 26-TP-15 was later excavated to a depth of 3 to 4 feet during ISR.

Deteriorated, stained gravels were also observed in the upper 3 feet of 26-TP-514 (no pipes were observed). The upper 2 feet of silty sand in this test pit was interbedded with a colored, ash-like material. At a depth of 7 feet, cemented gravels were found; they appeared to be native—not concrete or other man-made material. Several unsuccessful attempts to penetrate the material were made, including enlarging the test pit. The material was too dense to be sampled, even using the backhoe. This condition was not observed in any other exploration on site.

2.12.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 26 included up to nine metals, TPH (non-Bunker C), explosives, SVOCs, and PAHs. All of these analytes were detected in at least one sample from Area 26. Many of these samples were removed during 1999, 2000, and 2001 ISRs and are no longer representative of current site conditions. Two phthalate compounds, detected in a single sample, were the only SVOCs detected in any of the samples. Analyses were also performed for Bunker C fuel, diesel, gasoline, kensol, kerosene, and Stoddard solvent in two selected soil samples. These compounds were not detected in either sample.

Tables B.9-1 through B.9-5 in Appendix B present an overview of the RI soil sampling results from Area 26. Figure 2.12-1 shows the sampling locations.

ISR work conducted in Area 26 is described in Sections 2.20.15 and 2.20.16.

2.13 AREA 31—BURNING GROUND SOIL QUALITY

2.13.1 History of Activities

Materials from the Site were burned for many years at this location. Within a fenced area of the burning ground, 6 to 24 inches of highly variable material overlying sandy gravel soils were uncovered during the pre-RI field work. This material consisted of black, ash-rich, tar-like residue with rusting iron, glass, ceramic fragments, and varying amounts of lead debris. A mound of burned residual materials was present in the center of the burning ground. Visible lead debris and lead-coated steel grating and bricks were also observed within a 10- by 100-foot area. Solid debris, including rusting metals and ceramics, was observed adjacent to and north of the

burning ground during pre-RI investigations. Several partially buried drums were located in a depression (ravine) south of the burning ground. Other buried materials included charcoal, ash, bricks, glass, auto body parts, and pipes.

Fifty-four soil samples were collected from 21 test pits, 1 boring, and 2 surface locations during the pre-RI work. The pre-RI soil samples had elevated concentrations of DNT, TNT, lead, and cPAHs.

2.13.2 Soil Conditions

Debris and/or fill material was encountered in RI test pits 31-TP-501, 31-TP-502 (1 to 3 feet of soil was later excavated from this location during ISR) and soil boring 31-B-501 (3 feet of soil was later excavated from this location during ISR), all within the burning ground, and in 31-TPH-508, which was excavated during ISR of the Area 31 ravine. Debris consisted of brick fragments, lead debris, nails, scrap metal, and glass. Depth to water in the five RI borings ranged from 17 to 22 feet below ground surface.

2.13.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 31 included up to 10 total metals: TPH, explosives, SVOCs, PAHs, and PCBs. All of these analytes, except for PCBs, were detected in at least one sample from Area 31. TPH was detected once at a concentration near the detection limit and the result was therefore qualified. In addition, the only SVOC detected was bis(2-ethylhexyl)phthalate, in three samples at concentrations near the detection limit; these results were also qualified. PCBs were not detected in any samples from this area.

Tables B.10-1 through B.10-6 in Appendix B detail the soil sampling explorations and depths of sample collection and summarize the soil quality data in Area 31. Figure 2.13-1 shows the sampling locations.

ISR efforts in 1999, 2000, and 2001 removed the majority of the elevated concentrations in Area 31. ISR work for this area is described in Sections 2.20.8, 2.20.13, 2.20.14, and 2.20.15.

2.14 AREA 38—CARTON PRODUCTION AREA AND DRYWELL SOIL QUALITY

2.14.1 History of Activities

Area 38 encompasses the buildings used for production and labeling of the cartons used to package and ship the products from the Site. Packaging materials were originally wooden boxes, which over time were replaced by paraffin (wax)-coated cardboard cartons. Both cardboard printing and paraffin coating activities occurred in this area. Water and/or solvents used to clean printing equipment in the box factory reportedly drained through a wooden trough from the building into a drywell, which is an approximately 3-foot-square, 7-foot-deep, wood-lined location approximately 15 feet south of the box factory.

Five surface samples were collected in Area 38 as part of the pre-RI sampling program. Elevated lead concentrations were observed in the pre-RI samples from beneath the trough and the drywell bottom.

2.14.2 Soil Conditions

Subsurface explorations were conducted within the drywell (38-B-501) and beneath the trough that leads from the box factory to the drywell (38-TP-501).

Soil boring 38-B-501 was advanced to a depth of 16 feet below the drywell bottom (23 feet below grade). A gray, fine-grained non-native fill material with a noticeable sulfur smell was encountered in the first 2 to 3 feet below the drywell bottom. Steilacoom Gravels with minor silt were encountered below this material to the depth of exploration.

Fill containing wood debris, copper wire, and ACM was encountered to a depth of 6 feet below grade in 38-TP-501. The ACM observed in the test pit was removed by TLH Abatement Inc. and disposed of at Thun Field Landfill in Puyallup, Washington. The debris fill was localized to a 3- to 4-foot-wide area immediately beneath the surficial wooden trough. Undisturbed Steilacoom Gravels were observed on either side of the fill and beneath it (below 6 feet).

2.14.3 Constituents in Soil

Laboratory analyses performed on soil samples from Area 38 included up to 14 total metals, TPH, diesel, gasoline, explosives, VOCs, SVOCs, PAHs, and pesticides. Total metals, TPH, SVOCs, and PAHs were detected in at least one sample from Area 38. Results from the paraffin investigation (Hart Crowser 1996) indicated that the TPH in Area 38 was diesel-range and oil-range TPH, not paraffin. Many of these samples were removed during 1999, 2000, and 2001 ISRs and are no longer representative of current site conditions. The only SVOCs detected were two phthalate compounds, each detected in single samples. The detected concentrations were near the detection limits; therefore, these results were qualified. Explosives, VOCs, diesel, gasoline, and pesticides were not detected in any samples from Area 38.

The RI soil quality data and associated sampling depths in Area 38 are summarized in Tables B.11-1 through B.11-7 in Appendix B. Sampling locations are shown in Figure 2.14-1.

ISR work conducted in Area 38 is described in Sections 2.20.11 and 2.20.16.

2.15 AREAS OF POTENTIAL CONCERN SOIL QUALITY

In response to Ecology comments, the Sampling and Analysis Plan for the APs provided in the Management Plan (Hart Crowser 1992a) was expanded to include test pits at one or more locations within each AP, as discussed in Hart Crowser (1992b).

Laboratory analyses were performed on soil samples from the seven APs (AP-A through AP-G). Results from these analyses are discussed separately in the following subsections.

2.15.1 AP-A Powder Test Ground

History of Activities

Area AP-A was defined to address a former "powder test ground" (explosives detonation area) that operated during the 1950s and 1960s. Specific features associated with the area no longer exist. The test ground, as shown on a 1955 historical map, measures approximately 125 by 75 feet. The test ground was located near the western plant boundary, west of the main powerhouse

within the CDB. A review of aerial photographs suggested two possible areas that corresponded to the 1955 historical map location: one immediately west of the former nitrostarch nitrating building (Area AP-C) and the other farther west within the CDB. The latter correlates with distances from nearby structures, as shown on the historical map, but is not observed as a distinct clearing in aerial photographs (as is the former location).

Before locations were staked for the RI sampling, an extensive field reconnaissance of the area was conducted. No indication of features potentially associated with historical testing was evident other than a location south of the area, which appeared to be unnaturally flat. Explorations were located to provide coverage of both potential areas and the flat area to the south. The exploration locations are shown in Figure 2.15-1.

Soil Conditions

During the RI, one test pit was completed and two surface samples were collected in AP-A. Undisturbed Steilacoom Gravels were encountered to a depth of 5 feet in APA-TP-501 (Figure 2.16-3).

Constituents in Soil

Laboratory analyses performed on soil samples from Area AP-A included total metals and explosives. Both analytes were detected in at least one sample from Area AP-A. Analytical data for soil samples collected from AP-A during the RI are presented in Tables B.14-2, and B.12-1 through B.12-7 in Appendix B. Sampling locations are shown in Figure 2.15-1.

2.15.2 AP-B Smokeless Powder Dump

History of Activities

Smokeless powder, which consisted of nitrate, cellulose, NG, and plasticizers, was stockpiled in three structures in this area between World War I and 1928. Two test pits were sampled in this area during the pre-RI sampling (Site 22 in Hart Crowser 1987). NG was not detected in the sample from either pre-RI test pit.

Soil Conditions

During the RI, two test pits and two surface samples were completed in AP-B. Undisturbed Steilacoom Gravels were encountered in both APB-TP-501 (later excavated to a depth of 5 feet during ISR) and APB-TP-502. Bricks were observed at the surface approximately 20 feet west of the APB-TP-502 location, and they were the reason the exploration was located there. Short stakes and string were also observed around the bricks, indicating possible archaeological excavations in conjunction with a reported historic oxen trail running through this area to Puget Sound. Prior to excavation at this location, field personnel conferred with archaeologist Dr. Richard Daugherty of Western Heritage, who gave permission for excavation to proceed. No cultural resources were observed in the immediate vicinity either in the excavation or on the surrounding surface. The exploration locations are shown in Figure 2.15-2.

Constituents in Soil

Laboratory analyses performed on soil samples from Area AP-B included explosives and nitrate. Nitrate was detected in at least one sample from Area AP-B. Explosives were not detected in any samples from this area. The soil quality data are summarized in Tables B.12-1 through B.12-7 in Appendix B.

2.15.3 AP-C Smokeless Powder Nitrating/Grinding House

History of Activities

Between 1916 and 1928, nitration of nitrocellulose and nitrostarch was conducted in this building. During the same time period, smokeless powder pellets were ground into fine powder for use as an admixture in the dynamite process.

Soil Conditions

During the RI, two test pits and one observational test pit were completed, and 14 surface samples were collected in AP-C. Undisturbed Steilacoom Gravels were observed in APC-TP-501, and later excavated during ISR to a depth of 5 feet. At the time of sampling, small pieces of lead debris were observed on the Nitrating/Grinding House foundation and on the ground adjacent to the foundation. Review of the architectural plans and sections for this building indicated possible lead lining in a portion of the former building. As a result, additional surfaces samples (APC-SS-505 through APC-SS-514; surficial soil at locations APC-SS-505 through APC-SS-509 was later excavated during ISR) were collected and analyzed for lead. Test pit APC-TP-502 was excavated at the mixed acid storage area to evaluate metals concentrations at depth, and later it was excavated to a depth of 1 to 3 feet during ISR. Some bleached gravels were observed between depths of 1 and 7 feet in this test pit. The exploration locations are shown in Figure 2.15-1.

Historical architectural plans indicated that a “sump well” might be present adjacent to the southwest corner of the nitrator foundation. Observational test pit APC-TP-503, covering a surface area of approximately 30 by 18 feet, was excavated to a depth of about 4 feet in this area to look for subsurface evidence of this feature (Figure 2.15-1). No evidence of a sump well was observed in the large excavation.

Demolition debris (mostly wood) was observed at the surface in the location of the northern room of the Nitrating/Grinding House, which was pile-supported.

Constituents in Soil

Laboratory analyses performed on soil samples from Area AP-C included total metals, explosives, and nitrate. All three parameters were detected in at least one sample from Area AP-C. Many of these samples were removed during 1999, 2000, and 2001 ISRs and are no longer representative of current site conditions. The soil quality data for the AP-C area are summarized in Tables B.12-1 through B.12-7 in Appendix B. Sampling locations are shown in Figure 2.15-1.

2.15.4 AP-D Asphalt Paint Building

History of Activities

This building was used prior to the 1940s for heating asphalt for coating structures such as the NG gutters in the NG production area. Although called an asphalt paint "kettle" on historical maps, the term kettle at this building refers to the melting pot and facility function, rather than to a glacial kettle (geologic depression), as the term is used elsewhere in this report.

Soil Conditions

During the RI, one test pit was completed in AP-D. AP-D occurs within an area covered with a veneer (0 to 2 feet thick) of disturbed soils, crushed rock, and demolition debris (e.g., bricks and mortar). There was no surficial evidence of the former Asphalt Paint Building in the vicinity. The extent of this demolition debris was discussed in Sections 2.11 and 2.12.

To look for subsurface evidence of the building foundation, APD-TP-501 was excavated along an approximately 20-foot length in the location of the former building, as determined from historical maps (Figure 2.12-1 and Tables B.9-1 through B.9-5 in Appendix B). Fill with demolition debris similar to the surface materials was observed to a depth of 3 feet in this excavation. Occasional small pieces of hard tar-like material and lead debris were observed in the upper 6 inches of fill. Native Steilacoom Gravels were observed below a depth of 3 feet. Due to the significant surface disturbance, the proposed surface samples APD-SS-501 and APD-SS-502 were not collected.

Constituents in Soil

Laboratory analyses performed on soil samples from Area AP-D included total metals, TPH, explosives, SVOCs, and PAHs. Total metals, TPH, and PAHs were detected in at least one sample from Area AP-D. Explosives and SVOCs were not detected in any samples from this area. Analytical data for soil samples collected from AP-D during the RI are presented in Appendix B, Tables B.12-1 through B.12-7.

2.15.5 AP-E Main Transformer House

History of Activities

Although two powerhouses were located at the plant, the Puget Sound Power and Light Company was its main source of electrical power. The transformer house served as the main power and switching yard throughout the period of manufacturing operations.

Soil Conditions

During the RI, 2 test pits and 13 surface samples were completed in AP-E. Bricks and demolition debris are scattered around the surface of the former Main Transformer House. In APE-TP-501, located immediately adjacent to the building foundation, 6 inches of the brick debris was underlain by a 2- to 3-inch layer of black silty soil, which was underlain by

Steilacoom Gravels to a depth of 5 feet. In APE-TP-502, excavated along the eastern edge of the foundation, native soils were observed beneath approximately 1.5 feet of sandy gravel fill. Some debris from the foundation was also observed down the slope in the vicinity of surface soil sample location APE-SS-501.

Constituents in Soil

Laboratory analyses performed on soil samples from Area AP-E included total metals, TPH, and PCBs. Total metals and TPH were detected in at least one sample from Area AP-E. Many of these samples were removed during 1999, 2000, and 2001 ISR and are no longer representative of current site conditions. PCBs were not detected in any samples from this area. Analytical data for soil samples collected from AP-E during the RI are presented in Tables B.12-1 through B.12-7 in Appendix B. Sampling locations are shown in Figure 2.15-3.

2.15.6 AP-F Nitrocotton Area

History of Activities

Drying and screening of nitrocotton fibers as additives to the dynamite process were conducted in this area from the early years of production until their use was discontinued in 1960. The facilities were burned as part of the plant decommissioning.

Soil Conditions

During the RI, 1 test pit, 1 hand-augered boring, and 23 surface samples were completed in AP-F. Metal and wood debris was observed at the surface within the berms surrounding the Nitrocotton Dry House (APF-TP-501) and the Dry Cotton Store House (APF-SS-502). Debris was not observed below grade in APF-TP-501, where Steilacoom Gravels were observed to a depth of 5 feet.

Constituents in Soil

Laboratory analyses that were performed on soil samples from Area AP-F included metals, explosives, and nitrate. Metals and nitrate were detected in at least one sample from Area AP-F. Many of these samples were removed during 1999, 2000, and 2001 ISR and are no longer representative of current site conditions. Explosives were not detected in any samples from this area. Analytical data for soil samples collected from the AP-F during the RI are presented in Tables B.12-1 through B.12-7 in Appendix B. Sampling locations are shown in Figure 2.15-4. Based on site characterization results, detectable lead, barium, and chromium remain in this area.

2.15.7 AP-G Decontamination Areas

History of Activities

Plant equipment was cleaned of incidental residual NG and residual explosives at a decontamination facility from at least the late 1950s through the early 1970s. Decontamination

consisted of hot water washes, application of NG remover (alcohol, acetone, and sodium sulfide), and neutralization with either glycerin or diethylene glycol.

Two areas near the maintenance shop facilities were identified as locations of possible equipment cleaning activities. Field efforts to identify the first (referred to as the southern unit) located demolition debris (bricks and concrete foundation) at the location.

The second (referred to as the northern unit) appeared on historical maps from the 1950s labeled as the "decontamination bath." Scaled distances from the map suggested a location in this area slightly northwest of an existing large rectangular concrete slab. Review of the 1961 aerial photograph identified a small, square structure located where a small, square concrete slab now exists. The aerial photograph indicates equipment was originally stored on a graded area to the north and was subsequently stored on the large rectangular concrete slab. This decontamination facility remained on the Site up to the time of plant decommissioning. Remaining features include the laydown slab and the smaller, square concrete slab that served as the foundation for the decontamination structure.

The southern unit was identified as Site 23 in the pre-RI, although both areas subsequently were tested. NG, TNT, and DNT were not detected in samples from either pre-RI test pit. Based on a review of prior sampling efforts and information from additional aerial photograph review, additional tests during the RI appeared to be warranted and the two localities were redesignated as AP-G.

Sampling locations focused on proximity to structural features and areas susceptible to runoff collection from cleaning operations. In addition, a test pit (APG-TP-502, discussed below, and later removed during ISR work) was excavated at the more northwestern location identified through historical mapping to ascertain whether activities could have occurred at this location rather than at the more obvious confirmed features.

Soil Conditions

During the RI, three test pits and one observational test pit were completed, and three surface samples were collected in AP-G. In the northern unit, a variety of equipment and scrap metal was being stored on the large rectangular concrete slab next to APG-SS-501 and APG-SS-502. Some scrap metal and piping were also stored on the smaller, square concrete slab adjacent to the southeastern corner of the large slab.

Steel rebar and electrical wiring were observed in the upper 2 feet of APG-TP-504, excavated between the large and small slabs (Figure 2.15-3). A 1-inch-diameter steel water supply pipe was encountered 1.5 feet below grade in APG-TP-501, excavated within a shallow swale leading away from the area. Other than the piping and wiring, only Steilacoom Gravels were observed in these two test pits.

APG-TP-502 (an observational test pit, where no samples were collected) was excavated in a very small depression (apparently natural) at the location northwest of the rectangular concrete slab. This excavation was conducted to look for any evidence of the former decontamination bath structure, and thereby confirm the more recent interpretation of the historical aerial photographs, which indicated that the bath was located at the small northern slab. There were no surficial indications of a structure or other man-made disturbance anywhere in the vicinity of

APG-TP-502. Similarly, there were no indications of subsurface disturbance noted in the excavation.

APG-TP-503 was excavated next to the former building (concrete foundation and bricks remaining) in the southern unit (Figure 2.16-3). Native Steilacoom Gravels were encountered to the 5-foot depth of exploration in this excavation. APG-SS-503 was completed in a shallow natural depression downslope of the former building.

Constituents in Soil

Soil samples from Area AP-G were analyzed for explosives and metals. Explosive compounds were not detected in any samples from this area. Analytical data for soil samples collected from AP-G during the RI are assigned to the Site Reference Area and presented in Tables B.14-1 and B.14-2 in Appendix B. All AP-G sampling locations are shown in Figure 2.16-3.

ISR in the AP areas was conducted in areas AP-B and AP-C as described in Section 2.20.16.

2.16 SITE REFERENCE AREA SOIL QUALITY

The Site Reference Area includes the portion of the Site that lies within the CDB but outside the production/disposal areas that received more detailed environmental characterization. Two exceptions are a reference grid of surface samples in Areas 18 and 31 (Area 18-Reference and Area 31-Reference), which were analyzed for arsenic and are included in this section to allow a better understanding of the distribution and sources of arsenic on a Sitewide basis (Figures 2.16-1 and 2.16-2 and Tables B.13-1 and B.13-2). Historical research has not identified any activities or manufacturing processes that would impact the soil quality in these outlying areas. Historical activities in the Site Reference Area were primarily restricted to transportation corridors.

Due to the elevated lead concentrations in many areas of the Site, soils beyond the designated production facilities and disposal areas were evaluated for lead. Similarly, elevated arsenic concentrations were found in peripheral areas, apparently unrelated to specific production or disposal areas. Therefore, arsenic was evaluated using a systematic Sitewide investigation.

Surface (0- to 6-inch depth) samples were collected from 70 locations in the Site Reference Area and analyzed for lead. Later, these same locations, as well as an additional 23 reference locations in Area 18, were resampled for arsenic. Because elevated arsenic concentrations were frequently encountered in the soil samples and the arsenic distribution was not well defined after the initial round of sampling, more comprehensive arsenic sampling was subsequently conducted in the Site Reference Area. An additional 485 surface samples and 48 subsurface samples (to a 2-foot depth) were collected to better define the Sitewide distribution of arsenic.

2.16.1 Lead

The Site Reference Area was systematically sampled on a staggered grid of 500-foot centers (Figure 2.16-3). Surface samples were analyzed for lead (Lead Reference [LR] Area) using both XRF and atomic absorption (AA) techniques. Subsequently, the five highest concentrations (in samples LR-19, LR-38, LR-62, LR-68, and LR-102) were crossed with additional samples offset by 125 feet to assess the spatial extent of lead in these locations.

Following initial review of the data, more detailed assessments were completed in the area of samples LR-68 and LR-62.

XRF Versus AA Lead

Surface soil samples were screened in the field with a portable XRF probe calibrated to Site soils. Twenty-five samples were selected at random and submitted to a laboratory for confirmation analyses by AA. The five highest XRF readings were also submitted for confirmation analysis. Lead determinations by XRF and AA are well correlated ($r^2 = 0.90$) and support the use of XRF as a screening tool.

Two samples (LR-91 and LR-104) were classified as outliers and omitted from the correlation because XRF and AA results differed for these samples by an order of magnitude. The discrepancy likely resulted from inherent differences in the analytical techniques: XRF measures a surface area of the soil, whereas AA is a volumetric extraction. In addition, XRF is probably more susceptible to high bias imparted by random sampling of small pieces of particulate lead. In both of the outlier samples, the laboratory results were substantially lower than the field screening results, so omission of these samples is conservative in terms of using the regression to predict lead concentrations based on XRF screening.

XRF and AA data were combined to evaluate data during Site characterization. AA lead determinations were preferentially used where laboratory confirmation data exist; otherwise, XRF values were used. The use of XRF data is likely conservative because the regression model suggests that screening values tended to overestimate the analytical lead concentrations. For example, an XRF value of approximately 400 mg/kg equates to an analytical lead concentration of 250 mg/kg (as predicted, on average, by the regression model). Although screening data proved useful during Site characterization, they were not retained in the database developed for this RI (Pioneer 2002).

Spatial Distribution of Lead

Most of the elevated lead concentrations occur along the perimeters of designated production areas in the north-central part of the Site and are likely derived from these adjacent facilities (Figure 2.16-3).

2.16.2 Arsenic

Soil arsenic concentrations above site-specific background levels (i.e., 33 mg/kg) were observed in unrelated areas across the Site. Many of the results showed no apparent relationship to production facilities, disposal sites, or specific point sources. In order to evaluate the potential Sitewide distribution of arsenic, the Site Reference Area and Area 18-Reference were sampled on 500-foot centers for arsenic. Table B.14-1 and B.13-1 in Appendix B present analytical results for arsenic in the Site Reference Area and Area 18-Reference, respectively. Initial results from the 500-foot grid indicated that moderately elevated arsenic concentrations range across the Site.

Subsequently, a comprehensive Sitewide sampling program targeting the source and distribution of arsenic was implemented. This program included the following elements:

- **Grid Sampling of the Site Reference Area on 250-Foot Centers.** The Site Reference Area was sampled using a higher resolution grid (303 samples, including the original 500-foot grid samples). The grid was also extended into the Area 18-Reference (124 samples) (Figure 2.16-1).
- **Fine-Scale Grid Sampling in Two Areas.** A second phase of fine-scale grid sampling (10- to 125-foot centers) was conducted in two areas where relatively high arsenic concentrations were observed based on the 250-foot grid. One area of detail is located just south of Area 26, and the other area is located in the central part of the Area 18-Reference (120 samples).
- **Depth Sampling at Selected Locations.** At grid locations with elevated arsenic, hand-augered samples were collected from subsurface depths to define the vertical extent of arsenic in Site Reference Area soils (52 samples).
- **Arsenic Speciation Analyses.** Soil samples with known elevated arsenic concentrations from various areas were submitted for speciation analyses in an attempt to identify potential arsenic source(s) (6 samples).
- **Sampling of Utility Corridors and Motor Houses.** To evaluate the hypothesized use of arsenical herbicides for weed control, two cleared utility corridors on the bluff were sampled (16 samples). In addition, surface soils near several motor houses in Area 18 were sampled (8 samples).
- **Sampling of Railroad Grades.** Both narrow-gauge and standard-gauge railroad grades were extensively sampled for arsenic, and selected locations were sampled for lead. These results are presented in a separate discussion (see Sections 2.17 and 2.18). The data indicate that standard-gauge railroad samples and samples collected 50 or more feet from the narrow-gauge tracks were not statistically different from the Site Reference Area samples; therefore, these samples were included in the Site Reference Area (84 samples).

Spatial Distribution of Arsenic

Grid sampling for arsenic on 250-foot centers did not reveal clear or consistent distribution patterns. The following general observations can be made, although exceptions occur:

- Elevated arsenic concentrations are found in some stretches along the property boundary, particularly near the main gate on the southeast boundary, and along the bluffs northwest of Area 18.
- Elevated arsenic concentrations are found near the periphery of certain areas with known elevated arsenic concentrations.
- Elevated arsenic concentrations appear to be locally related to edge effects from railroad corridors, e.g., along the mainline track, which follows the southern bank of Sequalitchew Creek, just inside the eastern boundary of the site (note, however, that samples within 25 feet of the narrow-gauge tracks were not included in the Site Reference Area [see Sections 2.17 and 2.18]).
- Arsenic concentrations are apparently reduced in areas where ISR has disturbed surface soils (e.g., the northern part of Area 18/1/2/3/4).

Fine-scale sampling at 10-foot and 25-foot intervals did not identify any clearer spatial relationships. Alternately high and low concentrations occurred even among closely spaced samples.

Vertical Distribution of Arsenic

Hand-augered borings were completed in 26 locations on the reference grid to delineate the vertical extent of arsenic in soils. Hand-auger locations were selected on the basis of elevated surface concentrations (ranging from 82 to 390 mg/kg) as well as to provide representative coverage across the Site. Subsurface samples were collected at 0.5- to 1-foot and 1- to 2-foot-depth intervals to complement existing surface samples at a 0- to 0.5-foot depth.

Results of the subsurface sampling indicate that elevated arsenic concentrations are largely restricted to the upper 6 inches of soil. Elevated arsenic concentrations were infrequently encountered at depth.

Arsenic Speciation Analyses

Three samples with high total arsenic concentrations from the Site Reference Area and three samples from other Site areas with elevated arsenic concentrations were submitted to the Battelle Laboratory in Sequim, Washington, for arsenic speciation analyses, in an attempt to identify potential arsenic source(s). Arsenic speciation analyses quantified the oxidized (As-V) and reduced (As-III) forms of inorganic arsenic, as well as organic (methylated) arsenic species.

Speciation analyses indicated that arsenic is largely present in its oxidized state (As-V). The common reduced form of arsenic (As-III) accounted for less than 1 percent of the total soil arsenic. In addition, organic (methylated) arsenic accounted for about 4 percent of the total soil arsenic in one sample (LR-104). Both inorganic arsenic acid (As-V) and methylated forms of arsenic acid are used in the formulation of arsenic-based herbicides. Inorganic arsenic-based herbicides are more persistent, whereas organic forms are more readily decomposed. Potential arsenic sources are discussed further in the subsection "Sources of Sitewide Arsenic."

Utility Corridors and Motor Houses

To further evaluate and substantiate the potential historical use of arsenic-based herbicides to control weeds and reduce fire hazard, two utility corridors along the coastal bluffs ("UC-" sample designation, assigned to Site Reference Area, Table B.14-1, Figure 2.16-3) and several motor houses in the Area 18 dynamite production area ("MH-" sample designation, assigned to Area 18, Table B.7-1, Figures 2.10-2 and 2.10-3) were sampled for arsenic.

Results from the utility corridor sampling indicated that moderate concentrations of arsenic (19 to 88 mg/kg) are present in the soil (see Figure 2.16-3). However, soil arsenic concentrations within the corridors, where weed control may have been conducted, are not significantly different from soil concentrations in samples collected outside of the corridors in adjacent vegetated areas. Arsenic concentrations in the utility corridor samples are slightly elevated relative to concentrations in samples from the Site Reference Area. These data do not suggest that utility corridors received above-average herbicide applications. Vegetation in the corridors was possibly controlled by hand.

Results from the motor house sampling indicate that locally high arsenic concentrations (up to 460 mg/kg) are present in the immediately surrounding soil. Seven of eight sample concentrations were elevated. Particularly high arsenic concentrations were detected in samples from motor houses adjacent to the Gelatin Box Packing House No. 2 (140 mg/kg, 18-MH-4, Table B.7-1, Figure 2.10-2), and the Gelatin Cartridge House No. 1 (460 mg/kg, 18-MH-1, Table B.7-1, Figure 2.10-3). Because of their sparking potential, motor houses constituted fire hazards and were, therefore, isolated from the actual dynamite production facilities. These data suggest that motor houses may have received arsenic-based herbicide applications to keep the areas weed free and thereby minimize the potential for fires.

Sources of Sitewide Arsenic

The use of arsenic-based herbicides throughout the Site as an arsenic source is consistent with the available data. According to a former DuPont employee, fire prevention was a primary concern at the Site, particularly in areas where the explosive hazard was high. Weed control through herbicide application was a main component of the facility maintenance program, although the specific compositions of the herbicides used on the Site are not known. Arsenic-based herbicides were commonly used from the early 1900s.

The use of arsenic-based herbicides to reduce fire and explosive hazards is consistent with the following observations and analyses:

- Moderate concentrations of arsenic are widespread throughout the Site and not specifically associated with production activities.
- Arsenic concentrations are spatially heterogeneous and vary over short distances, consistent with the patchy distribution that might result from localized spray applications.
- Elevated arsenic concentrations are surficial in nature and largely confined to the upper 6 inches of soil.
- Speciation analyses indicate that most arsenic is present in an oxidized, inorganic form, such as arsenic acid, which was a common formulation for arsenic-based herbicides.
- Elevated arsenic concentrations are found in Area AP-E (the transformer house), in Area AP-F (the nitrocotton storage), in certain parts of Area 18 (i.e., near the packing houses and motor houses), and in the detail grid south of Area 26 (near the pulp drying houses)—all areas of potential fire and explosive hazard.
- According to a former DuPont employee, herbicides were stored in a warehouse in Area 38; elevated arsenic concentrations were found in Area 38, including in soil adjacent to both of the storage buildings on the east side of the box factory.
- Elevated arsenic concentrations are consistently found along the narrow gauge railroad tracks, which were maintained by DuPont crews, because it was very important to keep explosives transportation corridors free of fire hazards (see Section 2.17).

Arsenic was also a likely by-product of the burning of pyrite during the acid production process. Pyrite originates in sulfide deposits, which can contain arsenic. Arsenic could occur in association with the pyrite burning process or disposal associated with the acid production area. This source may account for elevated arsenic concentrations in Areas 25, 5, and 16. In

particular, arsenic associated with liquid waste conveyed in discharge pipes to the adjacent kettle (Area 5/16) is associated with the subsurface occurrence of arsenic in these areas, which is unique relative to the surficial distribution of arsenic elsewhere on the Site.

Unsubstantiated Sources of Arsenic

Other sources of arsenic have been considered but are not substantiated by constituent testing results and do not appear to be supported by Sitewide arsenic distribution.

Facility decommissioning could have contributed arsenic to soils around buildings if arsenic-based paints were used. Twenty-six samples of building paint were analyzed, and only two samples contained elevated arsenic (810 and 2,800 mg/kg); the remaining samples contained concentrations near or below the detection limit of 50 mg/kg. In addition, elevated arsenic concentrations do not appear to be localized around building foundations. Because only a small percentage of historic building paints contained appreciable arsenic, the paint appears to be an unlikely source.

Three sulfur samples were tested for arsenic impurities, since arsenic may be associated with sulfur ore deposits; however, the results ranged from nondetections to 7 mg/kg. Ten railroad ties were analyzed to determine whether they may have been treated with arsenic-based wood preservative. Low to moderate concentrations of arsenic (maximum of 120 mg/kg) were detected in the tie samples (see Section 2.17), indicating that the ties likely received arsenic during surficial herbicide applications along the rail lines, but were not dipped in arsenic-based preservative. During Site sampling, hand trenching of the railroad grades at 10 locations was conducted to determine whether fill material might have been added to the railroad grade and could potentially be a source of arsenic. The trenching activities indicated slag-like material was not used as grade foundation, but rather the railroad grades were constructed with local Steilacoom Gravels. A former DuPont employee indicated that approximately 1 percent arsenic was commonly added to strengthen lead sheathing and fixtures used in the production facilities. However, arsenic concentrations are not elevated at the Lead Melt House (Area 36), and the presence of arsenic and lead, in general, is not correlated at the Site.

Analytical data for soil samples collected in the Site Reference Area during the RI are presented in Tables B.13-1 through B.13-2 and B.14-1 through B.14-4 in Appendix B (except as noted in the section “Utility Corridors and Motor Houses”). Figures 2.16-1 through 2.16-3 show the sampling locations (except as noted in the section “Utility Corridors and Motor Houses”).

ISR work conducted for lead and arsenic hot spots in 1999, 2000, and 2001 removed the majority of the elevated concentrations. The ISR work is described in Sections 2.20.15 and 2.20.16. Following ISR, mercury remains in the Area 31-Reference Area.

2.17 HISTORICAL RAILROAD GRADES SOIL QUALITY

2.17.1 History of Activities

Two types of railways served the areas within the Site during its operation. An NGRR connected the various production and material storage areas within the facility. A standard gauge railway, operated by the Northern Pacific Railroad, brought raw materials to storage facilities in the plant (e.g., in the acid production and black powder production areas) and

transported finished products from the plant. Many of the rails (both narrow- and standard-gauge) were removed during facility decommissioning, but the railroad grades remain in most locations. The locations of the historical narrow-gauge and standard-gauge grades are shown in Figure 2.17-1.

Surface soils along narrow-gauge and standard-gauge railroad grades within the Site were sampled for arsenic at approximately 500-foot intervals. Based on these results, selected stretches of the grades were sampled at 100-foot intervals to evaluate more detailed spatial variability in arsenic concentration; samples were also collected at 25- and 50-foot distances from the edges of the grades to evaluate arsenic concentrations laterally away from the grades. Based on surficial (0 to 0.5 foot) arsenic concentrations, samples were collected at depth (0.5 to 1 foot and 1 to 2 feet) at 20 locations and analyzed for arsenic. In addition, lead analyses were conducted on the grades on 20 surface soil samples and 6 samples from depth.

Figure 2.17-1 shows all railroad grade sampling locations and arsenic concentrations from surface samples (0 to 0.5 foot). Tables B.15-1 and B.15-2 in Appendix B provide all data for the railroad grade samples.

2.17.2 Soil Conditions

Steilacoom Gravels were encountered at all sampling locations along both the narrow-gauge and standard-gauge grades. The Steilacoom Gravels were used as fill in those portions of the grades that were built up. No non-native fill materials were observed during the RI.

2.17.3 Constituents in Soil

Elevated arsenic concentrations are located on portions of the narrow-gauge and standard-gauge grades. Elevated lead concentrations were also found in four sampling locations. Many of these samples were removed during 1999, 2000, and 2001 ISRs and are no longer representative of current site conditions.

Laboratory analyses that were performed on Site Reference soil samples from the Historical Railroad Grades included lead and arsenic, as discussed above. Up to 12 other total metals, gasoline, diesel, and TPH were also analyzed in five soil samples. Total metals and gasoline were detected in at least one sample from this area. Diesel and TPH were not detected in any samples from this area.

2.17.4 Distribution of Constituents in Soil

Arsenic in Surface Soils

The sampling results indicate that surficial (0 to 0.5 foot) arsenic concentrations are substantially higher on the narrow gauge grades than on the standard-gauge grades.

Interviews with former DuPont employees indicated that the NGRRs historically have been sprayed with herbicides to control weeds as a fire-protection measure. The general consistency in elevated arsenic concentrations along the NGRR grades supports focused application of arsenic-based herbicide as a likely source for the detected arsenic.

The distribution of arsenic along individual stretches of the narrow-gauge lines appears to relate closely to (1) when a line was used, (2) how long a line was used, and (3) whether explosive compounds were handled on or near the line. These generalized patterns are apparent when segmenting the railway corridors and associated arsenic data into functional/temporal areas. Higher surficial arsenic concentrations correspond to the primary production lines and transportation routes (e.g., Area 18 powder lines used for the longest period of time [Gel Mix 1 Line and Dynamite Mix Lines 1 and 2] and the transportation loop connecting the finished product storehouses and the burning ground). These facilities were operated the longest. Other production lines operated for shorter periods of time, such as the Smokeless Powder Line and the Gel Mix 3 Line, show considerably lower arsenic concentrations. Based on these data, the following observations can be made:

- Detected arsenic concentrations likely relate to application of arsenical herbicides to control weeds as a fire protection measure.
- Applications likely occurred between the late 1920s and the early 1960s.
- Concentrations along a specific segment tend to be relatively higher in proximity to manufacturing facilities (with the exception of the primary narrow-gauge shipment line).
- Frequency, concentration, and/or extent of application is greater in explosives manufacturing areas and considerably less for raw materials production areas (e.g., Acid Production Area and the Crystallizer Plant).
- Elevated arsenic concentrations were found at NGRR intersections.
- The standard-gauge railroad apparently did not receive arsenical herbicide treatment due to its infrequency of use, delivery locations, and maintenance by Northern Pacific Railway personnel. Information from a former DuPont employees indicates that the Northern Pacific maintained its rail lines by burning the weeds along the tracks.

Lead in Surface Soils

The NGRR used gas/diesel or electric locomotives at various times during plant operation. The locomotives are possible sources for localized lead concentrations along the railroad grades. Over the duration of railroad use, spot discharges from batteries used in the electric locomotives could have been a potential source for detected lead concentrations. Wear of Babbitt bearings or other metals used for railroad stock could also have been a source for lead on the railroad grades.

ISR work conducted in the NGRR corridor is described in Section 2.20.16.

2.18 SEQUALITCHEW CREEK CANYON SOIL QUALITY

2.18.1 2001 Sequalitchew Creek Characterization

This work, completed between January 10, and 16, 2001, was isolated to within, and immediately adjacent to, the NGRR track bed between the site access road and the Burlington Northern Railroad. This RI reports only the data collected between the site access road and the Parcel 1 boundary. Data collected outside the CDB will be the subject of a future report. The

purpose of this work was to determine if arsenic and lead contamination is present. Sampling was conducted as follows:

- Approximately 2,250 linear feet of NGRR track was divided into 75- by 20-foot sections, and a sampling grid was established in each section.
- A field check was made to determine if site conditions justified adjustments to the sampling grid. The sampling sections and locations were referenced to the existing LR-68 sampling location (e.g., the sample that is 75 feet west of LR-68 was labeled LR-68-75W).
- Ecology was contacted. Two Ecology employees visited the work area to determine if any changes to the grid were necessary. No changes were made.
- A five-point composite soil sample was collected within each 75- by 20-foot section.
- 30 samples were collected and taken to Sound Analytical Services for analysis for lead and arsenic (Method 6010).

The analytical results for arsenic and lead are presented in Tables B.16-1 through B.16-5. Figure 2.18-1 shows the sampling locations.

The following conclusions can be made on the basis of these results:

- **Arsenic.** Arsenic was detected in each sample and the concentration consistently exceeded background concentrations. Two locations had elevated concentrations. These locations were excavated and disposed of during the 2001 ISR (see Section 2.20.16).
- **Lead.** Lead was detected in each sample. One location had a very high concentration (9,200 mg/kg). This location was excavated and disposed of during the 2001 ISR (see Section 2.20.16).

2.18.2 Area LR-68 Characterization

During RI grid sampling in the Site Reference Area, elevated lead concentrations were observed about 20 feet downslope of the rail line running along the east bank of Upper Sequalitchew Creek. Additional lead samples were collected around the original sample (LR-68) and at 100-foot intervals along the downslope bank of the rail line within the CDB. Two additional locations with elevated lead were discovered along the rail line, southeast of LR-68. There is no documented source at this location in historical records. The source of the metals may be associated with railcar maintenance practices or railcar Babbitt bearings/machinery wear.

Twenty-seven surficial soil samples were collected along the rail line. Miscellaneous debris, including metal, ceramic debris, and bricks, was observed in surficial soils in the vicinity of sample LR-68. No debris was observed in samples collected from depths of 1 to 3 feet or from the two other locations with elevated lead concentrations along the rail line southeast of LR-68.

Laboratory analyses performed on Site Reference Area soil samples from LR-68 included total lead and arsenic, as discussed above.

Soil quality data, associated depths, and analytes for Area LR-68 are summarized in Table B.16-1 through B-16-5 in Appendix B. Figure 2.18-1 shows the sampling locations. (Note that one sample each from LR-68 was assigned to Area 31 and Miscellaneous Areas; these samples are therefore shown in Table B.10-1, Figure 2.13-1 and Table B.19-1, Figure 2.19-4, respectively.)

Although, the majority of the elevated concentrations in the area of LR-68 were removed during the 2001 ISR (see Section 2.20.16), elevated concentrations of lead and arsenic remained. Any remaining impacted soils will be evaluated in greater detail in the RA and FS.

ISR work conducted in the Sequalitchew Creek Canyon is described in Section 2.20.16.

2.19 MISCELLANEOUS AREAS SOIL QUALITY

Additional site characterization was conducted at miscellaneous areas across the Site. These data were collected between 1999 and 2001. The purpose of this work was to further characterize the nature and extent of arsenic and lead impacts in these areas. The additional characterization was conducted in three sets of areas:

- Candidate Areas
- North of Creek Areas
- Miscellaneous Historical Areas

Work in the Candidate Areas was a result of public comment on the Site Environmental Impact Statement (EIS) regarding whether parts of the property could be left in their natural condition without requiring remediation. Sampling in historical areas was focused on the Fort Nisqually Cemetery (45PI404) and the south Shell Midden (45PI72). The remaining characterization was conducted in miscellaneous areas north of the creek associated with the Hot Spot ISR (Section 2.20).

Sampling was conducted as follows for the Candidate Areas and Miscellaneous Historical Areas:

- The soil sampling locations for the three areas were determined relative to the Sitewide 150-foot sampling grid, which extended from the northwest corner of the Site. Ecology and the Project Team agreed that subdividing this larger grid into 75-foot sections was adequate for characterizing these areas.
- The samples were labeled according to their position in the grid (e.g., the sample in row 60 and column 32 was labeled R60C32) and remedial unit (RU) location. The location of each sample was surveyed by ESM Consulting Engineers, LLC (ESM).
- North of the Creek Area characterization sampling locations were determined on the basis of the location of hot spots. Characterization samples were collected from each side of a hot spot excavation in order to confirm that the extent of the excavation was adequate.
- A discrete soil sample was collected at each grid point.
- More than 750 samples (including field duplicates) were collected and taken to Sound Analytical Services for analysis for lead and arsenic (Method 6010).

The analytical results for arsenic and lead are presented in Tables B.17-1, B.18-1, and B.19-1. Figures 2.19-1 through 2.19-4 show the sampling locations for the Candidate Areas, North of Creek Areas, and Miscellaneous Historical Areas, respectively.

2.20 INTERIM SOURCE REMOVAL AREAS

The following interim actions were conducted as allowed under the July 1991 Consent Decree signed by Weyerhaeuser, DuPont, and Ecology. This section briefly describes each ISR. More

details for each ISR action are provided in documents listed in Section 5. ISR areas include Areas 5, 6, 8, 10, 18, 19, 20, 24, 25, 30, 31, 35, 36, 39; the hot spot removal areas; sand laydown areas (SLAs); and the Foundation, NGRR, and topsoil laydown areas.

For the interim actions conducted between 1990 and 1993, DuPont Environmental Remediation Services (DERS) conducted source removals (unless otherwise noted). In many cases Olympus Environmental Services provided excavation services for the work. Hart Crowser provided on-site technical assistance and field oversight to DERS and collected appropriate samples during the interim actions. All soil samples were analyzed at Analytical Technologies Inc. (ATI) and/or the Hart Crowser *FAST* Lab (on-site mobile laboratory), unless otherwise noted.

For the interim actions conducted between 1999 and 2001, Active Construction (ACTIVE) conducted source removals. West Shore Corporation, NW, provided oversight, and sample collection was conducted by URS. All soil samples were analyzed at Multichem or Sound Analytical.

All interim actions were detailed in work plans that were reviewed and approved by Ecology prior to the start of work.

2.20.1 Areas 5 and 6 DNT Waste Drum Areas

Area 5 is the hillside above the Area 16 glacial kettle where discarded containers such as 55-gallon drums, demolition debris, and refuse were placed. During pre-RI work, over 1,000 observable drums were noted. Pre-RI soil characterization sampling and drum contents profiling identified the presence of NAX, TPH, PAHs, acids, metals, isopropanol, and glycol. Area 6 is a ravine located to the east of the Area 5/16 glacial kettle.

The purpose of the interim action in Area 5/6 was to remove, clean, and dispose of drums, debris, fill and impacted soil. DERS performed the work between September 1990 and October 1993, in six phases: drum removal, drum decontamination and recycling, waste debris/soil removal, fill removal and screening, impacted soil removal, and verification soil sampling. Asbestos was encountered at various stages of the interim action and was removed by TLH Abatement, Inc. under the direction of Prezant Associates and DERS.

A total of 4,602 drums were removed from Areas 5 and 6. Of the total, 3,601 were apparently empty, 1,279 contained DNT residual, 3 contained TNT residual, and 259 contained non-NAX contents including petroleum products (oils, tars, grease, glycerin, paraffins, salts, ammonium nitrate, glycol, acids, isopropanol, and rain water). A total of 33 apparently empty drums (one contained paraffin and one contained blasting wire) were found in other areas of the Site.

Area 6 contained approximately 1,600 drums; all but seven of the drums were empty. According to the field screening results, four of the unempty drums contained residual ammonia salts and three contained paraffins (nonhazardous waxes).

RI characterization soil samples were collected after the drum removal around the perimeter of the large volume of debris and fill in Area 5. A small volume of debris in Area 6 was removed during ISR. The sampling results for soil/fill material indicated elevated concentrations of metals, DNT, TPH, and cPAHs. Native soils beneath the fill contained no elevated concentrations.

Approximately 25,050 cubic yards of debris and soil were removed from Area 5 and appropriately segregated, stockpiled, and/or disposed of. Final soil verification samples indicated that all NAX met the target interim action levels.

Numerous characterization, verification, and designation samples were collected and analyzed during each phase of work for this interim action. The ISR in Area 5/6 is reported in Hart Crowser (1994c).

Impacted soils remaining on the Area 5 hillside contain elevated concentrations of one or more of four metals (arsenic, lead, cadmium, and mercury), TPH, and PAHs. The majority of these locations were excavated and removed during the 1999, 2000, and 2001 ISR work. Any remaining impacted soils will be evaluated in greater detail in the RA and FS.

Soil quality data, associated depths, and analytes for Area 5 are summarized in Table B.20-1 through B.20-9 in Appendix B. Figure 2.20-1 shows the sampling locations.

2.20.2 Area 8 Bunker C Pipeline and Former ASTs

The purpose of the interim action was to remove the former Bunker C pipeline and associated TPH-impacted soils along the pipeline and in the former aboveground storage tank (AST) area. The pipeline carried Bunker C fuel from the lower powerhouse and wharf area to the upper powerhouse. DERS removed TPH-impacted soils and the pipeline between January 1992 and August 1993. Approximately 29,100 cubic yards of soil and forty 55-gallon drums of residual product/cleaning waters were removed. The entire level portion of the pipeline and associated lead packing in the pipe joints were removed. The sloped section of the pipeline was cleaned and grout filled for abandonment in place.

Prior to source removal, 58 characterization soil samples were collected and analyzed for TPH. Selected samples were analyzed for PAHs, total lead, VOCs, and SVOCs. Following source removal, 48 verification soil samples were collected and analyzed for TPH. Selected samples were analyzed for PAHs. Forty-seven designation samples were collected from Area 8 stockpiles and analyzed for TPH prior to appropriate disposal.

With one exception, the ISR effectively removed all TPH soils where the concentration was above the Bunker C product-specific level of concern to a depth of 15 feet. The one exception is addressed in the FS and the remainder of Area 8 will not be addressed further.

ISR and verification sampling in Area 8 are discussed in Hart Crowser (1994b). An Ecology letter dated October 9, 1996, gave approval to backfill the excavations associated with the pipelines and aboveground Bunker C storage tanks in this area (Ecology 1996c).

Soil quality data, associated depths, and analytes for Area 8 are summarized in Table B.21-1 through B.21-6 in Appendix B. Figure 2.20-2 shows the sampling locations.

2.20.3 Area 18 Sympathetic Detonation

To minimize potential health and safety risks associated with potential explosive residuals within the former manufacturing foundations, an interim action involving sympathetic detonations was conducted where there had been historical use of NG.

Although the facilities in Area 18/1/2/3/4 were burned during site decommissioning, safety concerns were raised by the possibility that residual NG, TNT, or DNT might have permeated the remaining concrete foundations and adjacent soils. To reduce this potential hazard, an ISR was conducted involving a series of sympathetic detonations at selected foundations and along transport lines, primarily in the north and central part of the area—in the nitrators, neutralizers, and mixing houses.

Yenter Environmental Services and DERS conducted sympathetic detonations in 1992. The first phase of detonations was conducted at 15 foundations. The second phase was conducted in two additional foundations, various drainage ditches, and miscellaneous wash-down areas. Sympathetic detonations were repeated three times at each foundation's location following foundation removal.

At locations where residual explosives were suspected, detonations were set off. If residual explosive material was present in sufficient quantity, a secondary (sympathetic) explosion would result. As part of the ISR, foundation debris containing lead was sorted, removed, and appropriately disposed of; associated cover and berm soils were stockpiled. Where possible, lead debris was segregated and recycled. Following the sympathetic detonations, test pits were excavated at the foundations to characterize postdetonation soil quality, because many of the soils and fill materials evaluated during the pre-RI sampling were subsequently removed and/or stockpiled during these activities.

As part of the sympathetic detonation program, the concrete splash box next to the NG waste acid storage location in Unit 26B was detonated. The charge produced a second detonation, indicating that residual NG may have been present in the box. Secondary sympathetic detonations were not noted at other locations.

Following this work the soil berms, concrete walls, and timbers were demolished and removed. Soil excavated in association with the removal was stockpiled for designation and appropriate disposal. Following excavation of foundations, characterization soil samples were collected and incorporated into the RI database. Soil samples were analyzed for NAX, NG, and total metals.

Most of the elevated arsenic and lead concentrations remained after the initial ISR in Area 18 were remediated during the 1999, 2000, and 2001 ISRs. Any remaining impacted soils will be evaluated in greater detail in the RA and FS.

Sympathetic detonation activities and verification sampling in Areas 18 are discussed in Hart Crowser (1993b).

2.20.4 Area 19 Maintenance Areas

The purpose of the interim action was to remove paint and petroleum-stained soils at the former Paint Shop (19A) and Oil House (19B). DERS removed TPH- and lead-impacted soils and inorganic solid debris (ISD) between March and September 1992. Approximately 20 cubic yards of soil and 15 cubic yards of concrete and metal debris were removed from these areas.

For Area 19A, seven characterization, verification, and designation soil samples were collected and analyzed for PAH, TPH, VOCs, or total metals. For Area 19B 27 characterization, verification, and designation soil samples were collected and analyzed for PAH, TPH, VOCs, lead, or total metals.

ISR efforts effectively removed the majority of all constituents of concern to a depth of 15 feet. Any remaining impacted soils will be evaluated in detail in the RA and FS.

ISR and verification sampling in Areas 19A and 19B are discussed in Hart Crowser (1993c), in Area 19C in Hart Crowser (1993h).

Soil quality data, associated depths, and analytes for Area 19 are summarized in Table B.22-1 and B.22-2 in Appendix B. Figure 2.20-3 shows the sampling locations.

2.20.5 Area 20 Underground Storage Tanks

The ISR effectively removed all constituents on concern to a depth of 15 feet. Therefore, Area 20 will not be addressed further.

Removal, verification sampling, and closure of the Area 20 underground storage tanks (USTs) are documented in Hart Crowser (1991d). Additional removal of soil associated with an AST in Area 20B is documented in Hart Crowser (1993a). Ecology issued a letter specifying No Further Action (NFA) for Areas 20A and 20B (Ecology 1993a).

2.20.6 Area 24A Upper Power House

The Upper Power House was served by the Area 8 Bunker C Pipeline and used Bunker C fuel to power the entire former facility. The ISR in this area was conducted in several phases between 1989 and 1992. The purpose of the interim action was to demolish the Upper Power House including the powerhouse stack. Prior to demolition activities, characterization and lead abatement were conducted. Procedures were established for removal or containment of any remaining lead-paint-impacted material as part of demolition activities.

The 150-foot-high powerhouse stack was initially demolished by a U.S. Army special forces demolition team from Fort Lewis, Washington, on April 29, 1991. Between June 12 and June 18, 1991, CEcon Corporation completed the demolition and disposal of the generated material and associated ACM from the stack. The powerhouse was demolished during subsequent activities. All materials from these demolition activities were appropriately disposed of off Site following waste designation.

Removal of Bunker C TPH material from the Area 8 pipeline, which terminated in the powerhouse, was conducted in association with the Area 8 ISR. Pre-RI characterization in Area 24 identified TPH-impacted material in 4 of 5 hand-auger samples collected from the powerhouse floor sumps. Material from the sumps was removed along with other demolition material.

Soil quality data, associated depths, and analytes for Area 24A are summarized in Table B.21-1 through B.21-3 in Appendix B. Figure 2.20-4 shows sampling locations.

Analysis of the data indicated further action may be required after the ISR and, therefore, this area will be evaluated in greater detail in the RA and FS.

ISR and verification soil sampling in Area 24A are discussed in Hart Crowser (1991e and 1992h).

2.20.7 Area 30 Railroad Debris

The purpose of the interim action was to remove inorganic solid debris (ISD) containing lead in accordance with the Land Disposal Restrictions (LDRs) to decrease potential sources of lead to area soils. DERS removed ISD (approximately 80 cubic yards of soil and 60 cubic yards of timber debris) from Area 30 between March 26 and April 7, 1992. Less than 1 cubic yard of ISD lead was segregated from the excavated materials. Seven soil verification samples were collected and analyzed for lead, TPH, and 13 total metals. Three stockpile designation samples were also collected and analyzed following removal.

Analysis of the data indicated further action may be required after the ISR; therefore, this area will be evaluated in greater detail in the RA and FS.

ISR and verification soil sampling in Area 30 are discussed in Hart Crowser (1993d).

Soil quality data, associated depths, and analytes for Area 30 are summarized in Table B.24-1 in Appendix B. Figure 2.20-5 shows the sampling locations.

2.20.8 Area 31 Ravine Near Burning Ground

DERS removed debris from the ravine area between October 12 and 14, 1992. Approximately 400 cubic yards of soil and 60 cubic yards of debris were removed from the site, including five empty 55-gallon drums and one 55-gallon drum containing tar. Six verification/designation soil samples were collected and analyzed for NAX, arsenic, lead, mercury; one of these was analyzed for PAHs and TPH following removal. Five designation soil samples were collected from area stockpiles and analyzed for NAX, arsenic, lead, mercury, and TPH; three of these were analyzed for pesticides and PCBs, and PAHs.

Analysis of the data from the source removal action indicate that no further action is required in this area.

ISR and verification soil sampling in Area 31 Ravine are discussed in Hart Crowser (1993e).

2.20.9 Area 35 Tar Barrel Area

The ISR effectively removed all constituents of concern to a depth of 15 feet. Therefore, Area 35 will not be addressed further.

2.20.10 Area 36 Lead Melt House

The purpose of the interim action was to remove ISD containing lead in accordance with the LDRs to decrease potential sources of lead to area soils. DERS removed soil and debris at the Lead Melt House from March 25 to March 30, 1993. Approximately 6 cubic yards of soil and 5 cubic yards of debris were removed. Forty-nine soil characterization samples were collected and analyzed for total lead. Concentrations of total lead ranged from not detected to 120,000 mg/kg. Five samples were also analyzed for 13 metals. Four verification/designation soil samples were collected following removal.

Elevated arsenic and lead remained after the initial ISR. These locations were remediated further during the 1999, 2000, and 2001 ISRs. Any remaining impacted soils will be evaluated in greater detail in the RA and FS.

Antimony was detected in one of five samples at a marginally elevated concentration. However, because the antimony detection occurred in a sample with elevated lead and arsenic concentrations, antimony will not be addressed further.

ISR and verification soil sampling in Area 36 are discussed in Hart Crowser (1993f).

Soil quality data, associated depths, and analytes for Area 36 are summarized in Table B.23-1 in Appendix B. Figure 2.20-6 shows the sampling locations.

2.20.11 Area 38 Underground Storage Tank

During the RI soil sampling in Area 38, the fill spout for a UST was observed approximately 20 feet west of the drywell. The contents of the tank were sampled, and the tank was subsequently removed in accordance with Washington State UST regulations. No petroleum product or staining was observed within the tank excavation. Air monitoring (by an HNU photoionization detector [PID] and Draeger tube samples for benzene) indicated no evidence of VOCs. No petroleum compounds were detected in verification soil samples collected within the tank excavation, indicating that the tank did not leak. The UST sampling and removal activities for Area 38 are summarized in a UST Closure Report submitted to Ecology (Hart Crowser 1992f). Ecology issued a letter specifying NFA for the Area 38 UST (Ecology 1993b).

2.20.12 Area 39 Laboratory

The purpose of the interim action was to remove mercury-contaminated soils. DERS removed soils with mercury at the Former Laboratory from March 2 to August 14, 1992. A sump, drainline, UST, and 85 feet of piping were removed. Approximately 1,600 cubic yards of soil were excavated and disposed of off Site. Seventy-six soil characterization samples were collected and analyzed for VOCs, SVOCs, and metals. Five samples were analyzed for mercury speciation by the Battelle Marine Sciences Laboratory. Thirty-four verification soil samples were collected following excavation.

Elevated arsenic, lead, and mercury were detected in one or more samples following ISR in Area 39; therefore, the area will be evaluated in greater detail in the RA and FS.

ISR and verification soil sampling in Area 39 are discussed in Hart Crowser (1993g). Removal, verification sampling, and closure of the UST in Area 39 are documented in Hart Crowser (1992g). On May 6, 1993, Ecology issued a letter specifying NFA for the Area 39 UST (Ecology 1993c).

Soil quality data, associated depths, and analytes for Area 39 are summarized in Table B.26-1 through B.26-6 in Appendix B. Figure 2.20-7 shows the sampling locations.

2.20.13 Lead-Contaminated Debris Removal—Areas 18S, 19C, and 31

The purpose of the interim action was to remove ISD containing lead in accordance with the LDRs to decrease potential sources of lead to area soils. These areas were identified for removal based on visual observations of ISD lead. DERS removed visible ISD lead and soil from Areas 18S (Powderline Area Gelatin Cartridge House No. 3), 19C (Lead Shop), and 31 (Burning Ground) during the first phase of removal in May 1992. The extent of lead debris (not lead concentrations) formed the basis for source removal excavation limits. In July 1993, a second

phase of work removed DNT-impacted soils in Area 31. This was a removal action separate from the one described in Section 2.20.14. Approximately 115 cubic yards of soil and 45 cubic yards of debris were removed from Area 18S. Approximately 55 cubic yards of soil and 25 cubic yards of debris were removed from Area 19C. Approximately 70 cubic yards of ISD lead and associated soil, 40 cubic yards of DNT-impacted soil and 35 cubic yards of debris were removed from Area 31.

Following ISR, 3, 5, and 11 verification soil samples were collected from Areas 18S, 19C, and 31, respectively. Samples from Area 18S were analyzed for total metals, TPH, NAX, and NG. Samples from Area 19C were analyzed for metals. Samples from Area 31 were analyzed for total metals, NAX, and TPH (one sample).

Elevated concentrations of lead remained in soil in Areas 18S, 19C, and 31 after the initial ISR. These areas were remediated further during 1999, 2000, and 2001 ISRs. Any remaining impacted soils will be evaluated in greater detail in the RA and FS. ISR and verification soil sampling for ISD lead in these areas are discussed in Hart Crowser (1993h).

2.20.14 DNT Soil Removal—Areas 10, 18, 25, and 31

The purpose of the interim action was to remove DNT-impacted soil to decrease potential sources of DNT to site groundwater. DERS removed approximately 37,500 cubic yards of DNT-impacted soil from Areas 10, 18, 25, and 31 in February and October 1993.

Following ISR in Area 10, eight verification soil samples (10-VS-1 through 10-VS-8) were collected from the bottom and along the excavation sidewalls. Surficial soil at locations 10-VS-3 and 10-VS-5 was later excavated during subsequent ISR.

In Area 18, residual DNT/TNT-containing soils were excavated in the vicinity of the five foundations. During the excavation at Gelatin Mixing House No. 1, a 4-inch-diameter ceramic/iron pipe filled with DNT/TNT residual was observed. The pipe discharged to the southeast of the mixing house foundation, where crystalline residual was observed. The residual DNT/TNT at the pipe discharge location—approximately 75 by 50 feet and up to 6 inches thick—was carefully excavated as part of the ISR. To address the potential for similar discharge pipes associated with other foundations, a series of continuous trenches was excavated on all four sides of all dynamite and gelatin mixing houses, at distances of 25 to 100 feet from the foundations. No additional discharge lines were observed during the trenching at any of the mix houses.

Following ISR, 6, 173, 16, and 7 verification soil samples were collected from Areas 10, 18, 25, and 31, respectively. All samples were analyzed for NAX. In Area 18, 17 samples were analyzed for total lead, and 2 samples were analyzed for four metals (arsenic cadmium, lead, and mercury). Four samples in Area 25 and all seven samples in Area 31 were analyzed for total lead.

ISR successfully removed soil containing DNT above the ISR excavation target level of 1 mg/kg, and any associated TNT. Analytical results for the verification soil samples indicate that DNT concentrations in the remaining soils were not elevated, with the exception of 5 locations in Areas 18 and 25 locations at a depth greater than 15 feet. One soil sampling location in Area 10 contained an elevated TNT concentration. This location was remediated during 1999, 2000, and 2001 ISRs.

ISR for DNT-impacted soil and verification soil sampling in these areas are discussed in Hart Crowser (1994a).

Elevated concentrations of lead remained in these areas after ISR. These locations were remediated during 1999, 2000, and 2001 ISRs. Any remaining impacted soils will be evaluated in greater detail in the RA and FS.

2.20.15 Lead and Arsenic Hot Spots

Areas with high arsenic and lead concentrations (referred to as "hot spots") were identified during site characterization. Most of the high arsenic locations were along the NGRR track (refer to Sections 2.16 and 2.18), while most of the high lead concentrations were near specific building foundations (refer to Section 2.16).

The two tasks of the hot spot removal program were as follows:

- Remove hot spots in site areas south of Sequalitchew Creek that exceed placement area remediation levels.
- Remove hot spots and other affected soils in the industrial area north of Sequalitchew Creek in order to achieve industrial cleanup levels.

Active Construction (ACTIVE) removed approximately 18,500 cubic yards of soil between September 10, 1999, and July 24, 2000, as part of this interim action. The lead and arsenic hot spot soils were excavated and stockpiled for future treatment and disposal, which was completed in 2001. Soils containing TNT were stockpiled separately and disposed of off Site.

Following hot spot removal, elevated concentrations of lead and arsenic remained. The majority of these locations were remediated during 2001 ISR. Any remaining impacted soils will be evaluated in greater detail in the RA and FS.

Hot spot removals included Areas 10, 31, NGRR, and RR-546. The hot spot excavation in Area 10 was expanded to remove one elevated TNT sample. Since the hot spot removal in these areas, no further action is required.

No hot spot excavations were conducted in open space areas or in areas within or immediately adjacent to known historical sites. These and any other elevated concentration sampling locations within open space or historical areas will be addressed in the RA and FS.

ISR and verification soil sampling in the hot spot areas are discussed in the Hot Spot Interim Action Report (West Shore et al. 2000a).

2.20.16 Foundation, NGRR, Hot Spot, and Top Soil Laydown Area

This interim action resulted in the following soil excavations:

- 2 to 8 feet deep in a 50- by 50-foot area around selected building foundations
- 1.5 to 2.5 feet deep 25 feet on either side of the narrow-gauge track centerline along the selected lengths of NGRR
- 1.5 to 3 feet deep in areas up to 50 by 50 feet around hot spot areas that may require on-Site screening and/or off-Site disposal

  - Arsenic and lead areas (Sequalitchew Creek NGRR, Area 38, and location R71C85)
  - NAX locations in Areas 10 and 18
- 1.5 to 2.5 feet deep in two topsoil laydown areas

ACTIVE removed a total of 158,160 cubic yards of soil between June 4 and September 21, 2001, as part of this interim action. A total of 699 verification samples were collected and analyzed for arsenic, lead, DNT, and TNT. An additional seven characterization samples were collected from remaining hot spot locations and analyzed for arsenic, lead, DNT, and TNT. Based on the

evaluation of sampling data, no elevated concentrations of lead, arsenic, DNT, or TNT remain except for the following:

- Seven locations for arsenic (all in Sequalitchew Creek NGRR)
- Fourteen locations for lead

Further remediation of these locations will be addressed in the FS.

ISR and verification soil sampling in the miscellaneous areas are discussed in the Interim Corrective Action Report (West Shore et al. 2001).

2.20.17 Sand Laydown Areas

The objective of this interim action was to remove surface soil from six areas on the Site so that sand could be stockpiled in these areas and not moved again until final Site remediation. Between 1.5 and 3 feet were removed from each of the six areas in 2000. Verification soil samples were collected within each SLA excavation and analyzed for arsenic and lead.

The results indicated the following:

- In general, postexcavation sample concentrations were near or below background levels for both lead and arsenic. Exceptions were samples with elevated lead concentrations associated with visible debris or foundations.
- No sand was stockpiled in SLA areas where there were visible debris (SLA 1) or foundations (SLA 1, SLA 6).
- With the exception of the debris- and foundation-associated samples, all six SLA areas require no further action.

ISR and verification soil sampling in the miscellaneous areas are discussed in the Sand Laydown Area Interim Action (West Shore et al. 2000b). Figure 2.20-8 shows the sampling locations.

This section presents the findings of the RI groundwater characterization efforts at the Site. Sections 3.1 and 3.2 present specific information on the physical groundwater system and groundwater quality. Appendices A and C present field procedures and tables on groundwater quality, respectively.

3.1 HYDROGEOLOGIC CHARACTERIZATION

3.1.1 Site Geology

The interpretation of the Site geologic and hydrogeologic conditions has been developed from Hart Crowser's work on the Site and from explorations conducted north of the Site by others. The locations of monitoring wells, staff gauges, and geophysical surveys completed by Hart Crowser and used for interpretation of Site hydrogeologic conditions are shown in Figure 3.1-1.

Three major stratigraphic units were encountered during explorations at the Site, the Vashon Drift (which includes the Steilacoom Gravel), the Olympia Beds/Possession Drift/Whidbey Formation/Double Bluff Drift sequence (hereafter referred to as the DBD-OB sequence), and the Salmon Springs Glaciation. Locations of monitoring wells and cross sections are shown in Figure 3.1-1. Generalized subsurface cross sections are shown in Figures 3.1-2 and 3.1-3.

Vashon Drift

The Vashon Drift is composed of the following units, from the surface down (youngest to oldest):

- Steilacoom Gravel
- Vashon Till (observed at only a few locations on the Site)
- Vashon Advance Outwash (comprising Advance Gravel overlying Advance Sand)

Steilacoom Gravel

The Steilacoom Gravel unit of the Vashon Drift was encountered in all of the borings completed at the Site. The Steilacoom Gravel was deposited by high-energy meltwater rivers that flowed generally toward the west from a dammed proglacial lake located in the Puyallup River valley during retreat of the final (Vashon) glaciation (Walters and Kimmel 1968). The Steilacoom Gravel was deposited within the extensive outwash channels carved by the meltwater rivers that covered much of the Tacoma uplands west of the Puyallup River. The rivers discharged their vast quantities of bedload into a pro-glacial lake in the approximate location of Puget Sound, forming the ancestral Sequalitchew and Steilacoom Deltas. The Site is situated on the southern margin of the ancestral Sequalitchew Delta. The ancestral Steilacoom Delta occurs in the Steilacoom/Chambers Creek area several miles to the north.

The thickness of the Steilacoom Gravel unit typically ranges between 20 and 40 feet over much of the eastern portion of the Site. In this portion of the Site, additional gravelly soils (Vashon Advance Outwash Gravels) exist beneath the Steilacoom Gravel, as discussed below. In the western portion of the Site, the Sequalitchew Delta deposits are present. In these deposits, the Steilacoom Gravel has been encountered during explorations to a depth of approximately 220 feet in on-site monitoring well borings (e.g., MW-1). Regional information from a deep

test/production well completed north of the Site indicates that the deltaic Steilacoom Gravel deposits are approximately 330 feet thick, extending to an approximate elevation –120 feet msl.

The Steilacoom Gravel is described as medium dense to very dense, well-graded, light brown and gray, stratified sands and gravels. Generally, the deposits are exceptionally coarse-grained, with localized zones of silty to slightly silty sand. What has been described as Steilacoom Gravel across the Site may also include the Vashon Recessional Gravel unit; similar gravelly materials were deposited during retreat of the Vashon glaciation but prior to the deposition of the Steilacoom Gravel, which is associated specifically with the break of the glacial ice dam to the east. However, it is likely that most of the Recessional Gravel was eroded during deposition of the Steilacoom Gravel, as discussed below.

Vashon Till

Material interpreted to be Vashon Till was encountered in the borings for MW-27 and MW-22 located in the west-central portion of the Site (Figure 3.1-1). The till was described as very dense, gray-brown, silty-gravelly sand, which occurred between depths of approximately 37 and 48 feet in the two monitoring well borings. The till has been tentatively identified in at least one other soil boring on the Site (11-B-501), located approximately 1,200 feet southwest of wells MW-22 and MW-27. The high density and higher silt content of the till makes it a weak aquitard upon which perched water has been observed. The discontinuity of the Vashon Till across the Site suggests that it was eroded during the high-energy scouring and deposition of the Steilacoom Gravel, leaving only isolated deposits. If the Vashon Till was eroded during the deposition of the Steilacoom Gravel, the overlying Vashon Recessional Gravel would have been eroded also.

Vashon Advance Outwash

The Advance Outwash was deposited by glacial rivers or streams during advance of the Vashon glaciation. The Advance Outwash can be divided into Advance Gravel and the underlying Esperance Sand (formerly known as Advance Sand). This sequence of soil types (becoming finer-grained with depth) is typical of advance outwash deposition.

The Advance Gravel unit of the Vashon Drift occurs beneath the Steilacoom Gravel and is difficult to differentiate from the overlying Steilacoom Gravel. The deposits are described as light brown to gray, slightly silty to non-silty, stratified sands and gravels; however, the Advance Gravels are generally not as coarse-grained as the overlying Steilacoom Gravel.

The Esperance Sand unit was observed beneath the Advance Gravel in some borings and consists of dense, slightly gravelly to gravelly, non-silty to silty, coarse to fine sand. Silty, fine sand encountered in MW-20 and MW-21 appears to represent the lower portion of the Esperance Sand, and the bottom of the Advance Outwash sequence; however, this material may also represent a sandier facies within the DBD-OB sequence (Borden and Troost, 2001).

Olympia Beds/Possession Drift/Whidbey Formation/Double Bluff Drift Sequence

Generally, the DBD-OB sequence is a fine-grained, regionally extensive, interglacial deposit, which separates the glacial deposits of the Vashon Drift and Salmon Springs Glaciation. Five on-site borings were drilled to the top of the DBD-OB sequence, and one of these (MW-18) was

drilled through the formation to the underlying Sea Level Aquifer within the Salmon Springs Glaciation. The DBD-OB sequence has a variable composition of interbedded sand and silts, typical of interglacial deposits. Materials observed in the DBD-OB sequence include stiff to hard, brown, gray, and black silt, sandy silt, and peat, interbedded with silty sand.

Drilling information from Fort Lewis (located north of the Site) confirms that the DBD-OB sequence is a thick (ranging from approximately 70 to 100 feet), very heterogeneous formation generally consisting of a thick organic silt and peat unit with abundant interbedded sand and gravel layers (Woodward-Clyde 1990). Other regional data, including drilling of the Bell Hill water supply wells east of the Site (Hart Crowser 1988b; Hart Crowser 1990), confirm the general character and thickness of the DBD-OB sequence and indicate that the unit is regionally continuous.

Data from the RI drilling program support the general electromagnetic (EM) geophysical interpretation that the top of the DBD-OB sequence has significant structural relief (Hart Crowser 1992c). The topographic relief of the upper surface of the DBD-OB sequence (defined as the first occurrence—upper contact—of stiff silt) may be the result of differences in the deposition of the interglacial sediments comprising the DBD-OB sequence, and/or subsequent scouring of the surface during glacial deposition of the overlying Vashon Outwash.

The geophysical data suggest that the DBD-OB sequence occurs at higher elevations, forming a structural bench in the west-central part of the Site beneath part of Area 18. The drilling data generally confirm this interpretation. The top of the DBD-OB sequence was encountered at an elevation of approximately 130 feet in MW-18, located within Area 18 (Figure 3.1-1), which is higher than in any other boring on the Site. The DBD-OB sequence was observed at elevations ranging from approximately 70 to 110 feet in the four other borings in which it was encountered on the Site (MW-11, MW-17, MW-20, and MW-22). MW-18, which was advanced through the DBD-OB sequence, defined the bottom of the formation at an elevation of 55 feet (formation thickness of approximately 75 feet).

Olympia Beds/Possession Drift/Whidbey Formation/Double Bluff Drift Sequence "Cutoff"

The DBD-OB sequence is not present west of a line located up to 2,500 feet inland from Puget Sound and oriented roughly parallel to the shoreline in this region. The line representing the western extent of the formation has been informally termed the "Cutoff" (formerly known as the Kitsap Cutoff) for this study. Data from numerous soil borings and several EM geophysical survey lines were compiled to infer the location of the "Cutoff" across the Site, as shown in Figure 3.1-1. The thickness of the DBD-OB sequence appears to decrease at its western margin due to erosion during the deposition of the Vashon Outwash and/or Steilacoom Gravel (Figure 3.1-2).

A potential paleochannel within the DBD-OB sequence may have been encountered during the drilling of MW-21 in the central portion of the Site (Figure 3.1-1). The boring was advanced through silty sand to an elevation of 50 feet msl without encountering a competent silt unit, which is generally indicative of the DBD-OB sequence . A thin silt layer was indicated based on drill action at a depth of 125 feet, but no sample was retrieved due to the heaving conditions (borehole collapsing). Although this apparent silt lens occurred at an elevation of approximately 90 feet msl and is in the range of DBD-OB sequence elevations observed elsewhere on the Site, it does not appear to be a remnant of the DBD-OB sequence because the silty sands above and

below it were essentially identical. The sand became finer-grained and more silty with depth, which is typical of Advance Outwash deposition.

These drilling observations also support the general interpretation of the geophysical survey data, which suggest that such a paleochannel may have been eroded into the DBD-OB sequence in this general vicinity (see Figure 4 in Hart Crowser 1992c). As a result of these observations, the inferred trace of the "Cutoff" has been extended to the east of MW-21 (as shown in Figure 3.1-1). The potential paleochannel is discussed below in relation to the Water Table Aquifer.

Salmon Springs Glaciation

The Salmon Springs Glaciation (formerly known as the Salmon Springs Formation) was deposited in the glacial period preceding the DBD-OB sequence interglacial. The formation is relatively heterogeneous and consists of dense, brown, fine sand, and dense, brown, gravelly sand with gravel interbeds. The top of the formation was encountered at a depth of 163 feet (elevation 55 feet msl) in MW-18. Regional information indicates that the formation is on the order of 70 to 120 feet thick and contains zones of organic silt and till in some locations, possibly suggesting deposition in two glacial periods separated by a minor interglacial event (Noble 1990). The Sea Level Aquifer, a regionally extensive aquifer, occurs within the Salmon Springs Glaciation. Some authors refer to this aquifer as the Flett Creek Unit (Noble 1990).

3.1.2 Site Hydrogeology

The hydrogeologic system beneath the Site includes two aquifers: the shallow unconfined aquifer (Water Table Aquifer) in the Vashon Drift sediments, and the deeper Sea Level Aquifer in the Salmon Springs and (west of the "Cutoff") Steilacoom Gravel sediments. In addition, seasonally perched groundwater was encountered at the Site, as discussed below.

The Sea Level Aquifer occurs locally in the immediate Site area under both semiconfined and unconfined conditions (as discussed below). Regionally, however, this aquifer occurs under confined conditions to the east of the Site. The DBD-OB sequence acts as an aquitard (Aquitard) separating the aquifers. Along the western portion of the Site, to the west of the "Cutoff", a single aquifer (unconfined portion of the Sea Level Aquifer) is present.

Perched Groundwater

A zone of perched groundwater was encountered at a depth of approximately 40 feet during February 1992 drilling of monitoring wells MW-22 and MW-27. These wells are located within 50 feet of each other in the western portion of the Site (Figure 3.1-1). Well MW-27 was installed for monitoring and sampling of the perched groundwater.

The groundwater appears to be perched on an 8- to 10-foot-thick lens of till-like material, which may be Vashon Till. The till-like material was also observed during drilling soil boring 11-B-501, located approximately 1,200 feet southwest of the two wells. Monitoring suggests that this perched water is transient, disappearing during the dry summer and autumn months. Approximately 6 inches of water remained in MW-27 during the June 1992 water sampling round. The well then remained dry until the December 1992 sampling round, when it again contained less than 1 foot of water. Continued monitoring through 1993 confirmed the

disappearance of the perched water in late summer and autumn. During sampling, the well always bailed dry and recovered exceedingly slowly, indicating that the silty till material is of relatively low permeability and that the zone of saturation is limited.

Possible perched groundwater was encountered between depths of approximately 20 and 35 feet in the deep RI soil boring (7-B-503) completed within the bottom of the Area 7 kettle. No competent silt unit was encountered in this boring to act as a significant perching unit. A well (7-B-503) was completed within the zone of saturation. Similar to well MW-27, this well bailed dry during sampling and subsequent water level recovery was extremely slow, suggesting that the perched water may be discontinuous. However, unlike at MW-27, the 7-B-503 monitoring well has been dry since its initial sampling in July 1992. Other borings completed within the bottoms of the kettles encountered some zones of saturation (discussed in Sections 2.5, 2,9, and 2.12), but they were discontinuous within borings (vertically) and laterally between borings within each kettle. These observed zones may have been infiltrating wetting fronts rather than perched zones of groundwater. Monitoring well 7-B-503 and the (dry) monitoring wells installed in the Area 16 and 26 kettles (16-B-501 and 26-B-503, respectively) are shown in Figure 3.1-1.

Water Table Aquifer

The Water Table Aquifer occurs within the saturated portion of the Vashon Glacial Drift (both Steilacoom Gravel and Advance Outwash) and receives recharge from infiltration of precipitation through permeable overlying soils. The water table in this aquifer is encountered at depths ranging from approximately 20 to 30 feet below ground (elevations of 190 to 200 feet msl) in the eastern portion of the Site up to approximately 110 to 120 feet below ground (elevations of 90 to 110 feet) near its western extent at the "Cutoff".

Groundwater in the Water Table Aquifer generally flows to the west-northwest, toward Puget Sound. At the "Cutoff", the Water Table Aquifer discharges into the Steilacoom Gravel. As shown schematically in Figure 3.1-2, groundwater from the Water Table Aquifer flows over the edge of the Aquitard and mixes with groundwater flowing in the unconfined portion of the Sea Level Aquifer. Figures 3.1-4, 3.1-5, and 3.1-6 are elevation contour maps (April, August, and December 1992, respectively) for the water table surface in both the Water Table Aquifer and the Sea Level Aquifer west of the "Cutoff" (i.e., a map of the continuous water table surface across the two aquifers). These monitoring rounds include the most comprehensive set of water level measurements. The figures demonstrate the very steep water table gradient present along the "Cutoff". This hydrogeologic situation has also been documented to the north of the Site (Woodward-Clyde 1990).

In the vicinity of Sequalitchew Creek on the Site, the Water Table Aquifer discharges into the creek (Figures 3.1-4, 3.1-5, and 3.1-6) and reaches Puget Sound as surface water. The water table elevation contour maps suggest a subtle groundwater divide, or area in which groundwater flows horizontally in more than one direction, from Old Fort Lake west to the "Cutoff". The higher groundwater elevation near Old Fort Lake (the lake level is an expression of the water table) may indicate recharge to the aquifer from the lake. The divide appears to extend west of the lake, with resulting groundwater flow to the northwest and to the west-southwest (Figures 3.1-4, 3.1-5, and 3.1-6). The presence of the groundwater divide may also suggest a possible

structural high on the Aquitard surface in this area, as discussed in Section 3.1.1 (higher groundwater elevation because of a higher underlying aquitard surface).

Water table elevation data from monitoring wells near Area 31 north of Sequalitchew Creek (MW-7, MW-8, MW-9, and MW-24) and creek elevation data from adjacent staff gauge SG-4 indicate a groundwater divide in this area. From the center of the divide, the water table slopes steeply toward the creek (south), resulting in groundwater flow toward Sequalitchew Creek.

Further to the north, groundwater flows almost parallel to the creek (Figures 3.1-4, 3.1-5, and 3.1-6). Regional information indicates groundwater flows toward the west-northwest in the Water Table Aquifer north of the Site (Woodward-Clyde 1990).

Seasonally, there is little change in the groundwater flow directions in the Water Table Aquifer, as indicated by the groundwater flow direction maps presented in Figure 3.1-4 (April 1992), Figure 3.1-5 (August 1992), and Figure 3.1-6 (December 1992). The water table generally responds uniformly to seasonal precipitation changes, resulting in little change in the directional flow of groundwater. The data do indicate a slightly higher gradient in the Water Table Aquifer beneath Area 31 (immediately north of Sequalitchew Creek) toward the creek during the wetter spring months. The creek elevation at staff gauge SG-4 remained essentially constant while the water table elevations around it fell from the wet (April) to dry (August through December) seasons, resulting in a lower gradient toward the creek in the dry season (Figures 3.1-4, 3.1-5, and 3.1-6). Seasonal changes in surface water elevations are discussed in Section 3.1.3.

Figure 3.1-7 presents hydrographs for selected Water Table Aquifer monitoring wells over a 4-year period of monitoring (1988 through 1992). The hydrographs indicate that the aquifer responds fairly uniformly to seasonal changes, with fluctuations on the order of 3 to 8 feet. No long-term trends are apparent from the data (e.g., long-term decline due to drought).

The thick silt unit typically associated with the Aquitard was not encountered to an elevation of approximately 50 feet msl during drilling of MW-21. Very silty to silty, fine sand was encountered in the elevation range (approximately 50 to 100 feet msl) where hard silt and some peat was encountered in other on-site borings (e.g., MW-18, MW-20, and MW-22). This finding suggests a possible paleochannel incised within the DBD-OB sequence in this general location, as discussed above. Figure 3.1-3 presents the interpretation of subsurface conditions from south to north across this potential paleochannel. The profile location is shown in Figure 3.1-1.

The silty, fine sand is interpreted to represent the lower portion of the Vashon Advance Outwash rather than a sandy facies within the DBD-OB sequence. Although the depositional origin of these materials may vary, the water table elevation in MW-21 is consistent with measured elevations in other wells in the vicinity, indicating that the silty sand supports the Water Table Aquifer above it. Because a thick competent silt unit does not appear to be present within this potential paleochannel, downward flow of groundwater from the Water Table Aquifer may be greater in this area than elsewhere across the Site where the silt is present. However, the water level data do not indicate preferential flow toward the paleochannel; that is, the data do not indicate that the area is a significant groundwater sink (Figures 3.1-4, 3.1-5, and 3.1-6).

Aquitard

Across most of the Site, a low-permeability unit within the DBD-OB sequence(Aquitard) hydraulically separates the Water Table Aquifer from the underlying Sea Level Aquifer. The

"Cutoff", as discussed above, represents the western extent of the Aquitard. This line is also the western extent of the Water Table Aquifer and is where the Sea Level Aquifer changes from semiconfined conditions (beneath the Aquitard to the east) to unconfined conditions (to the west).

As discussed in Section 3.1.1, site-specific and regional information indicate that the Aquitard acts as a regionally extensive low permeability unit within the DBD-OB sequence between the Water Table and Sea Level Aquifers. A difference in hydraulic head (water table elevation) of greater than 100 feet is observed in on-Site wells completed above and below the aquitard unit (e.g., MW-22 and MW-18, respectively).

Sea Level Aquifer

The Sea Level Aquifer is divided into two distinct portions: the portion occurring east of the "Cutoff" and the portion west of it.

East (upgradient) of the "Cutoff", the Sea Level Aquifer occurs within permeable deposits of the Salmon Springs Glaciation, which are encountered immediately below the Aquitard at depths of 150 to 170 feet below ground. Regionally confined conditions exist within this portion of the aquifer (Hart Crowser 1988b; Hart Crowser 1990; Woodward-Clyde 1990). Near the "Cutoff", the artesian pressure dissipates and the Sea Level Aquifer becomes unconfined (water table conditions exist [e.g. MW-18]). Therefore, the Sea Level Aquifer east of the "Cutoff" is referred to as a semiconfined aquifer.

West (downgradient) of the "Cutoff", the unconfined Sea Level Aquifer occurs within the saturated portion of the thick deltaic sequence of the Steilacoom Gravel. Although the Steilacoom Gravel is the youngest unit within the Vashon Drift, it is differentiated hydrostratigraphically because of its unique (coarse-grained and highly permeable) lithology and its hydrogeologic significance within the Site. The water table within the unconfined Sea Level Aquifer is encountered at depths of 160 to 200 or more feet below ground (elevations from approximately 40 feet to less than 5 feet msl).

The Steilacoom Gravel is in direct contact with Vashon Drift, the Aquitard, and the Salmon Springs Glaciation (as shown in Figure 3.1-2). Therefore, the unconfined Sea Level Aquifer receives discharge from both the Water Table Aquifer and the semiconfined Sea Level Aquifer east of the "Cutoff". Water from the two aquifers mixes within the unconfined Sea Level Aquifer (Steilacoom Gravel) and discharges toward the west. The unconfined Sea Level Aquifer discharges to Puget Sound as seeps observed along the shore (such as SEEP 1 and SEEP 2 in Figure 3.1-1) and presumably beneath sea level, where the deltaic deposits terminate in Puget Sound.

Groundwater and surface water elevation data collected during the RI suggest that the lower reach of Sequalitchew Creek loses water to the unconfined Sea Level Aquifer. This is consistent with the high infiltration capacity of the gravels observed at the base of the drainage. As shown in Figure 3.1-4, the April 1992 creek elevation at SG-1 is at least 4 feet higher than water table elevations in either of the nearest wells completed in the unconfined Sea Level Aquifer (MW-1 and MW-15), indicating flow from the creek to the aquifer. No springs have been observed along the creek anywhere within this relatively flat stretch of creek valley. The creek was dry at SG-1 from August 1992 through January 1993, indicating that, at low summer/autumn creek

flows, all creek flow discharges to the unconfined Sea Level Aquifer. In the vicinity of SG-2 farther up the creek, the groundwater and surface water elevation data are less conclusive, but it appears that the creek is also losing to the aquifer in this area. The water level data indicate that, in general, the creek is gaining (receiving recharge) from the Water Table Aquifer east of the 'Cutoff" (upper portion of the drainage).

The Sea Level Aquifer east of the "Cutoff" receives recharge principally from infiltration of precipitation in areas east of the Site. The Sea Level Aquifer west of the "Cutoff" receives additional recharge from groundwater flowing from the Water Table Aquifer and semiconfined portion of the Sea Level Aquifer, as well as from infiltration of precipitation through the overlying unsaturated Steilacoom Gravel.

Figure 3.1-8 presents hydrographs for selected Sea Level Aquifer monitoring wells for the period 1988 through 1992. As with the Water Table Aquifer, the hydrographs indicate that the water table in the Sea Level Aquifer responds fairly uniformly to seasonal changes, particularly near Puget Sound. Nearer the "Cutoff", there is greater difference in the responses between wells (e.g., MW-4 and MW-6), which is not unexpected considering the nature of the water table surface as it crosses the "Cutoff". Water table elevation fluctuations in the Sea Level Aquifer are only 2 to 3 feet less than the 3- to 8-foot fluctuations observed in the Water Table Aquifer. No long-term water level trends are apparent for the Sea Level Aquifer.

Because the Sea Level Aquifer is in hydraulic connection with Puget Sound, a natural saltwater/freshwater mixing zone is present along the western margin of the aquifer. Over the period of monitoring, total dissolved solids (TDS) ranged from approximately 10,000 to 16,000 mg/L in SEEP 1 and SEEP 2, which discharge from the Sea Level Aquifer (Figure 3.1-1). These elevated TDS values are indicative of discharge from the saline mixing zone. The TDS values for Sea Level Aquifer monitoring wells MW-16 and MW-19, located within approximately 400 feet of Puget Sound, are generally less than 200 mg/L, which is similar to values from the other on-Site monitoring wells located farther inland. These data indicate that the mixing zone is not extensive, extending inland less than 400 feet.

Hydraulic Conductivity Testing of Aquifers

Data from two in situ testing methods (variable-head tests [i.e., slug tests] and short-term pumping tests) and laboratory grain size analyses of aquifer materials were evaluated to provide estimates of saturated hydraulic conductivity for the Water Table and Sea Level Aquifers. The short-term pumping tests were conducted in on-Site monitoring wells using a 2-inch submersible pump. In addition, hydraulic conductivity estimates from regional hydrologic reports were used to further refine a reasonable range of hydraulic conductivity values for the aquifers. Hydraulic conductivity estimates from Site-specific and regional data for the three aquifers (Water Table, unconfined Sea Level, and semiconfined Sea Level Aquifers) are summarized in Table 3.1-1.

Table 3.1-2 provides the hydraulic conductivity values estimated by application of the Kozeny-Carmen equation (Freeze and Cherry 1979) to grain size data for samples of aquifer materials. The analyses assumed a range of porosity values of 0.20 to 0.35, which is reasonable for the range of aquifer materials at the Site.

Water Table Aquifer

Site-specific hydraulic conductivity (K) estimates for the Water Table Aquifer ranged from 2 x 10^{-3} to 7 x 10^{-2} cm/sec and were derived from five slug tests and two short-term pumping tests conducted in on Site monitoring wells as part of the RI (Table 3.1-1). The geometric means of six estimates from the Kozeny-Carmen equation (Freeze and Cherry 1979) were 5 x 10^{-1} and 4 cm/sec, corresponding to assumed porosities of 0.20 and 0.35, respectively (Table 3.1-2).

Regional estimates of Water Table Aquifer hydraulic conductivities range from 4 x 10^{-3} to 2 x 10^{-2} cm/sec, based on pumping test results from City of DuPont Well No. 1 (Associated Earth Sciences 1984) and test well PW-1A at Fort Lewis (Woodward-Clyde 1990).

The range of hydraulic conductivity values is reasonable considering the different lithologies comprising the Water Table Aquifer—highly permeable Steilacoom Gravels to fine sand in the lower horizons of the Advance Outwash. Because of the slope of the water table and the general fining-downward (decrease in grain size with depth) sequence of the aquifer materials, the average hydraulic conductivity of the Water Table Aquifer may decrease somewhat from the east (saturated Steilacoom Gravel) to the west (saturated Advance Outwash deposits) across the Site. Although the data are variable, the hydraulic conductivity estimate from MW-22 near the "Cutoff" are somewhat lower than estimates from wells to the east (e.g., MW-7 and MW-12), lending some support to this hypothesis. However, different testing methods (e.g., short-term pumping tests versus slug tests) may also contribute to the differences in the estimates.

The available data presented in Table 3.1-1 suggest that a reasonable range of hydraulic conductivities for the Water Table Aquifer is 5 x 10^{-3} to 5 x 10^{-2} cm/sec. This range is referred to in Table 3.1-1 as the Best Estimate Range.

Semiconfined Sea Level Aquifer (East of Kitsap Cutoff)

Reported values of hydraulic conductivity (K) for the Sea Level Aquifer east of the "Cutoff" are in the range of 6 x 10^{-3} to 5 x 10^{-2} cm/sec, based on results from two pumping tests performed in Bell Hill Well No. 1 (Hart Crowser 1988b; Hart Crowser 1990), and pumping tests conducted in Weyerhaeuser Well No. 3 and Fort Lewis Well No. 18 (Associated Earth Sciences 1984). A slug test performed in monitoring well MW-18 produced an estimated K of 4 x 10^{-3} cm/sec, which is lower than the values from the pumping tests.

These results suggest that a reasonable range of hydraulic conductivities for the semiconfined Sea Level Aquifer is from 1 x 10^{-2} to 5 x 10^{-2} cm/sec (Table 3.1-1).

Unconfined Sea Level Aquifer (West of "Cutoff")

Slug tests conducted in monitoring wells completed in the unconfined Sea Level Aquifer produce K estimates ranging between 2 x 10^{-3} to 2 x 10^{-2} cm/sec. The slug test results may be biased low due to the influence of the wellbore sandpack materials, which may actually have lower in situ permeability than the native (undisturbed) aquifer materials. Hydraulic conductivity estimates from grain size data of the Steilacoom Gravel aquifer materials range from 2 x 10^{-2} to 1 cm/sec (Table 3.1-2). Woodward-Clyde (1990) reported a range of hydraulic conductivities for the unconfined Sea Level Aquifer of 4 x 10^{-1} to 4 cm/sec, based on literature values.

It should be noted that based on available information, pumping tests have not been conducted within the unconfined Sea Level Aquifer (west of "Cutoff") in the region. As a result, hydraulic conductivity estimates for this aquifer are developed from the slug tests and grain size data, and from regional studies also evaluating grain size characteristics. On the basis of these data and the uncertainty associated with them, a reasonable hydraulic conductivity range for the unconfined Sea Level Aquifer is 1×10^{-2} to 1 cm/sec (Table 3.1-1).

Groundwater Flow Rates in the Aquifers

A range of horizontal groundwater flow rates within the Water Table and Sea Level Aquifers is estimated using the Best Estimate Range of hydraulic conductivity values (Table 3.1-1), horizontal hydraulic gradient estimates developed from the April 1992 water table elevation contour map (Figure 3.1-4), and an assumed effective porosity of 0.25. The groundwater flow rates for each aquifer are estimated by applying Darcy's Law of the form:

$$v = K I / n$$

where:

v = average linear groundwater velocity in feet/day
K = horizontal hydraulic conductivity in feet/day
I = horizontal hydraulic gradient in feet/foot
n = effective porosity (dimensionless)

Because of differences in hydraulic gradient across the Site, Darcy's Law is applied between two points. The flow rates reported below apply between these points.

Water Table Aquifer

Using the April 1992 data (Figure 3.1-4), the hydraulic gradient between the 190-foot water table elevation contour and MW-23 north of Sequalitchew Creek (measured perpendicular to the contours) is approximately 0.05 foot/foot. For a range of hydraulic conductivity of 14 to 140 feet/day (5×10^{-3} to 5×10^{-2} cm/sec), the estimated groundwater flow rate between these two points is approximately 3 to 28 feet/day (approximately 1,000 to 10,000 feet/year).

South of the creek, the April 1992 hydraulic gradient is calculated to be approximately 0.02 foot/foot between three pairs of points: (1) between the 200-foot water table elevation contour and MW-21, (2) between Old Fort Lake and MW-17, and (3) between Old Fort Lake and MW-22 (Figure 3.1-4). Therefore, the estimated groundwater flow rate determined between these sets of points ranges from approximately 1 to 22 feet/day (approximately 400 to 8,200 feet/year) using the range of Water Table Aquifer K estimates.

As discussed above, water table elevations gradually dropped during the summer and autumn months, generally resulting in a flatter water table and slightly lower hydraulic gradients toward discharge points. The lower gradients (5 to 20 percent lower in December than April 1992) result in correspondingly lower groundwater velocities.

Unconfined Sea Level Aquifer

Because the gradient flattens abruptly west of the "Cutoff", gradients and resulting groundwater flow rates were calculated between MW-3 and Puget Sound (assumed aquifer discharge at elevation 0 msl), and between MW-6 and Puget Sound. The hydraulic conductivity range of 1 x 10^{-2} to 1 cm/sec (28 to 2,800 feet/day) was used for the groundwater flow rate estimates (Table 3.1-1).

Using April 1992 data, a gradient of 0.005 foot/foot is calculated between MW-3 and Puget Sound, resulting in estimated groundwater flow rates ranging from approximately 0.6 to 60 feet/day (approximately 200 to 20,000 feet/year). For a gradient of 0.02 foot/foot calculated between MW-6 and Puget Sound, flow rates range from approximately 2 to 200 feet/day (approximately 800 to 80,000 feet/year). Consistent with the Water Table Aquifer, estimated groundwater velocities in the Unconfined Sea Level Aquifer were typically 5 to 20 percent lower in December 1992 than in April 1992, due to lower gradients.

Semiconfined Sea Level Aquifer

The groundwater flow rate in the semiconfined Sea Level Aquifer is estimated between MW-18 and Puget Sound. The water table elevation in MW-18 was 5.07 feet msl in the April 1992 round of measurements, resulting in a gradient toward Puget Sound of 0.003 foot/foot. Therefore, a range of groundwater flow rates of approximately 0.3 to 2 feet/day (approximately 120 to 600 feet/year) are estimated using the range of K estimates for the Sea Level Aquifer presented in Table 3.1-1. Estimated groundwater velocities in the semiconfined Sea Level Aquifer were approximately 10 percent lower in December 1992 than in April 1992 because of lower gradients.

However, because groundwater discharges from the semiconfined Sea Level Aquifer into the unconfined Sea Level Aquifer across most of the Site (except along the southwest corner in the vicinity of MW-17), groundwater flow rates calculated between MW-18 and Puget Sound may not be representative of gradients encountered east (upgradient) of the "Cutoff".

A second range of flow rates for the Sea Level Aquifer is estimated on a more regional scale by applying Darcy's Law between Bell Hill No. 1 and MW-18, a distance of approximately 10,000 feet. This estimate accounts for the change from confined to unconfined conditions within the aquifer. The water level elevation in Bell Hill No. 1 is approximately 75 feet msl, resulting in an average regional gradient of approximately 0.007 foot/foot between it and MW-18. Applying the K range above results in groundwater flow rates ranging from approximately 0.8 to 4 feet/day (approximately 300 to 1,400 feet/year).

Estimate of Vertical Flow Through the Aquitard

Hydraulic Conductivity Testing of the Aquitard. Two undisturbed samples of the Kitsap Aquitard were collected and tested in Hart Crowser's geotechnical laboratory using flexible-wall permeameter methods. A vertical hydraulic conductivity value of 8 x 10^{-7} cm/sec was obtained from laboratory testing of a sample of the aquitard material (MW-20, S-24). The first attempt to collect an undisturbed sample of the aquitard material (from MW-22) using a Shelby tube was unsuccessful. After the Shelby tube was driven into the very stiff silt (too stiff for the tube to be pushed), the pins attaching it to the drill rods snapped during the retrieval attempt. The Shelby

tube remained in the bottom of the borehole, preventing further sampling efforts. No cohesive soils suitable for laboratory K testing were encountered during drilling of MW-21.

Vertical Gradients

Stratigraphic and water level data from MW-18 in the Sea Level Aquifer beneath the Aquitard indicate that the aquifer is unconfined, with the water table more than 50 feet below the aquitard bottom. The vertical gradient across the aquitard is estimated by dividing the combined thickness of the Water Table Aquifer and Aquitard (assumed saturated) by the thickness of the aquitard. To be conservative, the thickness of the Water Table Aquifer observed at MW-20 (45 feet) is used rather than the thickness measured at MW-22 (less than 15 feet), closer to the "Cutoff". Using this 45-foot aquifer thickness and the aquitard thickness observed in MW-18 (75 feet), a downward gradient of approximately 1.6 feet/foot across the aquitard is calculated.

Where the Sea Level Aquifer becomes confined farther to the east, the vertical gradient would be smaller. Therefore, the vertical gradient calculated from the existing data produces a "worst-case" (i.e., maximum) estimate of downward flow through the aquitard.

Rate of Downward Flow

The rate of downward flow across the Aquitard is estimated by applying Darcy's Law, as defined above, vertically across the aquitard. Using the estimated downward gradient of 1.6 feet/foot, the geometric mean of the laboratory vertical K values (3×10^{-7} cm/sec = 0.3 feet/year), and an assumed porosity of 0.4 (rounded from 0.37 for stiff glacial clay from Terzaghi and Peck 1948), results in an estimated advective flow rate through the aquitard of approximately 1 foot/year.

3.1.3 Surface Water Features

Three surface water bodies (Puget Sound, Sequalitchew Creek, and Old Fort Lake) occur within or near the Site (Figure 3.1-1).

Puget Sound

Puget Sound borders the west boundary of the Burlington Northern Railroad property, which is below the bluff at the Site. Puget Sound directly or indirectly receives groundwater and surface water discharge from the Site vicinity.

Sequalitchew Creek

Sequalitchew Creek, which flows through the northern portion of Parcel 1 at the Site, originates in Sequalitchew Lake, approximately 1.4 miles to the east of the property. The creek flows westward through Hamer Marsh and Edmonds Marsh east of the Site before flowing within a steep-sided ravine that descends to Puget Sound. The Water Table Aquifer locally discharges into the creek via springs. The creek appears to provide some recharge to the unconfined Sea Level Aquifer in its lower reaches, as discussed above.

The upper and lower reaches of the stream are intermittent, becoming dry in the summer months. Visual observations indicate that during the dry season, when there is little freshwater flow in the lower reaches of Sequalitchew Creek, Puget Sound backs up into the creek valley at high tide.

The creek was also dry along the eastern margin of the Site (at staff gauge SG-5) between August 1992 and January 1993, indicating that the water table elevation was below the creek bottom. Water was typically observed in the creek 150 to 200 feet downstream of SG-5 during these dry months. Between staff gauges SG-4 and SG-2, the creek bed is below the water table elevation throughout the year; therefore, the creek maintains water in this stretch year round.

Old Fort Lake

Old Fort Lake is a small glacial kettle lake, which has no inlet or outlet. The shallow lake is fed by groundwater from the Water Table Aquifer, and the lake level is an expression of the water table. Data collected between April 1992 and July 1993 indicate that the lake level fluctuates seasonally approximately 8 feet.

3.2 GROUNDWATER QUALITY CHARACTERIZATION

3.2.1 Groundwater Sampling Conducted to Date

Site groundwater quality assessment began at the Site during the pre-RI site characterization with sampling of the three spring locations and seven surface water locations in December 1986. As part of the initial hydrologic and water quality assessment in late 1987 and early 1988, 17 monitoring wells were installed in the Water Table Aquifer (MW-7 through MW-14, and MW-17) and the Sea Level Aquifer (MW-1 through MW-6, MW-15, and MW-16). Groundwater quality was evaluated in March 1988 by sampling and analysis of 15 monitoring wells, 3 springs, and 3 on-Site fire protection wells. During this first round of sampling, constituents identified in groundwater samples were detected at low concentrations, and a quarterly monitoring program was recommended to provide a basis to assess possible temporal or seasonal changes in groundwater quality. Three quarterly sampling rounds were conducted in June 1988, October 1988, and January 1989; results from these sampling rounds are summarized in Hart Crowser 1988c, 1988d, and 1989a, respectively.

Following installation of two additional monitoring wells (MW-18 and MW-19) in November 1989, interim sampling rounds were conducted in November 1989 (Hart Crowser 1990) and August 1990 (Hart Crowser 1991c).

Four additional monitoring wells (MW-20, MW-21, MW-24, and MW-27) were installed, followed by four quarterly groundwater and surface water sampling rounds in March, June, September, and December 1992. Twenty-seven monitoring wells, one spring discharging to Sequalitchew Creek, two sea-level seeps discharging to Puget Sound, and five surface water locations were sampled during the RI (35 combined groundwater and surface water locations). In addition, six off-Site wells were sampled to provide background groundwater quality data.

A supplementary sampling round was conducted in January 1993 to collect four sets of water quality data ("four usable data points" criterion discussed below). During this round, attempts were made to sample all groundwater and surface water sampling locations where four complete sets of water quality data had not been collected due to seasonally dry conditions.

In addition to groundwater sampling outlined in the Management Plan, quarterly groundwater sampling for DNT was continued from April 1993 through October 1997 at seven selected monitoring wells (MW-3, MW-6, MW-8, MW-15, MW-19, MW-22, and MW-27) and SEEP-1. In January 1996, two fireline wells (W-1 and W-2) were added to the quarterly sampling program. One additional fireline well (W-3) was sampled during two rounds.

After October 1997 and authorization from Ecology, the groundwater monitoring locations and frequency of sampling were reduced. Since then, three additional rounds of annual DNT groundwater sampling have occurred at four selected monitoring wells (MW-3, MW-6, MW-19, and MW-22) and fireline well W-2. The annual DNT groundwater sampling will be continued as required in the final CAP.

Table 3.2-1 summarizes groundwater sampling (by location) conducted to date.

Four Usable Data Points Criterion

As discussed in the Management Plan, the goal of the RI groundwater and surface water sampling program was to obtain four usable data points (adequate detection limits and sufficient data quality) for each target constituent identified in the RI/FS Management Plan at each of the 38 groundwater and surface water sampling locations. Both the pre-RI data and data collected during the RI were considered in determining the number of usable data points. During the first two rounds of RI water sampling, all locations were sampled for all target constituents. At the end of the two rounds, the existing pre-RI and RI data were evaluated to determine which locations required additional sampling for specific constituents.

As stated in the Management Plan, if seasonally dry conditions prevent the collection of an adequate number of samples (over five rounds of RI sampling) to achieve four usable points at each location, the available data would be evaluated to determine the necessity of additional sampling.

In general, four usable water quality data points for each target constituent were achieved at each sampling location, with the exception of some of the springs in the Sequalitchew Creek valley, and monitoring wells completed in zones of seasonally (transient) perched water.

Although four usable data points were achieved after only two RI sampling rounds for some constituents (e.g., DNT and nitrate) at several locations, NAX and nitrate analyses were continued through the January 1993 sampling rounds to provide additional data for evaluating potential concentration trends over time. The subsequent quarterly sampling rounds beginning in April 1993 were also conducted for this purpose (NAX only). Table 3.2-2 presents the number of usable data points (analyses) for each constituent at each location collected over 32 rounds of combined pre-RI and RI water sampling covering 12 years (1988 through 2000).

RI Groundwater Quality Sampling Locations

Thirty locations were sampled during the pre-RI and RI for Parcel 1 inside the CDB (Figure 3.1-1):

- Twelve Water Table Aquifer monitoring wells (MW-7, MW-8, MW-9, MW-11, MW-12, MW-13, MW-14, MW-17, MW-20, MW-21, MW-22, and MW-24)

- Ten Sea Level Aquifer monitoring wells (MW-1, MW-2, MW-3, MW-4, MW-5, MW-6, MW-15, MW-16, MW-18, and MW-19)
- Two monitoring wells completed in zones of seasonal perched groundwater (MW-27 and 7-B-503)
- One spring discharging from the Water Table Aquifer to Sequalitchew Creek (SPR-4)
- Two seeps discharging from the Sea Level Aquifer to Puget Sound (SEEP 1 and SEEP 2)
- Three fire protection wells (W-1, W-2, and W-3)

Background Water Quality Sampling Locations

Two rounds of groundwater samples were collected from six locations outside the CDB to provide data for evaluation of natural background (upgradient) water quality for the Water Table Aquifer and Sea Level Aquifer. The background wells included City of DuPont Well No. 1, Bell Hill No. 1, Fort Lewis production wells FL-9 and FL-18, and two monitoring wells upgradient of Fort Lewis Landfill No. 5 (88-2-VD and 88-1-SS). City of DuPont Well No. 1, FL-9, and 88-2-VD are completed in the Water Table Aquifer; Bell Hill Well No. 1, FL-18, and 88-1-SS are completed in the Sea Level Aquifer. Available regional data indicate that the Water Table Aquifer and (semiconfined) Sea Level Aquifer at the background (upgradient) well locations are contiguous with these aquifers on the Site. As stated in Management Plan, the unconfined portion of the Sea Level Aquifer does not exist upgradient of the Site; background water quality in this aquifer is represented by both upgradient aquifers (Water Table and semiconfined Sea Level Aquifers). Background samples were collected in June and December 1992.

Constituent Analyses of Groundwater Samples

During the first two rounds of RI sampling, all on-Site groundwater samples were analyzed for the following constituents:

- Nitrate plus nitrite as nitrogen
- TPH (WTPH-418.1)
- Total priority pollutant metals plus aluminum (14 total metals)
- Dissolved priority pollutant metals plus aluminum (14 dissolved metals)
- PAHs
- NAX (TNT, 2,4-DNT, and 2,6-DNT and selected breakdown products including nitrobenzene [NB], 1,3-dinitrobenzene [DNB], and 1,3,5-trinitrobenzene [TNB])
- NG
- MMAN
- Total organic carbon (TOC)
- TDS
- Total suspended solids (TSS)

Selected monitoring wells were sampled and analyzed for OP and OC pesticides, PCBs, VOCs, and SVOCs.

Background water quality samples were analyzed for the following analytes: NAX, nitrate plus nitrite, total and dissolved metals, PAHs, TPH, TSS, TDS, and TOC.

3.2.2 Background Groundwater Quality Results

The following constituents were detected in one or more of the background water quality samples:

- Total and dissolved aluminum
- Dissolved antimony
- Total and dissolved cadmium
- Total and dissolved copper
- Total lead
- Total and dissolved zinc
- Nitrate
- Phenanthrene, a noncarcinogenic PAH (ncPAH)

As stated in the discussion of metals data for groundwater in Section 3.2.3, total metals concentrations are generally higher than dissolved metals concentrations in the same sample due to turbidity present in the unfiltered groundwater samples. The total metals concentrations in samples with elevated TSS do not appear to be representative of groundwater quality.

Background total aluminum detections occurred in samples with nondetectable or low concentrations of TSS. Dissolved aluminum was detected in 5 of the 12 background samples (filtered samples without turbidity). These data indicate that dissolved aluminum is a naturally occurring constituent of groundwater in the area. Aluminum-bearing minerals (such as feldspars and clay minerals) are common rock-forming minerals in the crust of the earth, and aluminum is naturally present at percent levels (greater than 10,000 mg/kg) in the glacial soils of Puget Sound (refer to Section 2.2 for area background soil quality results). As a result, aluminum is also naturally present in regional groundwaters.

During sample filtration, the filter contributed antimony to the dissolved metals samples; therefore, the antimony concentrations in the samples are not representative of groundwater quality, as discussed below.

3.2.3 Constituents in Groundwater

A discussion of the DNT and nitrate data for groundwater, and additional discussions of the metals and PAH data, are provided below. Groundwater quality data tables are provided in Appendix C.

DNT Data for Groundwater

The range of total DNT (2,4-DNT plus 2,6-DNT) concentrations detected since monitoring started in 1986 are as follows:

- MW-3 downgradient of Area 5 (0.07 to 0.56 µg/L)

- MW-6 downgradient of Area 26 (0.02 U to 0.44 µg/L)
- MW-8 downgradient of Area 31 (0.02 U to 0.21 µg/L)
- MW-15 downgradient of Area 5 (0.02 U to 0.16 µg/L)
- MW-19 downgradient of Area 18 (0.07 to 0.63 µg/L)
- MW-22 downgradient of Area 18 (0.05 to 0.87 µg/L)
- MW-27 completed in a zone of seasonally perched water beneath Area 18 (0.11 to 3.8 µg/L)

DNT has been detected only in monitoring wells located downgradient of areas where DNT has been detected in soils (Areas 5, 18, 26, and 31). DNT has not been detected in any other wells.

DNT has been detected in MW-15, but this concentration has not been confirmed in any of the six subsequent sampling rounds.

DNT site data collected since 1986 are summarized in Appendix C.

Evaluation of DNT Concentrations Related to Sample Turbidity

To evaluate potential differences in DNT concentrations between unfiltered samples and filtered samples, additional groundwater samples from two monitoring wells (MW-19 and MW-22) were collected in October 1992. Unfiltered and filtered (through a glass fiber filter) samples were submitted for NAX analyses. In addition, suspended particulate matter collected on the filter was submitted for NAX analysis.

The results of this evaluation indicate no significant difference between DNT concentrations in unfiltered and filtered samples (Appendix C). The measured differences in concentration can be attributed to sampling and analytical variability. Furthermore, no NAX compounds were detected in the filtrate (particulate matter trapped on the filter). These data indicate that DNT is present in the dissolved phase and that sample turbidity does not significantly affect detected DNT concentrations.

Area 18 Seasonally Perched Water

DNT has been detected in MW-27, a monitoring well located next to MW-22 (in Area 18) and completed in a localized zone of perched water that is present only during the wet season. When water was present in this monitoring well (to a maximum saturated thickness of less than 2 feet), the well bailed dry after removal of approximately one casing volume. The water level also recovered extremely slowly after purging (the perched zone occurs upon and within a relatively low-permeability till unit, as discussed in Section 3.1). Because the perched zone is incapable of yielding 0.5 gallon per minute (gpm) on a sustainable basis, it is not a potential drinking water source, in accordance with MTCA [WAC 173-340-720(2)(b)(i)].

SEEP 1

The SEEP 1 sampling location represents discharge to an intertidal beach area from a freshwater/saltwater mixing zone at the edge of the Sea Level Aquifer. Accordingly, the seep discharge is naturally saline (discussed in Section 3.1.2). During the period of monitoring, TDS measurements ranged from 9,600 to 16,000 mg/L, with an average value of 12,700 mg/L. Because TDS concentrations are greater than 10,000 mg/L, SEEP 1 is not a potential drinking water source, in accordance with MTCA [WAC 173-340-720 (2)(b)(ii)]. Similarly, other seeps

along the beach, which are also submerged daily by Puget Sound high tides, would not be considered potential drinking water sources (SEEP 2 north of Sequalitchew Creek has a similar range of TDS).

Total DNT concentrations from SEEP 1 have ranged from nondetection to 0.27 µg/L in the 25 samples collected over the period of monitoring (Appendix C). All detected DNT concentrations at SEEP 1 (pre-RI and RI) are at least 33 times lower than the protective surface water concentration of 9.1 µg/L. Based on this comparison, DNT discharging from Site groundwater via seeps to Puget Sound poses no concern to human health or the environment.

No Seasonal Trends in DNT Groundwater Concentrations

No seasonal trends are apparent in visual examination of the DNT groundwater quality data (Figures 3.2-1 through 3.2-4). Plots of DNT groundwater concentration as a function of groundwater elevation indicated no apparent correlation for any of the seven wells in which DNT has been detected at elevated concentrations (Figure 3.2-5). Groundwater elevation provides a more direct measure of seasonality than time of sampling (for example, April versus October) because groundwater elevations inherently account for recharge lag times, which will vary across the Site.

Summary of DNT Data for Groundwater

Data from 35 rounds of combined pre-RI and RI groundwater sampling at up to 30 locations (1986 through 2001) indicate consistently low DNT concentrations in 6 of 30 Site groundwater monitoring locations. DNT has been detected in groundwater samples from seven Site monitoring wells at marginally elevated concentrations. DNT has been detected only in monitoring wells located downgradient of areas where DNT has been detected at elevated concentrations in soils (Areas 5, 18, and 31). DNT groundwater concentrations do not show statistically significant increases or decreases at this time. The DNT groundwater concentrations may decline over time as a result of the ISR of DNT-containing soils. Because detected DNT concentrations were consistently low, are not affecting the regional aquifer, are not affecting surface water, and the aquifer is not used as a drinking water source, Ecology determined that "no active remedial action" was needed, and long-term monitoring at selected wells would be sufficient. This issue will also be addressed in the Cleanup Action Plan for the Site.

Nitrate Data for Groundwater

Nitrate (expressed as nitrogen) has been detected in monitoring wells MW-6, MW-13, and MW-22. MW-13 is located along the upgradient (eastern) edge of the Site. Elevated nitrate concentrations (e.g., 9.2 mg/L in October 1988) have also been detected at MW-14, also at the upgradient edge of the Site. These data suggest potential nitrate sources upgradient (east) of the Site, such as animal pasturing, which is known to have occurred east of the Site in the past. The nitrate data collected to date for groundwater are provided in Appendix C.

Elevated nitrate concentrations were detected in samples from wells MW-6 in March and April 1988, and MW-13 in March 1988. No nitrate concentrations from these wells have been elevated in any of eight subsequent rounds of monitoring, as shown in Figure 3.2-6. Regression

analyses on the nitrate data indicate that the downward trends at these two wells are statistically significant (95 percent confidence level; p = 0.05).

The nitrate concentrations detected in samples from MW-22 were at approximately 10 mg/L in the June, September, and December 1992 sampling rounds. These data suggest that the nondetection in the March 1992 sample from this well was erroneous, possibly due to sample mislabeling or analytical reporting error (Appendix C). No analytical problems with this result were indicated by full (Level IV) data validation.

Although elevated nitrate concentrations were detected in groundwater samples collected from two monitoring wells in 1988, concentrations in these wells show statistically significant declines. Because elevated nitrate concentrations have been detected in samples from monitoring wells located along the eastern (upgradient) edge of the Site, off-Site sources of nitrate are possible.

Metals Data for Groundwater

With the exception of aluminum, no concentrations of dissolved metals in any groundwater sample were elevated. Of 126 site groundwater samples from 10 wells analyzed for dissolved metals, 14 samples contained elevated concentrations of aluminum. As discussed above, 2 of the 12 background samples had dissolved aluminum concentrations above 0.05 mg/L, indicating that aluminum may be present at this concentration in regional background groundwater. Only 1 of the 126 groundwater samples had concentrations above 0.2 mg/L (0.98 mg/L at MW-8 in September 1992). This single detection appears to be anomalous since it is more than four times higher than any other detection in this well or any other well sampled during the RI.

Concentrations of some total metals (unfiltered samples) were elevated in groundwater samples from selected wells. For the pre-RI and RI data, dissolved concentrations are defined as being filtered through a 0.45-µm filter in the field. All dissolved and total metals data for groundwater are provided in Appendix C.

The consistent difference between total and dissolved metals concentrations indicates that the metals concentrations are associated with particulate matter within the groundwater samples rather than dissolved in the groundwater; i.e., the total concentrations are an artifact of the well installation, development, and sampling methods (bailer use). The monitoring wells were installed in accordance with Chapter 173-160 WAC; however, they cannot be developed sufficiently to provide low-turbidity samples consistently across the Site. Therefore, in accordance with MTCA [WAC 173-340-720 (9)(b)], dissolved metals concentrations are a more representative measure of groundwater quality at the Site.

The following discussion provides a summary of analyses performed to assess the relationship of sample turbidity to detected total metals concentrations. These analyses support the conclusion that the detected total metals concentrations are biased high due to sample turbidity.

Correlation of Total Metals Concentrations and Suspended Sediment (Sample Turbidity)

There is a strong correlation between sample TSS and total metals concentrations in unfiltered groundwater samples collected during the RI. Figures 3.2-7 through 3.2-9 show plots of total metal concentration versus TSS for each metal with elevated detected total concentrations. Although outlier data points exist, the data plots indicate a strong correlation between metals

concentrations and sample turbidity (TSS). The figures also demonstrate that total metals concentrations generally are detected only in samples with elevated TSS (above 100 mg/L).

Calculations were performed using these data plots to estimate what concentrations (order-of-magnitude) in the particulate phase (TSS) would be necessary to produce the observed total metals concentration in the groundwater samples. These particulate concentrations are then compared to background soil quality data for the Site.

The equation used is as follows:

$$\text{particulate concentration (mg/kg)} = \frac{\text{concentration in water (mg/L)}}{\text{TSS (mg/L)}} \times 10^6 \text{ mg/kg}$$

This analysis assumes that the metals desorb completely from the particulate matter during sample digestion for metals analysis.

Regression analyses were conducted on the total aluminum and total lead data (versus TSS). The regression equations were used to calculate a representative TSS value for a given water concentration of interest. Using these water concentrations and calculated TSS values, corresponding particulate concentrations were estimated using the above equation. Note that the same general range of particulate concentrations can be calculated using an "eye-balled" best-fit line through the data, rather than a regression equation.

These calculations suggest that, at these TSS values in the groundwater samples, aluminum concentrations as high as 100 mg/L in water can be the result of particulate (soil) concentrations on the order of 30,000 mg/kg. This soil concentration is only slightly above the range of aluminum concentrations detected in the area background soil samples for the Site. Similarly for the other metals, this evaluation indicates groundwater concentrations could be the result of respective soil concentrations typical of background soils.

Although the numbers calculated using this simple evaluation are approximate, they demonstrate that high total metals concentrations in the groundwater samples can be caused by a high concentration of particulate matter (high TSS) with low concentrations of metals on the particulate matter.

Decreased Total Metals Concentrations Following Monitoring Well Redevelopment

Between the first and second rounds of RI water sampling, the newly installed Water Table Aquifer monitoring wells (MW-20, MW-21, MW-22, and MW-24) were redeveloped using a more vigorous method (air-lift pump) than that previously used (submersible pump) to remove as much turbidity as possible. As a result, concentrations of total metals in these wells generally decreased between the March and June sampling rounds, further supporting the contention that the observed total metals concentrations are the result of sample turbidity. TSS values were again higher in several wells in the September and December sampling rounds, resulting in corresponding increases in total metals concentrations. Although TSS and total metals concentrations varied over time, dissolved metals were consistently not detected in filtered groundwater samples.

Comparison of Monitoring Well and Production Well Construction/Development

Because they are constructed for different purposes, monitoring wells (as sampled in this RI) and production (water supply) wells are designed, constructed, and developed according to substantially different standards. As a result, the turbidity of groundwater collected from Site monitoring wells is not representative of groundwater that would be pumped from a properly installed production well in these same aquifer materials.

The principal purpose of a production well is to provide maximum yield with minimum turbidity, both to prevent the need for filtration and to protect the pump and piping from corrosion. For aesthetic reasons, drinking water supplies are not cloudy (turbid); in fact, a secondary drinking water standard exists for turbidity. To achieve this minimum turbidity, design of a production well is typically detailed, requiring evaluation of the sizing of the well screen and the filter pack (outside the screen) based on the characteristics of the aquifer materials. Construction of the wells includes large-diameter casings to accommodate pumps and increase yield, and often thick filter packs to prevent finer-grained aquifer materials from reaching the well screen. Development of these wells typically takes several days, often involving surging or other techniques. Development is typically completed during a pumping test in which the well is pumped at the expected rate of yield for an extended period (often 24 hours or more). The combination of the intensive development and high-volume pumping is generally successful at removing suspended sediment from the well and filter pack, resulting in water free of turbidity.

On the other hand, the principal purpose of a monitoring well is to provide a groundwater sample, which requires relatively small yield. As a result, the on-Site monitoring wells were constructed of 2-inch-diameter polyvinyl chloride (PVC) with up to 2 inches of filter pack outside the well screen, which is standard for the environmental industry and in accordance with state well construction regulations (Chapter 173-160 WAC). Because the wells have an inside diameter of less than 2 inches, the methods of development are limited. Submersible and air-lift pumps were used to develop the on-Site monitoring wells. However, these pumps were incapable of creating high enough water velocities at the well screen and filter pack to remove all the sediment. As a result, groundwater samples collected from the monitoring wells had varying levels of turbidity (measured as TSS).

As a result of the differences in design, construction, and development of the two types of wells, a production well would be capable of producing turbid-free water from the aquifers on the Site, whereas the monitoring wells are not.

Dissolved Antimony Related to Sample Filtration

Filters used in the collection of filtered groundwater and surface water samples for dissolved metals analyses contributed antimony to the filtered samples. Antimony was detected consistently in filtered groundwater and surface water samples from the Site, but not in unfiltered samples. This is the opposite of the typical situation discussed above, where total metals concentrations are substantially higher than dissolved concentrations due to sample turbidity. There is strong evidence (presented below) that the filters contributed antimony to the filtered water samples, and that antimony is not present at detectable concentrations in Site groundwater or surface water.

First, dissolved antimony was detected in 85 of 168 (51 percent) of the filtered water samples collected during the RI (including groundwater, surface water, field duplicates, and rinsate blanks consisting of deionized water), whereas total antimony was detected in only 2 of 168 (1 percent) of the unfiltered samples. The range of dissolved antimony concentrations was 0.005 to 0.019 mg/L, with an average of 0.008 mg/L (excluding one very turbid sample [7-B-503] from a zone of perched water, for which the dissolved concentration was 0.08 mg/L higher than the total concentration).

Second, a controlled experiment was conducted to evaluate potential antimony contributions from the materials used during water sample filtration. Because a water sample touched three different sampling materials during filtration in the field, each of the materials was tested individually. Samples of deionized water were passed through a length of polyethylene tubing alone and through a length of silicone tubing alone (both tubing materials are used with a peristaltic pump during sample filtration). A sample was then passed through the combined lengths of tubing and the same brand of 0.45-µm filter used for all RI water sampling. In addition, a sample was filtered by the analytical laboratory (ATI) using a different brand of 0.45-µm filter. One sample that did not touch any of the filtration materials was also analyzed as a control. Consistent with the field sampling, the samples touched no other materials (e.g., stainless steel funnel). The five samples were duplicated to verify the results (10 samples total). Of the 10 samples, antimony was detected only in the 2 duplicate samples (0.0078 and 0.018 mg/L) that passed through the type of filter used during the RI work.

Third, independent data from the filter manufacturer indicate that, in a test of one filter, antimony was detected at a low concentration in the initial water passed through the filter, but not after 1 hour of passing water through it. This information suggests that antimony is present at trace concentrations in the filter membrane or housing material and that the antimony is flushed out of the filter with time. Typically in the field, approximately 0.5 liter of water was passed through the filter prior to sample collection. Differences in the volume of water purged through the filter prior to sampling may account for differences in the detected antimony concentrations in the filtered samples. For the controlled experiment, approximately 0.5 liter was also purged prior to sampling; the sample bottles (original and duplicate) were then filled one-half full and then full, alternating between bottles. The differences in duplicate results from the controlled experiment may also indicate decreases in concentrations as more water was passed through the filter.

These combined findings confirm that the detected concentrations of dissolved antimony in the RI water samples are the result of sample filtration and are not representative of Site groundwater and surface water quality. Consequently, the total antimony concentrations are more representative of the Site groundwater and surface water data.

Seep Data

Dissolved copper was the only metal detected, and it was detected in fewer than half of the samples. Ambient surface water data for Puget Sound indicate that these detections are within the range of background concentrations for copper in saline waters like those encountered at the seeps. In addition, elevated copper concentrations were detected in Site soils at only one small location in Area 18; therefore, the Site does not represent a potential source of copper to the seeps.

Summary of Metals Data in Groundwater

With the exception of aluminum, no dissolved metals concentrations in groundwater samples were elevated. Dissolved aluminum was also detected in background groundwater samples and in background soil samples (greater than 10,000 mg/kg [1 percent]), indicating that aluminum is a natural constituent in regional soil and groundwater. Total metals concentrations detected in unfiltered groundwater samples are a result of sample turbidity and therefore are not representative of groundwater quality.

PAH Data for Groundwater

During the RI, 129 groundwater samples were collected and analyzed for PAHs. During the September 1992 sampling round, one of two samples collected from MW-8 contained a total cPAH concentration of 1.56 µg/L. However, this result was not confirmed by the field duplicate sample collected concurrently from MW-8, which had a detected total cPAH concentration of 0.01 µg/L. Concentrations of cPAHs were not detected in groundwater samples or field duplicates from MW-8 in any of the other RI sampling rounds, either before or after the September 1992 round. Furthermore, detected total cPAH concentrations have not exceeded 0.1 µg/L in other groundwater samples collected during the RI. Therefore, based on the available data, the single unconfirmed elevated detection of total cPAH in MW-8 is not considered representative of groundwater quality at this location or elsewhere at the Site.

The only cPAH compound detected in more than 2 percent of groundwater samples collected during the RI was chrysene. Excluding the anomalous September 1992 groundwater sample from MW-8, frequencies of detection for cPAHs in RI groundwater samples are as follows:

- Benzo(a)anthracene: 0/128 (0 percent)
- Benzo(a)pyrene: 0/128 (0 percent)
- Benzo(b)fluoranthene: 2/128 (<2 percent)
- Benzo(k)fluoranthene: 0/128 (0 percent)
- Chrysene: 15/128 (<12 percent)
- Dibenzo(a,h)anthracene: 1/128 (<1 percent)
- Ideno(1,2,3-c,d)pyrene: 0/128 (0 percent)

Because chrysene is the only cPAH compound confirmed in Site groundwater, one-half the detection limit for chrysene was used in calculating total cPAH concentrations for groundwater samples where chrysene was not detected. One-half detection limits were not added for the other cPAH compounds because the data indicate that they were not present in Site groundwater.

Chrysene has been detected inconsistently in groundwater samples from 11 monitoring wells (excluding the September 1992 sample from MW-8) at marginally elevated levels. The chrysene detections occur infrequently in different monitoring wells, including well MW-14 located along the eastern (hydraulically upgradient) edge of the Site. The detected concentrations are very low, ranging from 0.02 to 0.1 µg/L, with an average of 0.03 µg/L relative to the detection limit of 0.01 µg/L. Furthermore, chrysene is not detected consistently at a given well over time (detected in only 1 of the 11 wells in more than 1 of the 4 sampling rounds). Statistical testing (a Fisher's Exact Test) indicates that the proportion of chrysene detections in on-Site monitoring wells (16/129) is not significantly different (at $p = 0.05$; 95 percent confidence level) than the proportion of detections in background wells (0/12).

Benzo(b)fluoranthene and dibenzo(a,h)anthracene were also each detected in one groundwater sample (other than the September 1992 sample from MW-8) at marginally elevated concentrations.

Pre-RI Data

PAHs were detected in some pre-RI groundwater samples collected from newly installed monitoring wells, and the concentrations generally decreased or were not detected in samples from subsequent rounds. These data may indicate potential hydrocarbon contributions from the air rotary drilling method (e.g., compressed air), which was used for installation of pre-RI and RI monitoring wells.

To evaluate potential hydrocarbon contributions during the drilling of the RI monitoring wells, a sample of particulate matter entrained in the compressed air discharging from the air rotary drill bit was collected on a quartz-fiber filter. Air was discharged onto the filter at normal operational pressures for approximately 10 minutes. Following the air discharge, a second filter was set on the drill rig, which was shut off, for 10 minutes to serve as a blank for evaluating ambient conditions. The samples were analyzed for TPH and PAHs to determine constituent mass added to the filter. Because a volume of air was not measured during this test, the sampling results were reported as mass, not a concentration.

TPH was not detected in either sample. One ncPAH (fluoranthene) was measured at 4.41 µg in the sample of discharged air and at 2.64 µg in the blank sample. These data suggest that the air rotary method did not introduce a significant quantity of hydrocarbons to the borehole. However, the pre-RI wells were drilled (4 years earlier) using an older model drill rig, which may not have had as sophisticated an oil-trap system for the compressed air as the rig used and tested during the RI drilling.

Summary of cPAH Data for Groundwater

Although chrysene has been detected inconsistently in RI groundwater samples, no cPAH concentrations were detected at elevated concentrations (excluding one anomalous, unconfirmed sample concentration).

3.2.4 No Active Remedial Action Required for Groundwater

Based on these data, Ecology provided a "No Active Remedial Action" letter (Ecology 1996a) for cleanup in groundwater at the Site indicating that no constituents detected in Site groundwater required active cleanup or any further action except for the long-term monitoring of DNT in selected groundwater wells (Ecology 1996a). The duration of long-term groundwater monitoring for DNT will be specified in the Parcel 1 CAP.

This section presents the findings of the RI surface water and freshwater sediment characterization efforts within the CDB at the Site. The purpose of the surface water and freshwater sediment characterization was to evaluate constituent concentrations in these media. Surface water and sediment sampling and analysis were conducted in the two freshwater bodies on the Site—Old Fort Lake and Sequalitchew Creek. The physical nature of the lake and creek are discussed in Section 3.1.3. Sections 4.1 through 4.4 present specific information on surface water and freshwater sediment sampling and analysis. Appendix C presents supporting tables on surface water and freshwater sediment quality.

4.1 SURFACE WATER AND FRESHWATER SEDIMENT SAMPLING

In December 1986, five surface water/sediment sampling locations were selected for Parcel 1 within the CDB on the Site (Figure 4.1-1). These sampling locations were generally situated to intercept drainage from Site areas identified during the pre-RI work and to provide data regarding potential constituent migration along these pathways. The sampling locations included two locations along Sequalitchew Creek (SW-3 and SW-4) and three locations in Old Fort Lake (SW-5, SW-6, and SW-7). Note that SW-4 represents an upstream creek sampling location because it lies slightly outside the easternmost edge of the CDB. Therefore, SW-4 represents water quality entering the Site but is not influenced by Site activities.

4.1.1 Surface Water

Eleven rounds of surface water sampling were conducted at the Site between December 1986 and December 1992, concurrent with the groundwater sampling rounds. Sequalitchew Creek is intermittent in both its upper and lower reaches, remaining dry during the summer and autumn. As a result, samples from creek sampling location SW-4 could not be collected during all RI sampling rounds. Attempts to sample SW-4 in mid-January 1993 (RI Round 5) were unsuccessful because the creek remained dry at this location. A discussion of surface water sampling procedures is provided in Appendix A.

Consequently, the number of surface water sampling locations and the constituents analyzed for varied over time. The surface water results from the seven pre-RI sampling rounds are summarized in Hart Crowser (1987, 1988a, 1988c, 1988d, 1989a, 1990, and 1991c). Table 4.1-1 summarizes the number of usable data points for surface water (as defined in Section 3.2.1). The combined pre-RI and RI surface water data are discussed in the following subsections.

4.1.2 Freshwater Sediment

Three rounds of freshwater sediment samples have been collected from the Site. The first round of samples was collected in December 1986 as part of the pre-RI site characterization (Hart Crowser 1987). In this pre-RI round, samples were collected from locations SD-3 and SD-4 and SPR-4 in Sequalitchew Creek, and SD-5 and SD-6 in Old Fort Lake as shown in Figure 4.1-1. The freshwater sediment locations were sampled as part of the RI in March 1992, concurrent with RI Round 1 groundwater and surface water sampling. The RI sampling locations were the same as the pre-RI locations, except that SD-7 was added in Old Fort Lake and SPR-4 was not sampled in Sequalitchew Creek. A discussion of freshwater sediment sampling procedures is provided in Appendix A.

As recommended by Ecology, six additional Old Fort Lake sediment sampling locations (SD-501 through SD-506) were established and sampled in August 1993 (Figure 4.1-1). Sampling locations were defined using randomly selected locations within a 100-foot grid system. All locations are at least 50 feet from the July 1993 low water line. Two surface and subsurface composite samples were collected from each of the six locations at 0 to 2 cm and 2 to 15 cm. The 0- to 2-cm sample is representative of recent sedimentation/deposition material, whereas the 2- to 15-cm sample is representative of historical deposition within the assumed predominant biologically active zone (Ecology 1991c). Samples were analyzed for lead and submitted for grain size analysis. Samples were generally of fine-grained soils and organic material. Gravel was not observed at any sampling location.

4.2 SURFACE WATER QUALITY

Detected concentrations of analytes in surface water are discussed in this section. All RI surface water samples were analyzed for nitrate as nitrogen, TPH, 14 metals (total and dissolved), PAHs, NAX, NG, MMAN, TOC, TDS, and TSS. SVOCs were also analyzed in RI Round 1 (March 1992). Surface water quality data tables are provided in Appendix C.

4.2.1 Old Fort Lake Surface Water Quality

During four rounds of RI surface water sampling in Old Fort Lake, NAX, NG, MMAN, TPH, SVOCs, and VOCs were not detected. No concentrations of nitrate detected in Old Fort Lake samples were elevated. Over the full period of sampling in Old Fort Lake (pre-RI and RI), dissolved lead in 2 of 18 samples and dissolved copper in 6 of 12 samples were the only constituents detected at elevated concentrations. As discussed in Section 3.2.3, antimony was contributed to filtered groundwater and surface water samples during sample filtration; as a result, total antimony data are more representative of surface water quality.

Dissolved Lead Data for Old Fort Lake

Two of the 18 samples from Old Fort Lake that were analyzed for dissolved lead had elevated concentrations (0.006 mg/L at SW-6 in June 1988, and 0.004 mg/L at SW-7 in March 1992). Dissolved lead detections have not been confirmed at either sampling location in subsequent sampling rounds (five subsequent rounds at SW-6 and three rounds at SW-7).

Dissolved Copper Data for Old Fort Lake

Five of the 12 samples from Old Fort Lake that were analyzed for dissolved copper had elevated concentrations. The range of detected dissolved copper concentrations from the lake samples was 0.0052 to 0.010 mg/L. Elevated dissolved copper was detected at each of the three lake sampling locations in one or more of the RI sampling rounds.

4.2.2 Sequalitchew Creek Surface Water Quality

During the RI surface water sampling in Sequalitchew Creek, no NAX, NG, MMAN, TPH, SVOCs (other than common laboratory contaminants), or VOCs were detected. No concentrations of nitrate detected in Sequalitchew Creek samples were elevated. Over the full

period of monitoring (pre-RI and RI), concentrations of dissolved lead, dissolved copper, total arsenic, and PAHs were elevated in one or more samples from the creek, as discussed below.

In the December 1986 sampling of Sequalitchew Creek, one or more of the OC pesticide compounds aldrin, endrin, and endrin ketone were detected at estimated concentrations below detection limits in samples from locations SW-3 and SW-4 (Hart Crowser 1987). Because these compounds were also detected in the laboratory preparation blank associated with these samples, the results are not confirmed as being representative of surface water quality. The only sample for which all three of these compounds were reported was from location SW-4, located upstream of the Site. The results of all soil and groundwater sampling conducted during the RI indicate that pesticides are not an indicator constituent at the Site.

Dissolved Lead Data for Sequalitchew Creek

Dissolved lead was detected at a concentration of 0.004 mg/L in one of three samples from background location SW-4. These data suggest that the detected dissolved lead may be related to off-Site sources to the creek, which extends almost 1.5 miles east of the Site. Dissolved lead has been detected at concentrations of 0.001 to 0.004 mg/L in regional rivers and streams (USGS 1987).

Dissolved Copper Data for Sequalitchew Creek

Five of the 11 samples from Sequalitchew Creek that were analyzed for dissolved copper had elevated concentrations. The range of detected dissolved copper concentrations from creek samples was 0.0077 to 0.14 mg/L. The 0.14 mg/L detection (SW-3 in March 1992) is anomalous because it is more than an order of magnitude higher than any other dissolved copper concentration detected in samples from either the creek or the lake, and because total copper was not detected in that sample.

Dissolved copper was also detected in one of the two samples from SW-4 located upstream of the Site, suggesting possible off-Site sources of dissolved copper to the creek. Dissolved copper is commonly detected in regional streams at concentrations of 0.001 to 0.005 mg/L, with reported detections as high as 0.048 mg/L (USGS 1987).

Dissolved lead and copper were occasionally detected in filtered samples at concentrations above corresponding total concentrations in unfiltered samples; these detections were not frequent. These results were not observed in deionized water rinsate blanks. Dissolved concentrations greater than corresponding total concentrations are attributed to sampling or analytical variability rather than contributions from the filter capsules used for sample filtration, as was the case for antimony (refer to Section 3.2.3).

The dissolved copper concentrations detected in Sequalitchew Creek are within the range of the background concentrations detected at the upstream location (SW-4), and within the range of regional background concentrations.

4.2.3 Summary of Surface Water Quality Data

Of the wide range of compounds for which on-Site surface water samples were analyzed, only dissolved lead and dissolved copper were detected at elevated concentrations in one or more

samples from Old Fort Lake and Sequalitchew Creek. Dissolved copper was the only constituent with confirmed elevated detections. Dissolved lead was detected infrequently at marginally elevated concentrations in both Old Fort Lake and Sequalitchew Creek. None of the lead detections were confirmed in preceding or subsequent sampling rounds. In addition, the concentrations of dissolved copper and lead detected in on-Site surface water are within the range of background concentrations detected in an area background (upstream) sampling location in Sequalitchew Creek (SW-4). Concentrations of dissolved copper and lead detected in on-Site surface water are also within the range of background concentrations detected in other regional rivers and streams in Pierce County.

4.3 FRESHWATER SEDIMENT QUALITY

Analytes for the pre-RI sediment samples included antimony, lead, chromium, nitrates, PCBs, and OC pesticides. Analytes for the RI sampling included NAX, MMAN, NG, nitrate plus nitrite as nitrogen, priority pollutant metals (antimony, arsenic, barium, beryllium, cadmium, chromium, copper, lead, mercury, manganese, nickel, selenium, silver, thallium, and zinc) plus aluminum, PCBs, OC pesticides, OP pesticides, PAHs, SVOCs, TPH, and TOC.

NAX, MMAN, NG, PCB, SVOCs, and TPH were not detected. OP pesticide data were rejected due to poor analytical method performance (see Appendix E). No OP pesticides were detected in soil or groundwater samples collected from the Site, and there is no record of historical use of OP pesticides. Freshwater sediment quality data tables are provided in Appendix C.

4.3.1 Old Fort Lake Freshwater Sediment Quality

PAHs, two OC pesticide, and metals were detected in sediment samples collected from Old Fort Lake. Total ncPAHs were detected in samples SD-5 (1.03 mg/kg) and SD-6 (0.60 mg/kg). Total cPAHs were detected in sample SD-5 (0.46 mg/kg).

Two OC pesticides (endosulfan sulfate and 4,4-DDE) were detected at low concentrations in all three sediment samples from Old Fort Lake. Similar to surface water results, these compounds were detected in laboratory blanks, thereby indicating that these detections are not representative of sediment quality.

Old Fort Lake sediment sampling results indicated no elevated concentrations of metals except cadmium and lead. No data were available for aluminum, antimony, beryllium, silver, mercury, and thallium.

Detected concentrations of lead in RI samples ranged from nondetection to 180 mg/kg (SD-5). August 1993 RI sample concentrations in the 0- to 2-cm samples ranged from 69 to 170 mg/kg. Concentrations in the 2- to 15-cm samples ranged from nondetection at 19 to 43 mg/kg. No freshwater sediment lead concentrations were elevated.

4.3.2 Sequalitchew Creek Freshwater Sediment Quality

Two OC pesticides and metals were detected in sediment samples collected from Sequalitchew Creek. Similar to Sequalitchew Creek surface water results, the pre-RI sediment samples from locations SD-3 and SD-4 contained estimated concentrations (below detection limits) of OC pesticides, including gamma-BHC, dieldrin, endrin, 4,4'-DDD, 4,4'-DDE, and 4,4'-DDT (Hart

Crowser 1987). However, like the surface water detections, each of these compounds was also detected in laboratory blanks, thereby indicating that the detections are not representative of sediment quality.

No results from Sequalitchew Creek were elevated for aluminum, antimony, arsenic, cadmium, chromium, copper, lead, mercury, nickel, silver, and zinc. Beryllium, selenium, and thallium were not detected.

4.3.3 Summary of Freshwater Sediment Quality

Of the wide range of constituents for which freshwater sediment samples were analyzed, no constituents were detected at elevated concentrations. There are no published freshwater sediment criteria/standards for Washington State. The freshwater sediment data were compared to standards developed by the State of Wisconsin and the Ontario Province of Canada. These standards were deemed to be the most relevant for the Site. Lead was detected in Old Fort Lake sediments but at relatively low concentrations. Detected concentrations of metals were comparable to available background sediment data for the Puget Sound region.

4.4 NO FURTHER ACTION FOR SURFACE WATER OR FRESHWATER SEDIMENTS

Based on these data, Ecology provided verbal agreement that No Further Action was required for surface water or freshwater sediment at the Site (pending the submittal of a summary of the data), thereby indicating that no constituents detected in Site surface water or freshwater sediment required cleanup or any further action (Ecology 1996d).

Note that although additional groundwater samples (collected at spring locations), surface water and freshwater sediment samples (Sequalitchew Creek), and marine sediment samples (Puget Sound) were collected for characterization purposes, these data are reported in a separate document because the locations from which they were collected are outside the CDB for the Site.

Appendix A
Field Procedures and Logs

The material in Appendix A was developed in draft form by Hart Crowser for the 1994 Draft RI (Hart Crowser 1994d). For completeness, it is retained here as it was developed. It includes references to all sampling conducted as specified in the RI/FS Management Plan (Hart Crowser 1992a). As a result, it refers to locations sampled outside the Consent Decree Boundary that will be the subject of additional reports.

Appendix B presents soil quality data representing current Site conditions as of September 2001. The tables are organized and labeled according to area as discussed in Section 2. The tables are in the same order as that in which they are discussed in Section 2—Site Areas (by number), AP Areas, Site Reference Area (REF), and Narrow-Gauge Railroad (NGRR). Refer to Section 2 for a complete description of each Site Area. Specific notes for the tables are as follows:

1. Blanks indicate no analysis for a specific constituent.
2. Soil quality data representing Site conditions as of September 2001 are provided in the tables, including pre-RI, RI, and interim source removal verification sampling results.
3. Data qualifiers include the following:

   U Not detected at associated detection limit
   J Estimated concentration
   UJ Not detected; associated detection limit is an estimate
   R Rejected data, as determined during data validation
   S Sum of individual constituent concentrations (e.g., total cPAHs and total PCBs)
   X Elution pattern does not match typical product

4. Field duplicate samples are designated with sample ID suffixes of D, DUP, or SSE (the different suffixes have identical meanings).
5. As discussed in Section 2 of the report, soil quality data from the following areas have been redesignated as follows:

   - Areas AP-A and AP-G have been included in the Areas of Potential Concern tables.
   - Areas AP-B and AP-D have been included in Area 26.
   - Samples designated AP-H at the time of sampling have been divided into Areas 25 and 26.
   - Sampling locations within 25 feet of a narrow-gauge railroad grade have been included in the Narrow-Gauge Railroad designation.

The redesignated soil quality data have been included in soil quality data tables in this appendix for the appropriate areas as listed above.

The tables were developed on the basis of information provided to URS in an analytical database submitted in final form for this RI on April 1, 2002 (Pioneer 2002).

Appendix C
Groundwater, Surface Water, and Freshwater Sediment Quality Data

Appendix C provides groundwater, surface water, and freshwater sediment quality data for the Site. Specific notes for the tables are as follows:

1. Blanks indicate no analysis for a specific constituent.
2. Data qualifiers include the following:

U	Not detected at associated detection limit
J	Estimated concentration
UJ	Not detected; associated detection limit is an estimate
R	Rejected data, as determined during data validation
S	Sum of individual constituent concentrations (e.g., total cPAH and total PCBs)

3. Surface water sample ID suffixes include the month and year of sample collection (e.g., -3-88 sample ID suffix indicates sample collection in March 1988).
4. Field duplicate samples are designated with sample ID suffixes of D or DUP (these suffixes have identical meanings).

Groundwater Quality Data

Surface Water and Freshwater Sediment Quality Data

The following appendix material was developed in draft form by Hart Crowser for the 1994 Draft RI (Hart Crowser 1994d). For completeness, it is retained here as it was developed. It includes references to all sampling conducted as specified in the RI/FS Management Plan (Hart Crowser 1992a). As a result, it refers to locations sampled outside the Consent Decree Boundary that will be the subject of additional reports.

Appendix D
Laboratory Physical Soils Testing

This appendix material was developed in draft form by Hart Crowser for the 1994 Draft RI (Hart Crowser 1994d). For completeness, it is retained here as it was developed. It includes references to all sampling conducted as specified in the RI/FS Management Plan (Hart Crowser 1992a). As a result, it refers to locations sampled outside the Consent Decree Boundary that will be the subject of additional reports.

The Hart Crowser soils laboratory conducted mechanical (sieve) and hydrometer analyses to provide grain size distributions for aquifer and aquitard materials, respectively. In addition, flexible-wall permeability tests were conducted to estimate vertical hydraulic conductivity of the aquitard material.

Mechanical Analyses. The Hart Crowser soils laboratory conducted mechanical grain size analyses using standard sieve sizes in accordance with ASTM D 422. The wet sieve analyses were performed to determine the size distribution greater than the No. 200 mesh sieve. Figure 1 presents the classification system used for the grain size analyses. The results of the tests are presented as curves in Figures 2 through 12, plotting percent finer against grain size.

Hydrometer Analyses. Samples of the Kitsap Aquitard material were analyzed using the hydrometer method, or a combined analysis (mechanical plus hydrometer), to determine the size distribution smaller than the No. 200 mesh sieve (i.e., determine percent silt and percent clay). The hydrometer testing was conducted in accordance with ASTM D 422. The results of the tests are presented as curves in Figures 2 and 4.

Laboratory Vertical Hydraulic Conductivity Testing. Testing of vertical hydraulic conductivity was conducted on two undisturbed samples of the Kitsap Aquitard material.

The tests were performed in a triaxial cell using "flexible wall" permeameter techniques, which allowed application of confining stresses approximately equal to the in situ effective overburden stresses. The sample was oriented in its stratigraphically correct position (up versus down) and flow was directed vertically downward through the sample using falling head techniques. The tests were run until steady state conditions were established. The results of the vertical hydraulic conductivity testing are presented in Table 1.

Table 1
Summary of Laboratory Vertical Hydraulic
Conductivity (K) Results for Kitsap Aquitard Samples

Sample No.	Sample Description	Estimated Vertical K in cm/sec
MW-20, S-24E	Slightly clayey, sandy SILT	8×10^{-7}
MW-23, S-25A	Very sandy SILT with trace peat and sand partings	1×10^{-7}
	Geometric Mean:	3×10^{-7} cm/sec

Appendix E
Data Quality Assessments

Recent Data Quality Assessment

Pre-1994 Data Quality Assessment

This appendix material was developed in draft form by Hart Crowser for the 1994 Draft RI (Hart Crowser 1994d). For completeness, it is retained here as it was developed. It includes references to all sampling conducted as specified in the RI/FS Management Plan (Hart Crowser 1992a). As a result, it refers to locations sampled outside the Consent Decree Boundary that will be the subject of additional reports.

Appendix A
Field Procedures and Logs

The material in Appendix A was developed in draft form by Hart Crowser for the 1994 Draft RI (Hart Crowser 1994d). For completeness, it is retained here as it was developed. It includes references to all sampling conducted as specified in the RI/FS Management Plan (Hart Crowser 1992a). As a result, it refers to locations sampled outside the Consent Decree Boundary that will be the subject of additional reports.

APPENDIX A: FIELD PROCEDURES

The Remedial Investigation (RI) field program was initiated in February 1992. The initial phase of soil sampling was conducted between February and May 1992. Following Washington State Department of Ecology (Ecology) review of the initial soil quality results from the kettle Areas 7, 16, and 26 as presented in Hart Crowser (1992d), additional soil sampling was conducted in the three kettle areas and selected other areas in late June and July 1992. Supplementary soil sampling was conducted in selected areas of the Site between October 1992 and January 1994. Quarterly groundwater sampling for the RI has been conducted from March 1992 through April 1994 (Table 3.2-1 in Volume 1 summarizes all pre-RI and RI groundwater sampling conducted to date).

Soil Quality Explorations

The RI soil sampling program included completion of the following explorations:

- 328 test pits;
- 15 observational test pits (from which samples were generally not collected);
- 40 trenching locations around foundations;
- 30 soil borings;
- 41 hand-augered borings; and
- 1,676 surface samples.

In addition, 10 samples of railroad ties (wood) were collected. The number of explorations indicated above does not include additional samples collected during the pre-RI and interim source removal.

The results of the RI subsurface exploration program are presented on the exploration logs, which are grouped by Site RI Area, within this appendix. Surface soil sampling forms are not presented in this appendix. The exploration logs represent our interpretation of data compiled from drilling and excavation, sampling, and field testing information at the time of the exploration (exploration dates are listed on each log). Because these logs describe conditions encountered at the time of exploration, soil sample depths and ground surface elevations on all exploration logs are referenced to the grade at the time of exploration, and have not been adjusted for regrading or removal resulting from interim source removal, as was done in the body of this report. Although interim source removal has removed most of the Area 5 explorations completed during the RI, the exploration logs are included in this appendix. Those samples removed during subsequent interim source removal (and thus not representative of current Site conditions) are denoted with (R) next to the sample number on the exploration logs. Field procedures for each of the exploration types are discussed in more detail below.

Test Pit Excavations

Test pits were excavated using a four-wheel-drive Case 580K backhoe, which was capable of operating to depths of approximately 10 to 12 feet. To minimize the sloughing of the test pit

side walls, the backhoe was generally used to dig as deep as required to collect the shallowest proposed sample. Once the sample had been collected, the pit was deepened to the bottom of the next proposed sampling depth. The soil samples were composited from the determined sample depth interval (e.g., 3 to 6 feet), and generally from the two long walls of the excavation (i.e., parallel to the direction of the scoop), except in cases where a discrete portion of the excavation was sampled based on field observations (e.g., stained soils).

If signs of subsurface alteration (e.g., unnatural staining, deteriorated gravels) were still evident at a depth of 10 feet, every effort was made to excavate and sample deeper. However, sloughing gravelly soils generally prevented excavation beyond a depth of approximately 10 feet. The sample intervals specified in the area-specific soil sampling and analysis plans (RI/FS Management Plan; Hart Crowser, 1992a) were followed to the extent possible; however, sample collection intervals were based on field conditions and best professional judgement.

Soil samples from the test pits were collected either by removing depth-specific sample material from the center of the backhoe bucket with a stainless steel spoon, or by using a stainless steel spoon with 10-foot-long extending handle to sample the test pit walls. Soil samples were mixed in a stainless steel bowl, at which time gravels larger than approximately 1/2 inch in diameter were removed since they would not be analyzed by standard laboratory methods. The samples were placed in laboratory-supplied clean glass jar(s) with teflon-lined screw caps, and immediately placed in a cooled ice chest. Soil samples collected for field headspace vapor measurements and volatile organic analyses were placed directly into appropriate sampling jars without mixing. Prior to placement in the ice chest, all sampling jars collected for nitroaromatic explosive (NAX) analysis were wrapped in aluminum foil to limit photolysis (light-induced breakdown) of the nitroaromatic compounds. Samples selected based on the RI/FS Sampling and Analysis Plan (Section 4 in Hart Crowser, 1992a) and field observations were delivered to the analytical laboratory (ATI-Renton or Hart Crowser Chemistry Laboratory) for chemical analyses. Remaining samples were stored under refrigeration at the Site.

The backhoe bucket was steam cleaned after each test pit excavation. All steam cleaning water was collected in a galvanized trough and pumped into 55-gallon drums. Sampling equipment was decontaminated between collection of each soil sample as discussed in the ***Equipment Decontamination*** section.

Soils and other materials encountered in the test pits were documented on a field test pit log form (Figure 5-4 in Hart Crowser, 1992a). Test pits were photographed to show the excavation in relation to its immediate surroundings. Once sampling was completed and the test pit logged and photographed, the test pit excavations were backfilled with the excavated soil and compacted using the backhoe. The test pit locations were staked for subsequent survey.

Observational test pits were also completed in some locations for the purpose of observing subsurface conditions. Dimensions of these excavations varied depending on the conditions to be observed. Soil samples were collected from some observational test pits based on

conditions encountered. All excavation and sampling protocols were generally consistent with those described above for typical test pits.

In addition, trenches approximately 4 feet deep were excavated around the perimeters of selected foundations in Area 18 to observe the presence of potential buried pipes or other drainage systems. Discrete soil samples were collected from depths of 0 to 1 foot and 3 to 4 feet at locations based on field observation. All excavation and sampling protocols were generally consistent with those described above for typical test pits.

Soil Borings

A hollow-stem auger was used to drill soil borings completed for soil quality sampling during the RI. The borings were advanced using either a Mobile B-61 or a Jefco SD-300 drill rig, using 4-inch inside diameter hollow-stem auger. The Jefco rig was used for completion of the deep Phase II RI borings in the kettles, since it has the capability of switching from hollow-stem auger to air rotary operation if refusal was encountered with auger operation at depth. However, all soil borings for soil sample collection (chemical analyses) were completed using hollow-stem auger operation, even to a depth of 100 feet in 26-B-503 completed in the bottom of the Area 26 kettle.

Standard hollow-stem auger drilling techniques were used in advancing the soil borings. No grease other than vegetable oil was used on the auger section joints or accessory tooling. No water was added to the boreholes. Soil borings were photographed to show the exploration in relation to its immediate surroundings and staked for surveying.

Soil Sampling in the Borings. During hollow-stem auger drilling, soil samples were typically collected at 2.5-foot-depth intervals or continuously, beginning at a depth of 2.5 feet below ground surface. Surficial samples were collected manually from the upper 6 inches of material at each boring location following the removal of vegetation or forest duff, if present. Continuous sampling was often required to collect adequate soil sample volume as a result of poor sample recovery caused by the gravelly soils.

Soil samples obtained during hollow-stem auger drilling were collected using the Standard Penetration Test (SPT) procedure described in ASTM D 1587 modified to include a 3-inch-diameter split-spoon and a 300-pound hammer. The procedure involves driving a standard 3-inch outside diameter split-spoon sampler into the soil a distance of 18 inches beyond the end of the borehole. The sampler is driven by a 300-pound hammer dropping 30 inches onto the end of the drilling rod. The number of blows required to drive the sampler the final 12 inches is the (modified) Penetration Resistance. This resistance provides a measure of the density of granular soils (sands and gravels) and consistency of finer grained cohesive soils (silts and clays). This information, along with soil descriptions and other observations, was recorded on field boring forms (Figure 5-4 in Hart Crowser, 1992a).

Samples to be retained for chemical analysis were placed in laboratory-supplied clean glass jar(s) with teflon-lined screw caps, and immediately placed in a cooled ice chest. Where poor recovery occurred, soil was placed in a clean stainless steel bowl covered with aluminum foil

and composited with the next sample interval (typically immediately below). Gravels larger than approximately 1/2 inch in diameter were removed from the samples since they would not be analyzed by standard laboratory methods. Soil samples collected for field headspace vapor measurements and volatile organic analyses were placed directly into appropriate sampling jars without mixing. Prior to placement in the ice chest, all sampling jars collected for nitroaromatic explosive (NAX) analysis were wrapped in aluminum foil to limit photolysis (light-induced breakdown) of the nitroaromatic compounds. Selected samples based on field observations and soil recovery were delivered to ATI-Renton for chemical analysis. Remaining samples were stored under refrigeration at the Site.

The auger flights and all downhole sampling equipment was steam cleaned after completion of each boring. The split-spoon sampler and all other sampling equipment (e.g., stainless steel spoons or bowls) were decontaminated after each sample using the procedures discussed in the ***Equipment Decontamination*** section.

Hand-Augered Borings

Hand-augered borings were completed throughout the Site where backhoe and drill rig access was limited. Depending on soil conditions, a combination of stainless steel hand-auger, shovel, or post hole digger were used to excavate soils to a depth of three feet.

All samples were collected as the boring was advanced, either from the hand-auger or from the side walls of the (shovel) excavations. Samples were composited in a stainless steel bowl and placed in laboratory-supplied clean glass jar(s) with teflon-lined screw caps, and immediately placed in a cooled ice chest. Gravels larger than approximately 1/2 inch in diameter were removed from the samples since they would not be analyzed by standard laboratory methods. Prior to placement in the ice chest, all sampling jars collected for NAX analysis were wrapped in aluminum foil to limit photolysis (light-induced breakdown) of the nitroaromatic compounds. Soil samples collected for field headspace vapor measurements and volatile organic analyses were placed directly into appropriate sampling jars without mixing.

The hand-augered boring data were recorded on field test pit logs (Figure 5-3 in Hart Crowser, 1992a). Selected samples based on field observations and soil recovery were delivered to the analytical laboratory for chemical analysis. Remaining samples were stored under refrigeration at the Site. All equipment was thoroughly decontaminated between sample locations as discussed in the ***Equipment Decontamination*** section. Hand-augered borings were photographed to show the exploration in relation to its immediate surroundings, and staked for surveying.

Surface Soil Samples

Surface samples were collected from the upper six inches of soil following the removal of vegetation or forest duff, if present. Each sample was collected using a decontaminated shovel and/or stainless steel spoon. The soil was placed in a decontaminated stainless steel bowl. Gravels larger than approximately 1/2 inch in diameter were removed from the

samples since they would not be analyzed by standard laboratory methods. The samples were placed in laboratory-supplied clean glass jar(s) with teflon-lined screw caps, and immediately placed in a cooled ice chest. Prior to placement in the ice chest, all sampling jars collected for explosive analysis were wrapped in aluminum foil to limit photolysis (light-induced breakdown) of the explosive compounds. No surface samples were analyzed for volatile organics or field screened using the HNU photoionization detector (PID).

All surface sample soil descriptions and observations were recorded on Surface Sample Collection forms (Figure 5-5 in Hart Crowser, 1992a). After completion of sampling, each location was staked or flagged for subsequent survey. Surface samples collected on a grid across the Site Reference Area were generally surveyed prior to sample collection. All equipment was thoroughly decontaminated between sample locations as discussed in the ***Equipment Decontamination*** section.

Headspace Vapor Measurements

In areas where volatile organic analyses of soils were performed, a portion of the soil was collected for soil vapor headspace measurements to screen for the presence of volatile organic compounds (VOCs).

For soil samples to be screened for VOCs, a portion of the sample was retained in a clean glass jar, leaving an air "headspace" above the soil. The mouth of the sampling jar was covered with aluminum foil prior to capping with the plastic cover. The aluminum foil helped limit escape of volatile compounds as the measurement was taken. The soil samples were screened using an HNU PID, Model PID 101, with a 10.2 eV lamp. The headspace measurements were recorded on appropriate field logs.

Railroad Tie Sampling

Wood samples were collected from remaining railroad ties along various stretches of historical railways throughout the Site. The wood samples were collected using an electric drill and 5/8-inch ship-type auger drill bit. Samples consisted of wood cuttings generated during drilling through the thickness of the tie. The wood cuttings were mixed in a stainless steel bowl prior to placement in a laboratory-supplied glass jar with teflon-lined cap.

Hydrogeologic Explorations

The RI hydrogeologic field exploration program included installation of the following:

- Seven monitoring wells (MW-20 through MW-26) in the Water Table Aquifer;
- One monitoring well (MW-27) in a zone of perched groundwater above the Water Table Aquifer;
- Three monitoring wells completed to intercept perched water, if present, beneath the three major geologic kettles (7-B-503 in Area 7, 16-B-501 in Area 16, and 26-B-503 in Area

26);

- Four wellpoints at spring locations (SPR-2 through SPR-5) for groundwater sampling or water level measurements; and

- Six staff gages for measuring surface water elevation (SG-1 through SG-5 in Sequalitchew Creek, and SG-6 in Old Fort Lake).

Monitoring Well Drilling

Two methods of drilling, hollow-stem auger and air rotary, were used for drilling and installation of monitoring wells during the RI. Procedural details of drilling and soil sampling are discussed below.

Hollow-Stem Auger Drilling Methods. Hollow-stem auger was used to drill and complete monitoring wells MW-24, MW-25, and MW-26, as well as the three monitoring wells completed to monitor perched water in each of the three kettle areas (7-B-503, 16-B-501, and 26-B-503). Standard hollow-stem auger drilling techniques were used to advance the soil borings. No grease other than vegetable oil was used on the auger section joints or accessory tooling. No water was added to the boreholes.

In general, soil samples were collected at 5-foot-depth intervals to the depth of exploration indicated on the exploration logs (Figures A-MW-1 through A-MW-8). Samples were collected more frequently when changes in soil type were noted or when sample recovery was poor. The soil samples were collected using the Standard Penetration Test (SPT) procedure described in ASTM D 1587, modified to include a 3-inch-diameter split-spoon and a 300-pound hammer. The sampling procedures were similar to those discussed above for soil quality sampling from borings, except that samples from the monitoring well borings were retained in plastic jars since they were not submitted for chemical analysis. Samples collected from the monitoring well borings were retained only for physical testing (e.g., grain size or laboratory permeability testing), and to allow more detailed observation of geologic material types (e.g., between borings).

Air Rotary Drilling Methods. The air rotary method was used to drill and install five monitoring wells (MW-20 through MW-23 and MW-27). Borings were advanced with a TH-60 top-drive air rotary drill rig using an air-driven percussion bit inside 6- and 9-inch-diameter driven casings. Standard air rotary drilling techniques were used. In general, these techniques involve drilling ahead of the temporary driven casing a distance of one to three feet, driving the casing the same distance by means of a rig-mounted air hammer, and returning the drill cuttings to the surface with pressurized air exiting from the drill bit. An in-line oil trap was used on the air compressor discharge line to restrict oils or greases potentially present in the pressurized air from entering the borehole. A sample of particulate matter entrained in the compressed air was collected to evaluate potential contributions of hydrocarbons to the boreholes. This sampling indicated negligible amounts of hydrocarbon were added to the borehole during drilling (refer to Section 3.2.3 in Volume 1).

In drilling the first monitoring well boring, a thin zone of saturation was observed perched on a till unit. Monitoring well MW-27 was completed in this perched water unit, which is present only seasonally. As a result, the drilling method for the remaining borings was altered to include dual casings, such that the perched unit was sealed off prior to drilling through it to the underlying aquifer (in accordance with Chapter 173-160 WAC). In drilling with the dual casings, the borings were advanced to a depth of approximately 50 feet using 9-inch-diameter threaded casing. Once the 9-inch casing was set into the low-permeability till unit, the 6-inch-diameter threaded casing was telescoped down within the outer casing and was advanced through the till to the depth of exploration. As it turned out, the till and perched water were observed only at the MW-27 location (well MW-22 was advanced with the dual casings through the till to the Water Table Aquifer). Regardless, the dual casing method was used in the other air rotary boreholes as a precaution.

In monitoring wells MW- 20 and MW-21, collapsing borehole (heaving) conditions were encountered in fine sand and it was necessary to add water to the borehole to control heave and advance the borehole. The majority of this added water was removed during normal air rotary drilling operations. Regardless, the volume of water added to each boring was recorded on the field log and subsequently removed during well development.

In general, soil samples were collected from the air rotary borings at 5-foot-depth intervals to depths of 100 feet and 10-foot-depth intervals below a depth of 100 feet. Samples were collected more frequently when changes in soil type or conditions were noted in cuttings. Air rotary samples were collected using the Standard Penetration Test (SPT) procedure described in ASTM D 1587 modified to include a 3-inch-diameter split-spoon and a 300-pound hammer. Air rotary samples were used only for descriptive and or physical testing purposes, and were retained in plastic jars.

In accordance with the RI/FS Management Plan (Hart Crowser, 1992a) drill cuttings from monitoring well borings were retained on visqueen-covered, visqueen-lined bermed piles or shallow pits next to the wellheads.

Samples of Kitsap Aquitard Material. Two undisturbed samples of the Kitsap Aquitard were collected during air rotary drilling of the monitoring wells. The samples were collected using a 3-inch outside diameter split-spoon with brass ring inserts. Three 6-inch brass rings were inserted in the sampler, which was lowered down the borehole and driven with a 300-pound hammer. The undisturbed samples collected from MW-20 and MW-23 were submitted for vertical hydraulic conductivity tests using flexible wall permeameter methods at Hart Crowser's geotechnical laboratory. Following extraction from the split-spoon, the samples were capped and sealed with electrical tape and placed in sealable plastic bags with moist paper towels to avoid desiccation.

The first attempt to collect an undisturbed sample of the aquitard material (from MW-22) using a shelby tube was unsuccessful because after the shelby tube was driven into the very stiff silt (too stiff for the tube to be pushed), the pins attaching it to the drill rods snapped during the retrieval attempt. The shelby tube remained in the bottom of the boring preventing further sampling efforts. No cohesive soils suitable for laboratory hydraulic conductivity (K)

testing were encountered during the drilling of MW-21.

Monitoring Well and Wellpoint Installation

Monitoring Well Installation. Groundwater monitoring wells were installed in general accordance with Chapter 173-160 WAC "Minimum Standards for Construction and Maintenance of Wells". The monitoring well construction diagrams for the newly installed wells are presented on Figures A-MW-1 through A-MW-8 at the end of this appendix. The well installation procedures were essentially the same for all monitoring wells, regardless of the drilling method (hollow-stem auger or air rotary), and are discussed below.

The well installation procedure began by pulling back the auger or temporary steel casing to the desired depth. If the well completion depth was above the bottom of the boring, the lower portion of the borehole was backfilled with bentonite. As well installation proceeds, the auger or casing was incrementally withdrawn.

A threaded end cap was attached to the bottom of the 10-foot or 15-foot length of 2-inch-diameter Schedule 40 PVC 0.020-inch slotted well screen. For each well, the well screen was threaded to the PVC riser pipe and lowered into the casing. No glues or solvents were used to couple the PVC casing. In an attempt to keep the PVC straight in the deep monitoring wells, the PVC was generally suspended from a drill rig line throughout installation.

Silica sand (Colorado 10/20) was used as a filter pack around the well screen, and typically extended to a level three to five feet above the top of the screen. Bentonite chips were placed as an annular seal above the sand pack. The annular seal extended up to a depth of approximately 2 to 5 feet below ground. All new wells were completed with concrete surface seals and locking above-ground protective steel monuments. The PVC well cap was vented and marked with the well number.

Installation of Wellpoints for Springs 2, 3, 4, and 5. Four wellpoints were installed for the purpose of monitoring groundwater quality and/or water levels at spring locations along Sequalitchew Creek.

The wellpoints were installed at Springs 2, 4, and 5 using a 12-pound sledge hammer to drive the point to a depth of approximately 3 to 4 feet below ground. The wellpoint at Spring 3 was driven horizontally 2.5 feet into the creek bank directly above a compressed peat layer (Kitsap Aquitard), over which the spring discharge occurs. The 3-foot-long wellpoint screen sections consisted of 1.25-inch inside diameter, PVC-lined, galvanized steel with crescent-shaped openings covered by 0.010-inch mesh screen. All well points were subsequently surveyed for location coordinates and elevations.

Monitoring Well Development

The newly installed monitoring wells were developed using either a Grundfos Ready Flow II submersible pump and/or a Geoguard gas drive pump. The Geoguard pump was driven by an

air compressor fitted with an in-line oil trap.

Monitoring wells MW-20 through MW-24 and MW-27 were initially developed using the submersible pump. During development of these wells, the pump frequently shut down due to accumulations of fine-grained sediment inside of the pump housing, necessitating that the pump be pulled and cleaned several times per well. After each cleaning, the performance of the pump gradually deteriorated as the pump became clogged with silt.

Following the first round of groundwater sampling in March 1992, additional well development was performed in each of the newly installed monitoring wells using the Geoguard gas drive (air-lift) pump in an effort to redevelop the well and decrease the turbidity of the groundwater samples. Because the air lift system was less impeded by suspended sediment in the water, the second round of well development was more successful than the initial effort using the submersible pump. The two Area 40 wells installed in July 1992 (MW-25 and MW-26) were developed using the air lift pump alone.

All downhole development equipment was decontaminated before use and between wells. The decontamination consisted of scrubbing with Alconox solution, followed by a tap water rinse and a thorough spray with deionized water. In addition, the submersible pump was run submersed in an Alconox solution followed by tap water. Following development, each newly installed well was fitted with a new dedicated PVC bailer and new polyethylene rope kept within a plastic bag in the well monument.

All development water from the new monitoring wells was barreled and subsequently transferred to on-site Baker tanks (under the direction of DuPont Environmental Remediation Services [DERS]) for subsequent disposal.

Field Exploration Documentation

A record of drilling and soil sampling operations was maintained on a field exploration log form. Soil samples recovered during drilling were visually classified in the field in general accordance with the system presented on Figure A-1, Key to Exploration Logs. The soil descriptions included the following properties: density of sands and gravel/consistency of silts and clays, moisture, color, minor constituents, and major constituents. The presence of non-soil substances (e.g., debris or wood) was also noted.

Other pertinent data recorded on the field exploration logs included:

- Soil sample interval, type, and recovery;
- Drilling conditions;
- Depth at which groundwater was encountered in boring;
- Soil vapor headspace (PID) readings, if applicable; and

- Soil pH measurements, if applicable, using pH paper in a soil/deionized water slurry.

The logs for monitoring wells, test pits, soil borings, and hand-augered borings completed during the RI are provided at the end of this appendix. Following the RI monitoring wells, all the soil quality exploration logs are arranged according to area (e.g., Area 6, Area 7, etc.). The figure numbers for these logs include the area number (e.g., Figure A-6-1 for Area 6, etc.).

Equipment Decontamination

Before drilling began, the drill rig, auger sections, steel casing sections, and downhole equipment were steam cleaned. Between each boring, the drilling and downhole soil sampling equipment was steam cleaned using tap water from the on-site fire protection system. All steam cleaning water was collected in a galvanized trough and pumped into 55-gallon drums. At the completion of drilling activities all decontamination water was collected and pumped into on-site Baker Tanks (under the direction of DERS) for subsequent disposal.

Between collection of each soil sample for chemical analysis, all soil sampling equipment was decontaminated using the following procedures:

- Scrub with detergent solution (ALCONOX);
- Rinse with tap water; and
- Thoroughly spray with deionized water.

Borehole Abandonment

Boreholes, which were not completed as monitoring wells, were abandoned by pouring bentonite chips down the auger as the auger was withdrawn, in accordance with Chapter 173-160 WAC. The borings were capped with concrete surface plugs and staked for subsequent surveying.

Exploration Survey (Horizontal and Vertical Control)

Horizontal and vertical surveying control was provided for the newly installed monitoring wells. The surveying was completed by ESM, Inc. of Renton, Washington. The top of the PVC well casings were surveyed to a vertical accuracy of 0.01 foot, relative to National Geodetic Vertical Datum (NGVD). The surveyed measuring point was identified on the well casings for reference during depth to water measurements. Horizontal positions of the well casings were electronically surveyed to an accuracy of 0.1 foot, relative to state plane coordinates.

The horizontal and vertical positions of all soil quality explorations, wellpoints, springs, sea level seeps, surface water sampling locations, and staff gages were surveyed by Hart Crowser

using a Pentax PTS-II Series Electronic Total Station Laser Transit. The transit was calibrated at each location using panel marks and survey points established by ESM, Inc., or surveyed monitoring well top of casings.

Soil sampling locations except for selected locations within the Site Reference Area and the area background samples were surveyed by Hart Crowser using the Total Station Laser Transit. At each location, the State Plane coordinates (northing and easting) were recorded. Ground surface elevations were also generally recorded. The grid coordinates for the initial Site Reference Area samples were located on detailed 1 inch = 100 feet base maps (developed from the aerial flyover), and then field located according to these maps using conventional tape and compass techniques and landmarks as guides. Sample locations for Site Reference Area sampling conducted in November 1993 through January 1994 were surveyed prior to sampling based on predetermined grid coordinates. The (off-site) area background samples were measured from landmarks (e.g., dirt roads) using tape and compass techniques.

Groundwater and Surface Water Sampling

The first four rounds of RI groundwater and surface water sampling were conducted at all locations which could be sampled in March, June, September, and December of 1992. A fifth round of sampling was conducted at selected locations in January 1993. Quarterly groundwater sampling at selected locations has subsequently been conducted in April, July, and October 1993, and January and April 1994. Additional discussions of groundwater sampling and surface water sampling conducted to date are provided in Sections 3.2.1 and 4.2.1 of Volume 1, respectively. The following sections discuss the equipment and procedures used for groundwater and surface water sampling.

Groundwater Sampling Equipment

The following equipment was used for groundwater and surface water sampling:

- pH, temperature, and electrical conductivity meters;
- Oxygen meter;
- Electronic well sounder;
- Dedicated polyethylene rope;
- Dedicated PVC bailer;
- Stainless steel funnel;
- Stainless steel bucket;
- 0.45 micron filter and peristaltic pump with silicone and polyethylene tubing;
- Laboratory-supplied sampling containers with appropriate preservatives already added;
- Blue Ice and cooler; and
- Sample Custody Record.

Monitoring Well and Wellpoint Sampling Procedures

Groundwater samples were collected from monitoring wells and wellpoints (at springs) using

the following procedures:

- The water levels in each well were measured and the volume of water within the well casing calculated.

- The sampling site was prepared by laying out visqueen around the base of each monitoring well. The Groundwater Sampling Data Form (Figure 5-7 in Hart Crowser, 1992a) was filled out;

- Three casing volumes of water were purged from the well using a dedicated PVC bailer and rope. A 1-inch-diameter stainless steel bailer was used for the wellpoints (not dedicated). All purge water was barreled. During purging, field parameters (pH, temperature, and specific conductance) were measured following removal of one, two, and three casing volumes. If the pH and conductance measurements were approximately stable between the second and third casing volumes, the dissolved oxygen and temperature were measured and the groundwater sample was collected. If the parameters were not considered stable, purging continued with parameter measurements after each additional half casing volume. All readings were recorded on the Groundwater Sampling Form. Because Spring-3 flowed continually (from the horizontal wellpoint), it was sampled without purging;

- Once purging was completed, the groundwater sample was collected using the dedicated PVC bailer in the monitoring wells, or 1-inch-diameter stainless steel bailer in the wellpoints, and poured through a decontaminated stainless steel funnel into clean, labeled bottles provided by the laboratory;

- For samples collected for priority pollutants, bottles for volatile organics (VOC) analysis were filled first. The VOC sample bottles were slowly filled with water, capped, inverted, and tapped to check for remaining air bubbles. Samples for dissolved metals analysis were filtered directly from the bailer using a peristaltic pump with in-line 0.45 micron filter;

- Once filled, each bottle was capped and placed into coolers with Blue Ice. VOC bottles were placed in plastic sealable bags to minimize possible cross contamination and/or breaking of the bottles. These bottles were also kept away from direct contact with the Blue Ice to prevent freezing of the sample water;

- At the end of each sampling day, the samples were hand delivered to ATI-Renton using standard chain of custody procedures.

Background Groundwater Quality Sampling Procedures

Groundwater samples were also collected twice (July and December 1992) from six off-site wells to evaluate area background groundwater quality. These six wells included four production wells and two monitoring wells. Locations of the background wells are discussed in Section 3.2 of Volume 1.

Samples from the production wells were collected from sampling spigots positioned in-line prior to any treatment systems. Prior to sample collection the pump was run for sufficient time to purge three casing volumes. Samples from these spigots were poured directly into the sample bottles through decontaminated stainless steel funnels. Samples for dissolved metals were filtered from water collected in a decontaminated stainless steel bucket using the same procedures as for on-site monitoring wells. Samples from the monitoring wells were collected from dedicated Hydrostar sampling pumps in the wells. These pumps were driven by an air compressor. The sampling procedures were the same as for the production wells.

Surface Water and Sea Level Seep Sampling Procedures

Surface water samples were collected using a decontaminated stainless steel bucket dipped into the lake or creek. For sampling of Sequalitchew Creek, the samples were collected beginning at the furthest downstream location (SW-1) and moving upstream. For the Sea Level seeps on the beach, the bucket was positioned to intercept the seepage. Because the seeps are submerged at high tides, the Sea Level seeps were sampled at low tide.

Field parameters and dissolved oxygen content were recorded prior to sample collection. Sample bottles were filled through a stainless steel funnel into the sample bottles. Samples for dissolved metals analysis were filtered directly from the bucket using a peristaltic pump with in-line 0.45 micron filter.

As with all water samples collected during the RI, each bottle was capped and placed into coolers with Blue Ice. At the end of each sampling day, the samples were hand-delivered to ATI-Renton using standard chain of custody procedures.

Freshwater Sediment Sampling Procedures

Freshwater sediment samples were collected from each of the 7 surface water sampling locations concurrent with the first round of RI surface water sampling in March 1992. At each sampling location, the surface water sample was collected prior to collection of the sediment sample to avoid creating excessive turbidity (non-representative) in the water sample.

Freshwater sediment samples collected in March 1992 were grab samples collected from the upper 6 inches of sediment substrate using a decontaminated shovel. The sediment sample was mixed in a stainless steel bowl using a stainless steel spoon prior to placing the sample in sample jars. Gravels larger than approximately 1/2 inch in diameter were removed since they would not be analyzed by standard laboratory methods. At two locations in the creek and one location in the lake, an additional portion of sample was retained for grain size analysis (Appendix E).

In July 1993, six Old Fort Lake sediment samples were collected from randomly selected locations within a 100-foot grid system. All samples were located at least 50 feet from the low water line at the time of sampling. Two surface and subsurface composite samples were

collected from each of the six locations at depths of 0 to 2 cm and 2 to 15 cm. A diver collected the samples using a push-core sampler.

The sampling equipment was thoroughly decontaminated between each sampling location by scrubbing with an Alconox solution, followed by successive rinses with tap water and deionized water.

Marine sediment sample collection methods are discussed in Appendix D.

Sample Custody Documentation

This section discusses handling, labeling, and custody of soil, water, and sediment samples.

Sample Handling. Field samples were collected according to the procedures specified in the sections above. Preservation and storage measures for all samples were followed in general accordance with the Quality Assurance Project Plan (Section 5) in the RI/FS Management Plan (Hart Crowser, 1992a).

Sample Labeling. Sample numbers, date and time, sampler's initials, Hart Crowser job number, and other pertinent comments such as preservation were recorded on each sample label. To expedite sample collection, labels were generally filled out prior to sampling with only the time and date needing completion at the time of sampling.

Sample Custody. Custody records were maintained for all soil, water, and sediment samples collected during the RI. Samples were delivered by the Hart Crowser field representative to the laboratory, generally at the end of each sampling day, therefore the chain of custody form was signed only by the Hart Crowser representative and the laboratory representative.

Specifications for chemical analyses were made on the custody record under the Testing header. Other information listed on this form included date of sampling, sample designations, sampler's signature, Hart Crowser project name and job number, sample matrix, laboratory-assigned number, total number of sample containers, method of shipment, and any additional specialized instructions for sample holding, extraction, or analysis with reference to specific laboratory work orders. Copies of all chain of custody records are retained by Hart Crowser.

Hydrogeologic Data Collection

Water level monitoring, *in situ* hydraulic conductivity testing (slug testing), and short-term pumping tests were conducted to provide data on groundwater flow directions and rates. The equipment and field procedures used are discussed below.

Water Level Monitoring

Depth to water measurements in all groundwater and surface water locations were made every two months between April 1992 and December 1992. Water level measurements were

collected using an electric well probe and tape measure graduated in 0.01-foot increments. Depth to water below the top of surveyed measuring point on the top of the PVC well casing was recorded to 0.01 foot. The tip of the well probe was rinsed between each measurement. The water level data are presented in Table A-1.

In Situ Hydraulic Conductivity Testing (Slug Testing)

In situ hydraulic conductivity tests (slug tests) were conducted in 12 monitoring wells during the RI. Slug tests are the typical method for estimating hydraulic conductivity (K) of subsurface soils near a well, by measuring the rate of water level fall or rise in the well after the static water level is suddenly displaced.

In falling head slug tests, a 10-foot-long, 1.5-inch-diameter, solid PVC rod was "instantaneously" lowered into the well, causing a sudden rise in the water level. An automatic data acquisition system with downhole 7 psi pressure transducer recorded the falling water level over time as it re-equilibrated toward the static level. In the rising head tests, the situation was reversed; the slug rod was "instantaneously" withdrawn from the well, causing the water level to drop, followed by a water level rise to equilibrium. The slug rod and pressure transducer were decontaminated between the testing of different monitoring wells.

Because all monitoring wells tested are in aquifers under unconfined conditions, data from all tests were analyzed by the method of Bouwer and Rice (1976) for unconfined (water table) aquifer conditions. The water level response in newly installed monitoring wells MW-20 and MW-21 was too fast to provide any usable data for analysis. The results of the slug tests are provided in Section 3.1.

Short-Term Pumping Tests

In addition to the slug tests, short-term pumping tests were conducted in two selected monitoring wells. The primary reason these pumping tests were conducted instead of additional slug tests was that, by pumping continuously, a larger portion of the aquifer could potentially be stressed, resulting in more representative data.

In conducting the tests, a 2-inch-diameter submersible pump was placed near the bottom of the well casing. The automatic data logger's pressure transducer was placed as deep as possible above the pump. The pump was run at the maximum rate (4 to 5 gpm depending on lift) for approximately 45 minutes, during which time drawdown data were recorded automatically. The discharge rate was monitored frequently during pumping by measuring the time required to fill a 4-gallon bucket. After approximately 45 minutes, the pump was shut off and the water level recovery data were recorded until static conditions were achieved. The pump discharge hose and pressure transducer cable occupied most of the space within the monitoring well casing. Therefore, it was not possible to collect manual (well sounder) depth-to-water measurements as backup to the data logger readings. The 7 psi transducer was manufactured by Instrumentation Northwest (INW) of Redmond, Washington. The transducers are routinely sent back to INW for recalibration using a pressure cell apparatus.

The water produced during the pumping tests was collected in the drums also used for storing groundwater sampling purge water. This water was collected and pumped into on-site Baker Tanks (under the direction of DERS) for subsequent disposal.

All downhole development equipment was decontaminated before use and between wells. The decontamination consisted of scrubbing with Alconox solution, followed by a tap water rinse and a thorough spray with deionized water. In addition, the submersible pump was run submersed in an Alconox solution followed by tap water.

Data from all tests were analyzed by the Cooper-Jacob semi-logarithmic method (Cooper and Jacob, 1946). Because the monitoring wells were not designed to be hydraulically efficient, it is likely that a substantial portion of the drawdown observed during pumping may have been attributable to well loss. As a result, the recovery data (when pump was turned off) were generally considered more representative of aquifer response than the pumping data. The results of the pumping tests are provided in Section 3.1.

MONITORING WELL BORING LOGS AND CONSTRUCTION DATA

Key to Exploration Logs

Sample Description

Classification of soils in this report is based on visual field and laboratory observations which include density/consistency, moisture condition, grain size, and plasticity estimates and should not be construed to imply field nor laboratory testing unless presented herein. Visual-manual classification methods of ASTM D 2488 were used as an identification guide.

Soil descriptions consist of the following:
Density/consistency, moisture, color, minor constituents, MAJOR CONSTITUENT, additional remarks.

Density/Consistency

Soil density/consistency in borings is related primarily to the Standard Penetration Resistance.
Soil density/consistency in test pits is estimated based on visual observation and is presented parenthetically on the test pit logs.

SAND or GRAVEL Density	Standard Penetration Resistance (N) in Blows/Foot	SILT or CLAY Consistency	Standard Penetration Resistance (N) in Blows/Foot	Approximate Shear Strength in TSF
Very loose	0 – 4	Very soft	0 – 2	<0.125
Loose	4 – 10	Soft	2 – 4	0.125 – 0.25
Medium dense	10 – 30	Medium stiff	4 – 8	0.25 – 0.5
Dense	30 – 50	Stiff	8 – 15	0.5 – 1.0
Very dense	>50	Very stiff	15 – 30	1.0 – 2.0
		Hard	>30	>2.0

Moisture

Dry	Little perceptible moisture
Damp	Some perceptible moisture, probably below optimum
Moist	Probably near optimum moisture content
Wet	Much perceptible moisture, probably above optimum

Minor Constituents

	Estimated Percentage
Not identified in description	0 – 5
Slightly (clayey, silty, etc.)	5 – 12
Clayey, silty, sandy, gravelly	12 – 30
Very (clayey, silty, etc.)	30 – 50

Bottom of 5-HA-501 at 3 feet, completed 3/12/92.

Note:
5-HA-501 completed within the ditch below the southern of two former drain lines from the acid production area.

Log of Hand Auger Boring 5-HA-502
Ground Surface Elevation Approximately 173.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 1.5	(Loose), damp, black-brown, slightly silty, gravelly, medium to fine SAND with minor roots; rusted metal flakes in top 2 inches.
S-2(R)	3 to 4	5	1.5 to 4	(Medium dense), damp, light brown, sandy GRAVEL.

Bottom of 5-HA-502 at 4 feet, completed 3/9/92.

Log of Hand Auger Boring 5-HA-503
Ground Surface Elevation Approximately 174.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4.5	0 to 1	(Loose to medium dense), damp, red-brown, silty, gravelly, medium to fine SAND; abundant rusted metal flake in top 4 inches.
S-2(R)	2 to 3	4.5	1 to 3	(Medium dense), damp, brown, slightly silty, sandy GRAVEL.

Bottom of 5-HA-503 at 3 feet, completed 3/9/92.

Log of Hand Auger Boring 5-HA-504
Ground Surface Elevation Approximately 177.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4.5	0 to 3	(Dense), damp, light brown-gray, slightly sandy GRAVEL to 8-inch diameter.
S-2(R)	2 to 3	4.5		

Bottom of 5-HA-504 at 3 feet, completed 3/9/92.

Note:
5-HA-504 completed within the deep ditch below the northern of two former drain lines (with spillway) from the acid production area.

Log of Hand Auger Boring 5-HA-505
Ground Surface Elevation Approximately 193.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4	0 to 0.5	(Loose), damp, black, gravelly SAND mixed with cobbles.
			0.5 to 1.5	(Dense), damp, dark brown, sandy GRAVEL.
S-2(R)	2 to 3	4	1.5 to 3.5	(Dense), damp, light brown, sandy GRAVEL.

Bottom of 5-HA-505 at 3.5 feet, completed 3/10/92.

Log of Hand Auger Boring 5-HA-507
Ground Surface Elevation Approximately 176.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4	0 to 2	(Loose), purplish red, vitrified, granular FILL, with glass fragments and stained cobbles.
S-2(R)	2.5 to 3.5	5	2 to 3.5	(Medium dense), moist, brown, sandy GRAVEL.

Bottom of 5-HA-507 at 3.5 feet, completed 3/10/92.

Log of Hand Auger Boring 5-HA-508
Ground Surface Elevation Approximately 169.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4.5	0 to 3	(Dense), damp, brown, slightly silty, gravelly SAND with minor roots.
S-2(R)	2 to 3	5		

Bottom of 5-HA-508 at 3 feet, completed 3/10/92.

Log of Hand Auger and Boring 5-HA-509
Ground Surface Elevation Approximately 181.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 3	(Dense), damp, brown, slightly silty, gravelly, medium to fine SAND; organics in top 2 inches.
S-2(R)	2 to 3	4.5		

Bottom of 5-HA-509 at 3 feet, completed 3/10/92.

Log of Hand Auger Boring 5-HA-510
Ground Surface Elevation Approximately 182.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4	0 to 1	(Loose), damp, dark brown, slightly silty, gravelly, medium to fine SAND.
S-2(R)	2 to 3	4	1 to 3	(Dense), damp, brown, gravelly, medium to fine SAND.

Bottom of 5-HA-510 at 3 feet, completed 3/12/92.

Log of Hand Auger Boring 5-HA-512
Ground Surface Elevation Approximately 189.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4	0 to 1.5	(Loose), moist, black SAND; petroleum odor at 0 to 1 foot; ½ inch of oil on surface; bricks and rusted metal flakes from depths of 1 to 1.5 feet.
			1.5 to 2	(Medium dense), moist, purplish red, granular FILL with cobbles.
S-2(R)	2 to 3	4	2 to 3	(Medium dense), moist, light brown, gravelly SAND.

Bottom of 5-HA-512 at 3 feet, completed 3/26/92.

Log of Hand Auger Boring 5-HA-513
Ground Surface Elevation Approximately 191.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 0.5	Moist, dark brown, silty SAND with roots; plastic flakes at surface.
			0.5 to 2	Moist, brown, gravelly SAND.
S-2	2 to 3	5	2 to 3	Moist, orange-brown, sandy GRAVEL, oxidized.

Bottom of 5-HA-513 at 3 feet, completed 3/12/92.

Log of Hand Auger Boring 5-HA-514
Ground Surface Elevation Approximately 197.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), moist, brown, slightly sandy to sandy GRAVEL.
S-2	2 to 3	4		

Bottom of 5-HA-514 at 3 feet, completed 3/12/92.

Log of Hand Auger Boring 5-HA-515
Ground Surface Elevation Approximately 172.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 1	(Loose), moist, brown, sandy GRAVEL.

Bottom of 5-HA-515 at 3 feet, completed 3/12/92.

Log of Hand Auger Boring 5-HA-516
Ground Surface Elevation Approximately 194.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2.5	(Loose), moist, brown, silty, gravelly, medium to fine SAND.
S-2	2 to 3	4	2.5 to 3	(Dense), moist, light brown, sandy GRAVEL.

Bottom of 5-HA-516 at 3 feet, completed 3/12/92.

Log of Hand Auger Boring 5-HA-517
Ground Surface Elevation Approximately 188.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), moist, brown, silty, gravelly, medium to fine SAND.
S-2	2 to 3	5	1 to 3	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 5-HA-517 at 3 feet, completed 3/12/92.

AREA 6
EXPLORATION LOGS

Log of Test Pit 6-TP-501
Ground Surface Elevation Approximately 200.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Medium dense), moist, medium brown, silty, sandy GRAVEL with abundant bricks, mortar, and metal piping (FILL)
S-2	3 to 6	5	2.5 to 6	(Dense), moist, light brown, sandy GRAVEL with abundant bricks and mortar (FILL)
S-3	8 to 10	5	6 to 10	(Dense), moist, light brown, sandy GRAVEL

Bottom of 6-TP-501 at 10 feet, completed 4/20/92.

Notes:
1) 4-foot-long, 3-inch-diameter steel casing exposed in side wall of test pit. Casing full of soil.
2) Test pit excavated along south side of former Ammonia Nitrate Crystallizer foundation. Concrete wall of foundation extended to depth of 6 feet in north wall of excavation.

Log of Test Pit 6-TP-502
Ground Surface Elevation Approximately 198.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), moist, light brown, very sandy GRAVEL
S-2	3 to 6	5	1 to 10	(Dense), moist, light brown, sandy GRAVEL with interbedded layers of GRAVEL (native)
S-3	8 to 10	5		

Bottom of 6-TP-502 at 10 feet, completed 4/20/92.

AREA 7
EXPLORATION LOGS

Boring Log 7-B-501

Soil Descriptions

Ground Surface Elevation in Feet 179.6

(Loose), moist, black, slightly silty, sandy GRAVEL.

Medium dense, moist, greenish gray, slightly sandy GRAVEL.

Faint sulfurous odor.

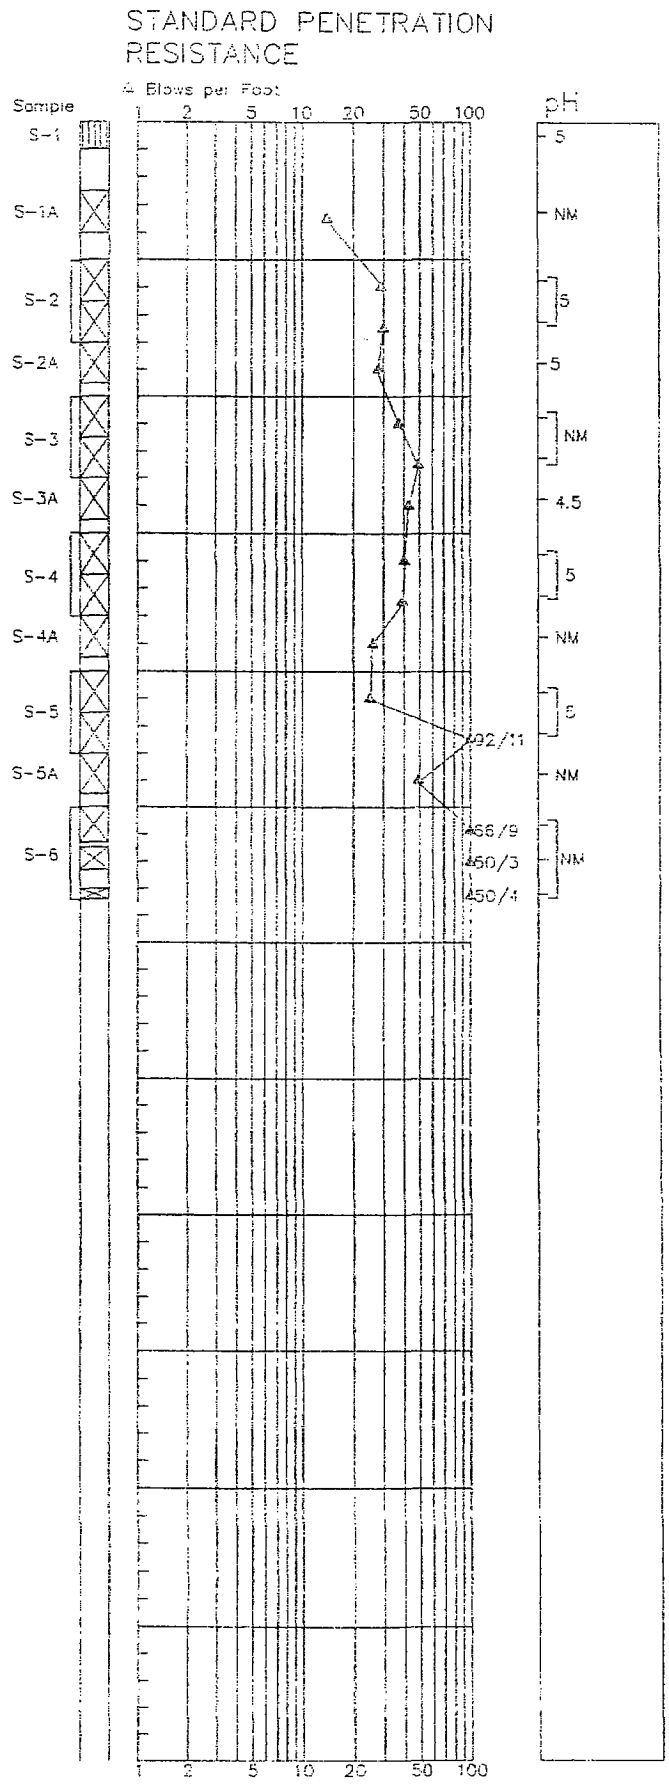
Dense, moist, gray, sandy GRAVEL.

Faint sulfurous odor and greenish staining on gravels.

Medium dense, moist, gray, medium to fine SAND.

Very dense, moist, gray, sandy to slightly sandy GRAVEL with minor yellow and green staining on gravels.

Bottom of Boring at 28.3 Feet. Completed 2/28/92



1. Refer to Figure A-1 for explanation of descriptions and symbols.
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-7-4 1/1

Log of Test Pit 7-TP-501
Ground Surface Elevation Approximately 185.9 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 0.5	(4 inches of forest duff over medium dense), moist, dark brown, sandy GRAVEL with abundant roots and grass.
S-2	3 to 6	4.5	0.5 to 10	(Medium dense), damp, silvery gray, slightly sandy to sandy GRAVEL with boulders to 1 foot and some green staining on gravels. Discontinuous 3-inch-thick layer of Bunker C oil staining at depth of 0.5 foot. Thin gravel lens at depth of 1.5 feet. Distinct zone of yellowish green staining on gravels between depths of 8 and 9 feet.
S-3	8 to 10	4		

Bottom of 7-TP-501 at 10 feet, completed 3/5/92.

Log of Test Pit 7-TP-502
Ground Surface Elevation Approximately 179.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	Two inches of grass and organic debris over (medium dense), moist, brown, slightly silty, sandy GRAVEL with abundant roots.
S-2	3 to 6	5	2 to 10	(Medium dense), moist, grayish brown, sandy GRAVEL with 6-inch-thick gravel lens at a depth of 5.5 feet.
S-3	8 to 10	5		

Bottom of 7-TP-502 at 10 feet, completed 3/5/92.

Log of Test Pit 7-TP-503
Ground Surface Elevation Approximately 176.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2.5	One inch of grass and organic debris over (medium dense), moist, light brownish gray, sandy GRAVEL with occasional roots. Two-inch-thick lens of moist, black, slightly silty, gravelly SAND at 1.25 feet depth. Four-inch-thick lens of moist, black, silty SAND at 2.5 feet depth.
S-2	3 to 6	4	2.5 to 5	(Medium dense), moist, gray and light brown, very silty, fine SAND.
S-3	8 to 10	4	5 to 10	(Medium dense), moist, gray, sandy GRAVEL with rust and yellow staining between depths of 7 and 9 feet.

Bottom of 7-TP-503 at 10 feet, completed 3/5/92.

Log of Test Pit 7-TP-504
Ground Surface Elevation Approximately 181.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2	Four inches of black, silty, slightly gravelly SAND with abundant roots over (loose), moist, brown, slightly gravelly, silty SAND.
			2 to 3.5	(Medium dense), moist, brownish gray, very sandy SILT.
S-2	3 to 6	5	3.5 to 7.5	(Medium dense), moist, brown, very sandy GRAVEL.
S-3	8 to 10	5	7.5 to 10	(Medium dense), moist, brown, gravelly SAND.

Bottom of 7-TP-504 at 10 feet, completed 3/5/92.

Log of Observation Test Pit 7-OB-TP-501
Ground Surface Elevation Approximately 171.7 Feet

Sample Number	Stratum Depth in Feet*	Soil Description
No samples collected	0 to (1-3)	(Loose), damp, gray, silty, sandy GRAVEL (FILL).
	(1-3) to (2-7)	(Soft), moist, gray SILT (Sludge-like FILL), some burnt wood fragments found in upper section of silt layer.
	(2-7) to (5-8)	(Medium dense), moist, gray-brown, sandy GRAVEL (Native?).

Bottom of 7-OB-TP-501 at 8.0 feet, completed 6/29/92.

Notes:
1) Observational test pit; no samples collected.
2) *: The strata in 7-OB-TP-501 dip in a northerly direction toward middle of kettle. Therefore, stratum top and bottom depths are variable across the excavation, and are indicated with a range of depths in parentheses.
3) Test pit excavation approximately 20 feet in length, oriented from southeast corner of kettle toward kettle center.

Log of Observation Test Pit 7-OB-TP-502
Ground Surface Elevation Approximately 181.1 Feet

Sample Number	Sample Depth in Feet	Soil Description
No samples collected		(Loose), damp, gray and bleached white, sandy GRAVEL with slight sulfur odor and area of green and yellow stained rocks at depth of 2 to 4.5 feet in center of excavation. Brown, sandy GRAVEL (appears native) observed in upper 2 feet along western edge of excavation.

Bottom of 7-OB-TP-502 at 6.0 feet, completed 6/29/92.

Notes:
1) Observational test pit; no samples collected.
2) Observed layer of Bunker C oil staining near surface at southwest end of test pit.
3) Test pit excavation approximately 20 feet in length, oriented east-west.

Log of Hand Auger Boring 7-HA-501
Ground Surface Elevation Approximately 201.4 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Medium dense), damp, light brown, silty, sandy GRAVEL.
S-2	1 to 2		
S-3	2 to 3		

Bottom of 7-HA-501 at 3.0 feet, completed 6/29/92.

Note:
Observed Bunker C oil staining just beneath layer of moss at surface.

Log of Hand Auger Boring 7-HA-502
Ground Surface Elevation Approximately 183.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 0.5	(Medium dense), damp, light brown, sandy GRAVEL with grass roots.
S-2	1 to 2	0.5 to 2.0	(Medium dense), damp, gray, sandy GRAVEL.
S-3	2 to 3	2 to 3	(Loose), damp, gray, gravelly SAND with tree roots.

Bottom of 7-HA-502 at 3.0 feet, completed 7/1/92.

Log of Hand Auger Boring 7-HA-503
Ground Surface Elevation Approximately 201.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Medium dense), damp, light brown, silty, sandy GRAVEL
S-2	1 to 2		
S-3	2 to 3		

Bottom of 7-HA-503 at 3.0 feet, completed 6/29/92.

Note:
Observed Bunker C oil staining in upper 3 inches of soil.

Log of Hand Auger Boring 7-HA-504
Ground Surface Elevation Approximately 180.6 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Medium dense), damp, brown to tan, silty, sandy GRAVEL.
S-2	1 to 2		
S-3	2 to 3		

Bottom of HA-504 at 3.0 feet, completed 6/29/92.

AREA 10
EXPLORATION LOGS

Log of Test Pit 10-TP-501
Ground Surface Elevation Approximately 210 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 2	(Medium dense), moist, black, slightly silty, sandy GRAVEL with a lid from a 55-gallon drum at surface.
S-2	3 to 6	2 to 7	(Medium dense), moist, tan-brown, sandy GRAVEL
S-3	7 to 9	7 to 9	(Medium dense), moist, tan-brown, slightly gravelly SAND

Bottom of 10-TP-501 at 9 feet, completed 2/24/92.

2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-12-1 1/1

Boring Log 12-1-B-501A

Soil Descriptions

(Medium dense), moist, dark brown, slightly silty, very gravelly SAND.

Grades to sandy GRAVEL.

Medium dense, moist to wet, dark brown to brown, very sandy GRAVEL with plastic water gel bags from 5- to 6-foot depth.

Dense, moist, brown, very sandy GRAVEL.

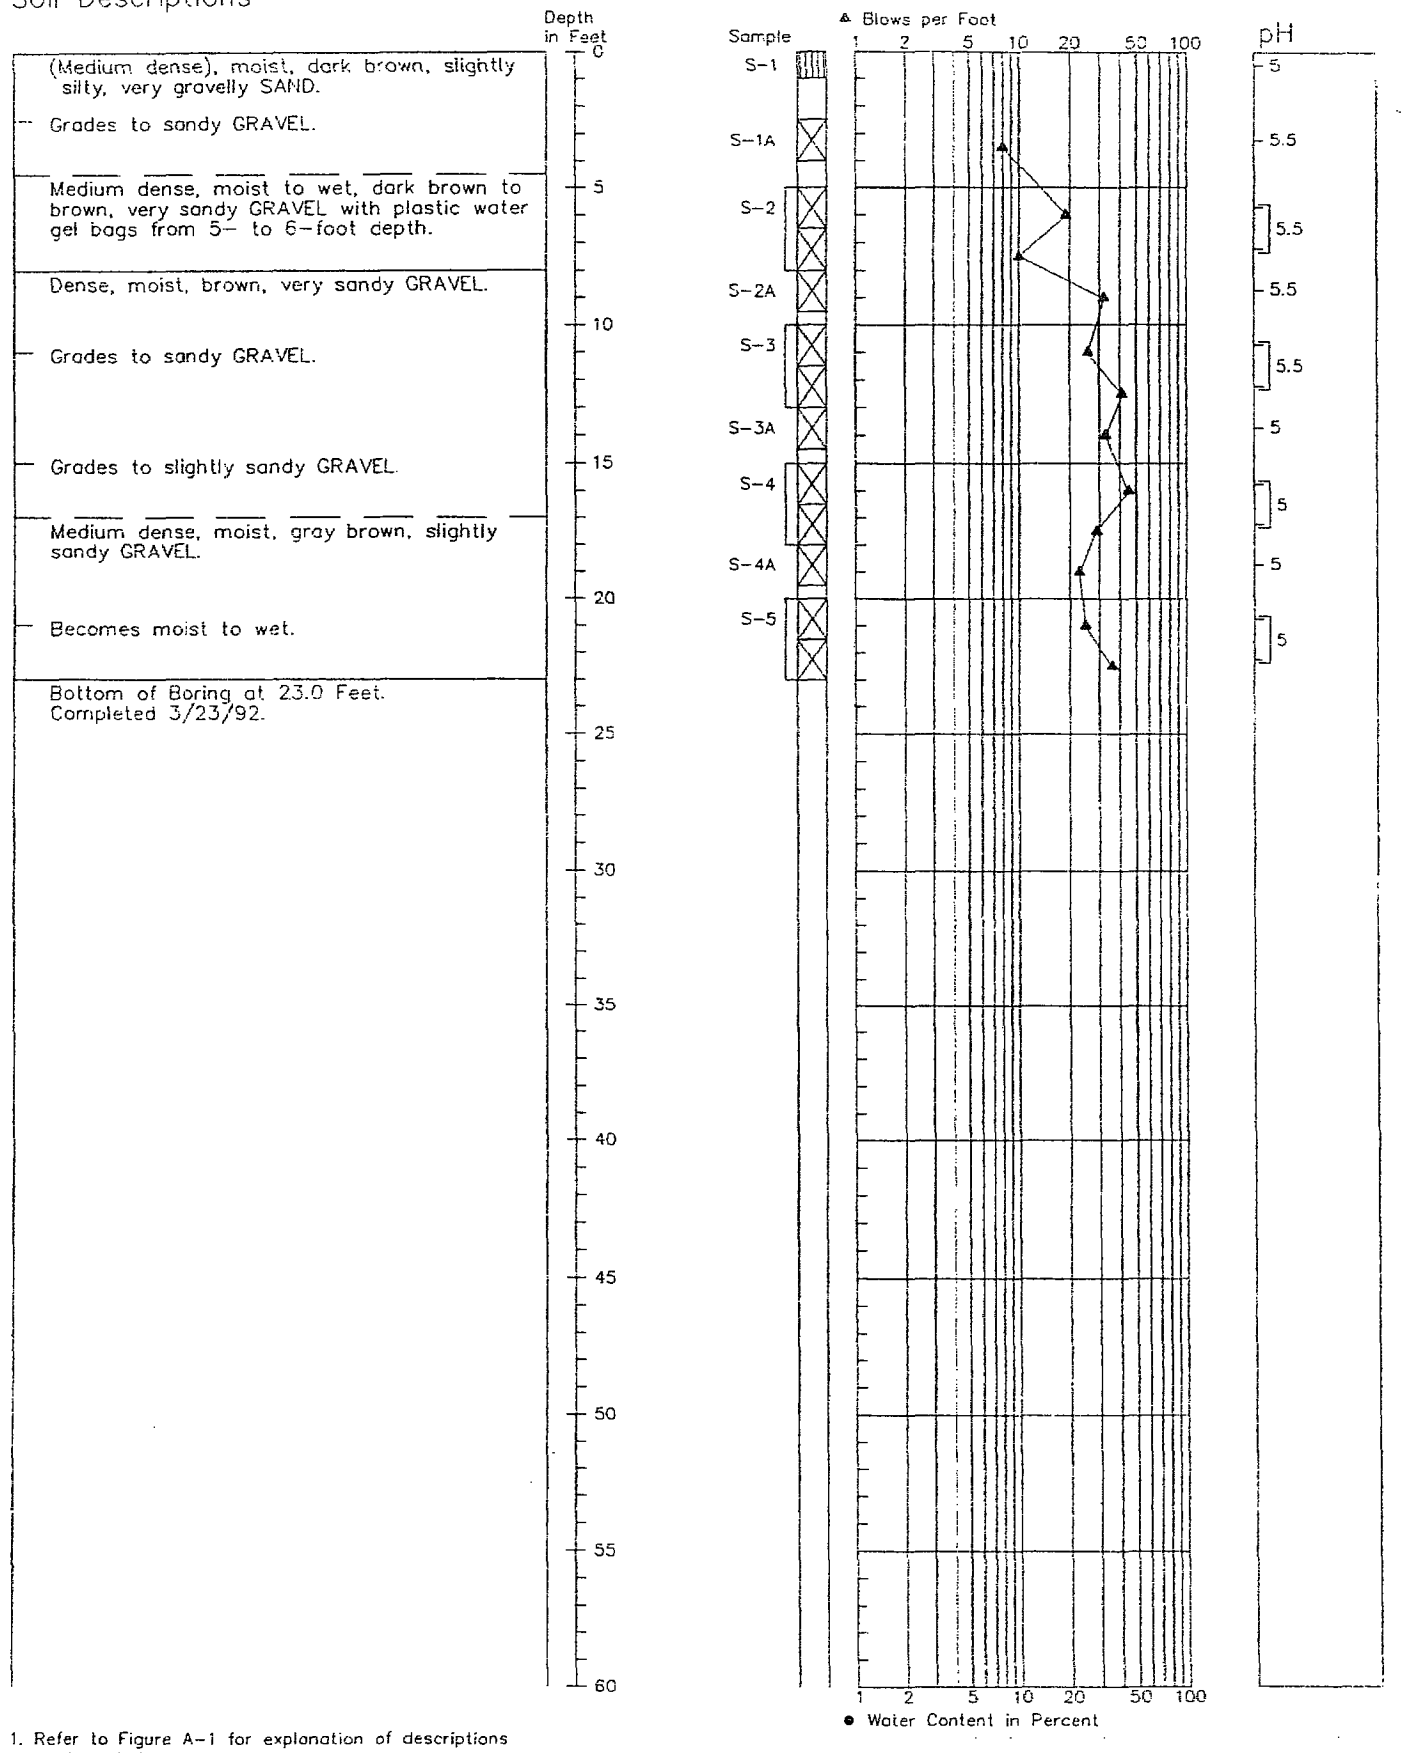
Grades to sandy GRAVEL.

Grades to slightly sandy GRAVEL.

Medium dense, moist, gray brown, slightly sandy GRAVEL.

Becomes moist to wet.

Bottom of Boring at 23.0 Feet.
Completed 3/23/92.



1. Refer to Figure A-1 for explanation of descriptions and symbols.
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-12-2 1/1

Boring Log 12-2-B-501

Soil Descriptions

Ground Surface Elevation in Feet 215.6

(Medium dense) to dense, moist, black to dark brown, silty, very sandy GRAVEL to sandy GRAVEL with abundant debris (plastic, water gel bags and nylon netting).

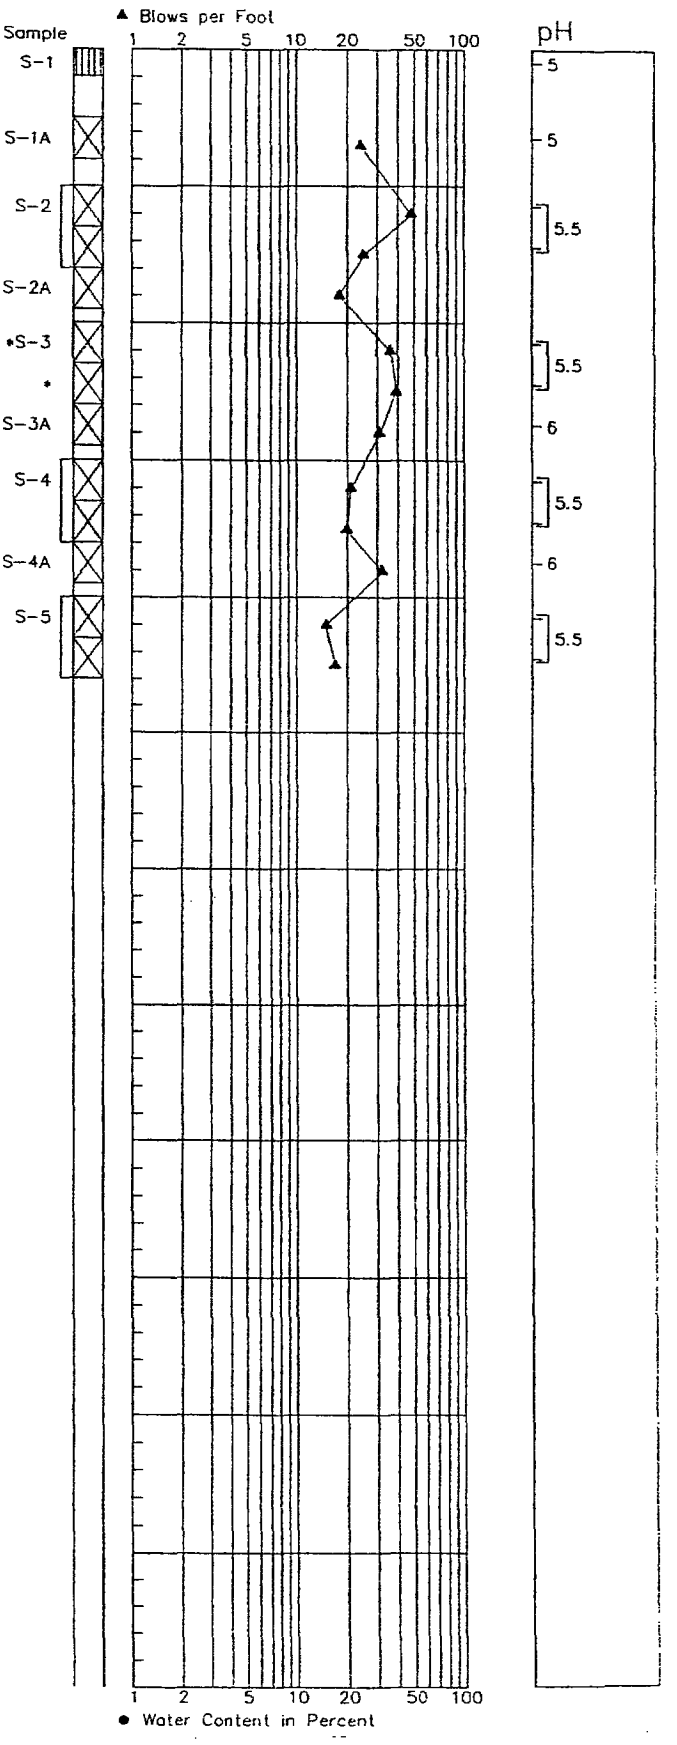
Medium dense to dense, moist, grayish brown, sandy GRAVEL with aluminum cans and plastic.

Medium dense, moist, brown, gravelly SAND.

Dense to medium dense, moist, gray-brown, very sandy to sandy GRAVEL.

Becomes moist to wet.

Bottom of Boring at 23.0 Feet.
Completed 3/24/92.



1. Refer to Figure A-1 for explanation of descriptions and symbols.
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-12-3 1/1

Boring Log 12-2-B-502

Soil Descriptions

Ground Surface Elevation in Feet 213.1

(Medium dense) to loose, moist, medium to dark brown, sandy GRAVEL.

Wood fragments and brown paper.

Pieces of old hydraulic lines.

Medium dense, moist, grayish brown, sandy GRAVEL.

Dense to very dense, moist, dark gray, slightly sandy to sandy GRAVEL.

Dense, moist to wet, rust colored, slightly sandy to sandy GRAVEL.

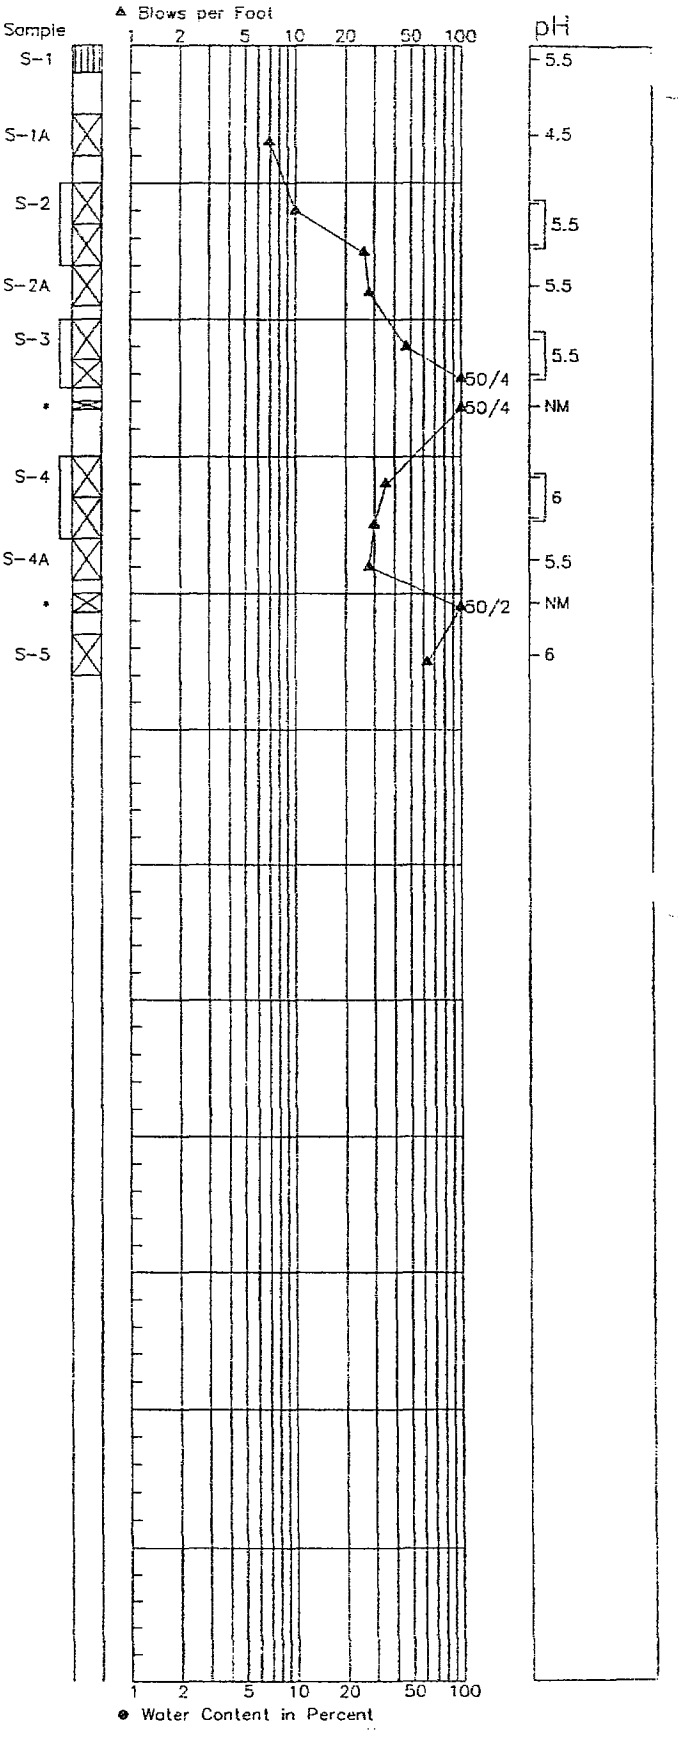
Brown-gray

Very dense, moist, brownish gray, very gravelly SAND.

Bottom of Boring at 23.0 Feet.
Completed 3/24/92.

Depth in Feet: 0, 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60

STANDARD PENETRATION RESISTANCE



1. Refer to Figure A-1 for explanation of descriptions and symbols.
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-12-4 1/1

Boring Log 12-6-B-501

Soil Descriptions

Ground Surface Elevation in Feet 226.2

Depth in Feet

Grass sod over (medium dense), moist, dark brown, slightly silty, very gravelly SAND.

Small brick fragments.

Dense, moist, brown, sandy GRAVEL.

Medium dense, moist to wet, grayish brown, sandy GRAVEL.

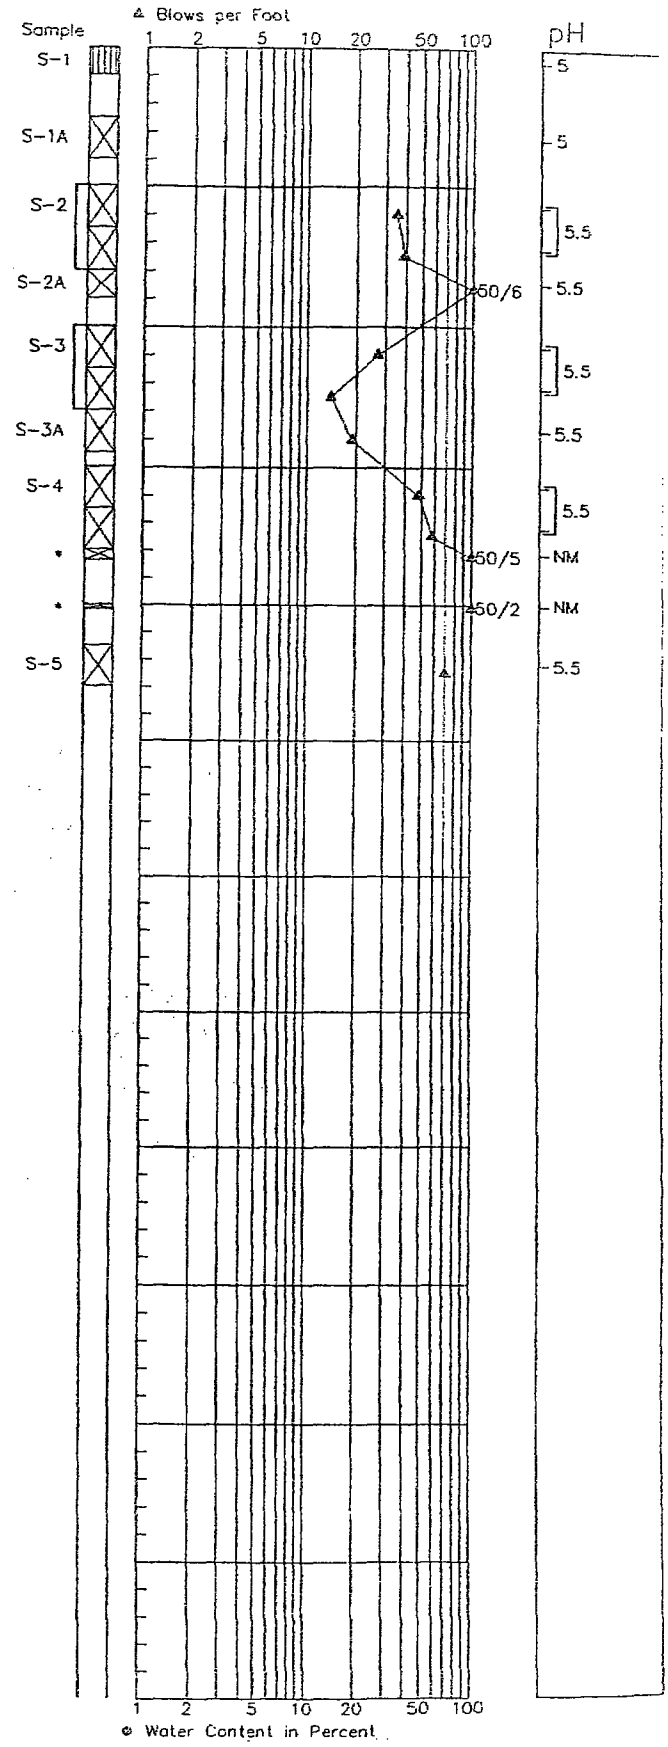
Dense, moist, brown, slightly silty, sandy GRAVEL to sandy GRAVEL.

Very dense, moist to wet, brown, slightly silty, medium to fine SAND.

Bottom of Boring at 23.0 Feet.
Completed 3/25/92.

0 5 10 15 20 25 30 35 40 45 50 55 60

STANDARD PENETRATION RESISTANCE



1. Refer to Figure A-1 for explanation of descriptions and symbols.
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-12-5 1/1

Boring Log 12-7-B-501

Soil Descriptions

Ground Surface Elevation in Feet 225.3

Depth in Feet

Sod over (medium dense), moist, dark brown, slightly silty, gravelly SAND.

Dense, moist, brown, gravelly SAND to sandy GRAVEL.

Medium dense to dense, moist, brown, slightly silty, sandy GRAVEL to gravelly SAND

Dense to medium dense, moist to wet, brown, slightly silty, sandy GRAVEL.

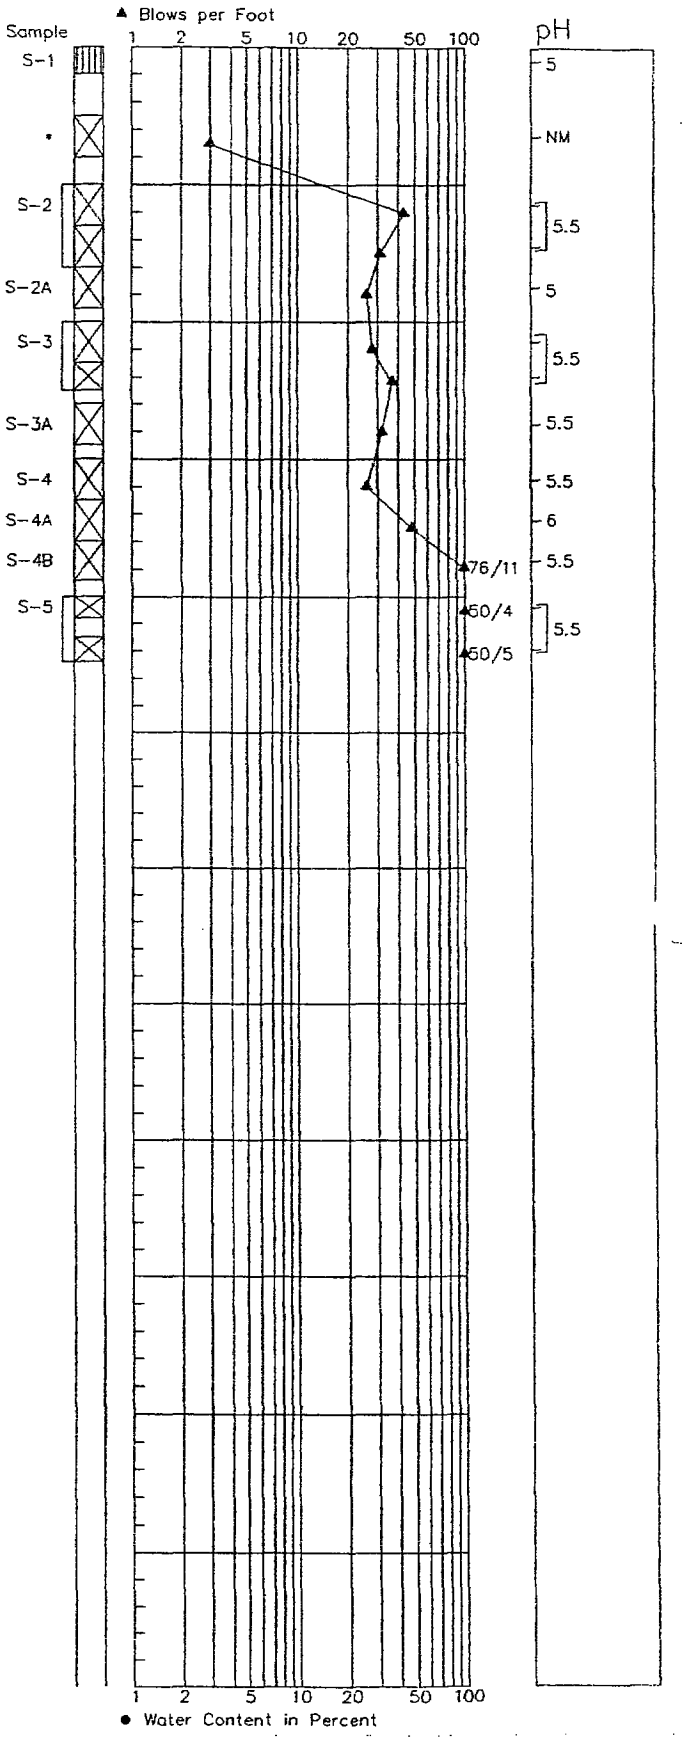
Dense to very dense, moist, brown, sandy GRAVEL.

Very dense, moist to wet, brown, sandy GRAVEL with silt covered gravels.

Bottom of Boring at 23.0 Feet.
Completed 3/25/92.

0 5 10 15 20 25 30 35 40 45 50 55 60

STANDARD PENETRATION RESISTANCE



1. Refer to Figure A-1 for explanation of descriptions and symbols.
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-12-6 1/1

Log of Test Pit 12-1-TP-501
Ground Surface Elevation Approximately 215.6 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 0.5	(Loose), moist, dark brown, sandy GRAVEL (FILL).
		0.5 to 2.5	(Loose), moist, brown, sandy GRAVEL with abundant debris (FILL) (see note below).
		2.5 to 3	(Loose), moist, black, silty, sandy GRAVEL (possibly NATIVE).
S-2	3 to 6	3 to 10	(Loose), moist, brown, sandy GRAVEL (NATIVE).
S-3	8 to 10		

Bottom of 12-1-TP-501 at 10 feet, completed 4/13/92.

Notes:

1) Debris observed from 1 to 3 feet: apparently empty, white, water gel, plastic bags.
2) Observed plastic banding (strapping), steel banding, and plastic 55-gallon drum liners.

Log of Test Pit 12-1-TP-502
Ground Surface Elevation Approximately 215.4 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 0.5	(Loose), moist, dark brown, silty, sandy GRAVEL.
S-2	3 to 6	0.5 to 10	(Loose), moist, brown, slightly sandy GRAVEL with occasional interbedded gravel layers.
S-3	8 to 10		

Bottom of 12-1-TP-502 at 10 feet, completed 4/13/92.

Log of Test Pit 12-1-TP-503
Ground Surface Elevation Approximately 216.3 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1	(Loose), moist, dark brown, slightly silty, sandy GRAVEL.
S-2	3 to 6	1 to 10	(Loose), moist, brown, slightly sandy, cross-bedded GRAVEL.
S-3	8 to 10		

Bottom of 12-1-TP-503 at 10 feet, completed 4/13/92.

Log of Test Pit 12-1-TP-504
Ground Surface Elevation Approximately 214.2 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	(Loose), moist, black, silty, gravelly SAND.
S-2	3 to 6	1.5 to 10	(Loose), moist, medium brown, slightly sandy GRAVEL with cross-bedded gravel layers.
S-3	8 to 10		

Bottom of 12-1-TP-504 at 10 feet, completed 4/13/92.

Log of Observation Test Pit 12-1-OB-TP-501
Ground Surface Elevation Approximately 217.2 Feet

Sample Number	Stratum Depth in Feet	Soil Description
Not Sampled	0 to 1.5	6 inches of grass sod with scattered white plastic over water gel bags (empty) over (medium dense), moist, black, slightly silty, very gravelly SAND with moderate organics (roots, etc.) (NATIVE).
	1.5 to 3	(Dense), moist, brown, sandy to very sandy GRAVEL (NATIVE).

Bottom of 12-1-OB-TP-501 at 3 feet, completed 4/14/92.

Notes:
1) Soils appear native below 0.5 foot.
2) No samples collected (observational test pit).

Log of Observation Test Pit 12-1-OB-TP-502
Ground Surface Elevation Approximately 218.0 Feet

Sample Number	Stratum Depth in Feet	Soil Description
No Samples Collected	0 to 1.5	Six inches of grass sod with clear plastic bag, old tire, and logging debris over (medium dense), moist, black, slightly silty, gravelly SAND with moderate organics (NATIVE).
	1.5 to 3	(Dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-1-OB-TP-502 at 3 feet, completed 4/14/92.

Notes:
1) Soils below 0.5 foot appear native.
2) No residual water gel noted in empty plastic bag.
3) No samples collected (observational test pit).

Log of Observation Test Pit 12-1-OB-TP-503
Ground Surface Elevation Approximately 221.7 Feet

Sample Number	Stratum Depth in Feet	Soil Description
No Samples Collected	0 to 1.7	6 inches of sod with one plastic water gel bag, partially exposed, over (medium dense), moist, black, slightly silty, gravelly SAND (NATIVE).
	1.7 to 3.5	(Dense), moist, brown, very sandy GRAVEL (NATIVE).

Bottom of 12-1-OB-TP-503 at 3.5 feet, completed 4/14/92.

Notes:
1) Soils appear native below 0.5 foot.
2) No residual water gel in empty plastic bag.
3) No samples collected (observational test pit).

Log of Test Pit 12-2-TP-501
Ground Surface Elevation Approximately 214.7 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 7	(Loose), moist, black and brown, stratified, sandy GRAVEL with abundant debris (FILL) (see note below).
S-2	3 to 6		
		7 to 8	(Loose), moist, black, silty, sandy GRAVEL (possibly NATIVE).
S-3	8 to 10	8 to 10	(Loose), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-2-TP-501 at 10 feet, completed 4/13/92.

Note:
Debris observed from 1.5 to 7.3 feet: old truck tire, assorted metal debris, metal banding, potential asbestos-containing material, plastic bags (unmarked), 2-inch-diameter rubber hose, tin and aluminum cans, foam rubber, plastic banding, various rubber and paper debris, wood debris (RR ties), abundant stacks of wax-covered cardboard, and a firehose.

Log of Test Pit 12-2-TP-502
Ground Surface Elevation Approximately 214.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6.5	(Medium dense), moist, dark brown, sandy GRAVEL with roots in top foot and abundant debris (FILL) (see note below).
S-2	3 to 6	4		
S-3	8 to 10	4	6.5 to 10	(Medium dense), moist, light brown, sandy GRAVEL (NATIVE).

Bottom of 12-2-TP-502 at 10 feet, completed 4/14/92.

Note:
Debris observed included abundant plastic strapping and a few clear plastic bags from depth of 1 to 3.5 feet. Plastic bag with scraps of metal, apparently a drum liner with a lid, from depth of 4 to 6 feet. No residual water gel observed in bags.

Log of Test Pit 12-2-TP-503
Ground Surface Elevation Approximately 215.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 1	(Medium dense), moist, brownish gray, sandy GRAVEL, with small scraps of cloth (FILL).
S-2	2 to 4	4	1 to 7	(Medium dense), moist, dark brown-black, sandy GRAVEL, with abundant debris (FILL) (see Note 1 below).
S-3	2.5	4		
S-4	4 to 6	5.5		
S-5	8 to 10	5.5	7 to 10	(Medium dense), moist, tan-brown, sandy GRAVEL (NATIVE).

Bottom of 12-2-TP-503 at 10 feet, completed 4/14/92.

Notes:
1) Debris observed from depth of 1 to 6 feet: few boards (1.5 feet long) with some plastic-coated paper, drum liner, old smashed drum (scraps of metal mesh and strapping) which had no odor or product, abundant clear plastic, some water gel bags (one bag had apparent residual water gel present), lump of grayish clay, pieces of plywood, yellow (resin-like) substance, old tire, rope fibers, empty white water gel bags, and assorted wood debris.
2) Sample S-3 was a discrete sample near apparent residual water gel.

Log of Test Pit 12-2-TP-504
Ground Surface Elevation Approximately 217.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Medium dense), moist, black, slightly silty, very sandy GRAVEL with roots from 0 to 1 foot and debris (FILL) (see note below).
S-2	3 to 6	5	3 to 10	(Medium dense), moist, tan-brown, sandy GRAVEL with interbedded gravel layers (NATIVE).
S-3	8 to 10	4		

Bottom of 12-2-TP-504 at 10 feet, completed 4/14/92.

Note:
Debris observed from depth of 1.5 to 3.0 feet: old log, few pieces of metal strapping, and a knotted ball of black plastic strapping.

Log of Test Pit 12-2-TP-505
Ground Surface Elevation Approximately 213.9 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 9	(Medium dense), moist, dark brown, sandy GRAVEL with debris and noticeable creosote odor (FILL) (see note below).
S-2	3 to 6	4.5		
S-3	9 to 10	4.5	9 to 10	(Medium dense), moist, medium gray, sandy GRAVEL (NATIVE).

Bottom of 12-2-TP-505 at 10 feet, completed 4/14/92.

Note:
Debris observed from depth of 1 to 3 feet: many wooden posts (strong creosote odor), 6-foot-long rubber hose, metal banding, occasional tin cans and scraps of plastic, sheets of plastic, and thick cardboard.

Log of Test Pit 12-2-TP-506
Ground Surface Elevation Approximately 213.9 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6	(Medium dense), moist, black, silty, gravelly SAND with debris from 1.3 to 6 feet (FILL) (see note below).
S-2	3 to 6	4.5		
S-3	8 to 10	4.5	6 to 10	(Medium dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-2-TP-506 at 10 feet, completed 4/15/92.

Note:
Debris observed from depth of 1.3 to 6 feet: abundant cardboard, 4-inch-diameter pipe (plastic and steel), concrete, plaster, tin cans, steel garbage can, and aluminum roofing; decomposing cardboard had hydrogen sulfide odor.

Log of Observation Test Pit 12-2-OB-TP-501
Ground Surface Elevation Approximately 210.3 Feet

Sample Number	Stratum Depth in Feet*	Soil Description
No Samples Collected	0 to (0.8- 1.5)	(Medium dense), moist, black, slightly silty, gravelly SAND with black, 3/4-inch rusted steel banding at approximately 0.5 foot (FILL).
	(0.8-1.5) to 2	(Dense), moist, brown, very gravelly SAND (NATIVE).

Bottom of 12-2-OB-TP-501 at 2.0 feet, completed 4/14/92.

Notes:
1) *: Fill/native soil contact dips toward the east (contact depth at 0.8 foot at west end of pit; 1.5 feet at east end). Variable depths across test pit indicated as range in parentheses.
2) No samples collected (observational test pit).

Log of Observation Test Pit 12-2-OB-TP-502
Ground Surface Elevation Approximately 209.3 Feet

Sample Number	Stratum Depth in Feet	Soil Description
No Samples Collected	0 to 0.5	(Medium dense), moist, black, slightly silty, gravelly SAND (FILL?).
	0.5 to 2.5	(Dense), moist, brown, very sandy, stratified GRAVEL and very gravelly SAND (NATIVE).

Bottom of 12-2-OB-TP-502 at 2.5 feet, completed 4/14/92.

Notes:
1) Soils below 0.5 foot appear native.
2) No residual water gel observed in empty water gel bag located on surface next to excavation.
3) No samples collected (observational test pit).

Log of Observation Test Pit 12-2-OB-TP-503
Ground Surface Elevation Approximately 212.3 Feet

Sample Number	Stratum Depth in Feet	Soil Description
No Samples Collected	0 to 0.8	(Medium dense), moist, black, slightly silty, gravelly SAND (appears disturbed - FILL?).
	0.8 to 2.5	(Dense), moist, brown, very sandy GRAVEL (appears NATIVE).

Bottom of 12-2-OB-TP-503 at 2.5 feet, completed 4/14/92.

Note:
No samples collected (observational test pit).

Log of Observation Test Pit 12-2-OB-TP-504
Ground Surface Elevation Approximately 214.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	1 to 2	5	0 to 1.5	(Medium dense), moist, brown, sandy GRAVEL with debris from 0.5 to 1.5 feet (FILL) (see Note 1 below).
S-2	2 to 4	5	1.5 to 2.5	(Medium dense), moist, black, slightly silty, gravelly SAND with wood debris (FILL).
			2.5 to 6	(Medium dense), moist, dark brown, sandy to very sandy GRAVEL with minor debris (FILL) (see Note 2 below).
S-3	6 to 7	5	6 to 7	(Dense), moist, brown, very sandy GRAVEL (NATIVE).

Bottom of 12-2-OB-TP-504 at 7 feet, completed 4/15/92.

Notes:
1) Debris found from depth of 0.5 to 1.5 feet: flat waxed cardboard boxes and three unlabeled empty plastic drum liners.
2) Debris found from depth of 2.5 to 6.0 feet: scattered waxed cardboard pieces, plastic banding, and white plastic up to 6 by 6 inches.

Log of Observation Test Pit 12-2-OB-TP-505
Ground Surface Elevation Approximately 215.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	1 to 2	5	0 to 5.5	(Loose), moist, brown and black (interbedded), sandy GRAVEL with debris (FILL) (see note below).
S-2	2 to 4	5		
S-3	5.5 to 6.5	5	5.5 to 6.5	(Medium dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-2-OB-TP-505 at 6.5 feet, completed 4/15/92.

Note:
Debris observed from depth of 0.6 to 5.5 feet: bottles and cans, metal banding, wood debris, one 5-gallon can (crushed), plastic, thick cardboard, and apparently empty water gel bags.

Log of Test Pit 12-3-TP-501
Ground Surface Elevation Approximately 217.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet*	Soil Description
S-1	0 to 1	4.5	0 to (2 - 4)	(Loose), black, moist, silty, gravelly SAND with debris (FILL) (see Note 1 below).
S-2	2 to 4	4.5		
S-3	8 to 10	4.5	(2 - 4) to 10	(Medium dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-3-TP-501 at 10 feet, completed 4/15/92.

Notes:
1) Debris observed from depth of 0.5 to 4 feet: water gel bags containing residual water gel, wood debris (timbers), 55-gallon drum plastic liners, metal and plastic banding, strips of plastic, and white chalk-like material ("possibly nitric emulsion" per former DuPont employee).
2) Debris appeared to be approximately 60% of fill material from depth of 0.5 to 6 feet.
*: Fill/native soil contact depth is variable within excavation from 2 feet near east and west edges of pit to 4 feet in pit center. Depth range across test pit is indicated in parentheses.

Log of Test Pit 12-3-TP-502
Ground Surface Elevation Approximately 217.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6	(Loose), moist, black, silty, sandy GRAVEL mixed with debris (FILL) (see Note 1 below).
S-2	2 to 4	4.5		
S-3	4 to 6	4.5		
S-4	8 to 10	4.5	6 to 10	(Medium dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-3-TP-502 at 10 feet, completed 4/15/92.

Notes:
1) Debris observed from depth of 0.5 to 6 feet: water gel bags with small quantities of residual water gel, minor wood debris, green plastic tubes (4-inch-diameter), cardboard, and metal banding.
2) Small amount of water accumulation at 6 feet due to water retention in the plastic debris.
3) Debris observed to be confined to former trench. Native soil observed on east and west sides of test pit, surrounding the former trench.

Log of Test Pit 12-3-TP-503
Ground Surface Elevation Approximately 216.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 6	(Loose), black, moist, silty, sandy GRAVEL mixed with debris (FILL) (see Note 1 below).
S-2	3 to 6	4.5		
S-3	8 to 10	4.5	6 to 10	(Dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-3-TP-503 at 10 feet, completed 4/15/92.

Notes:
1) Debris observed from depth of 0.5 to 6 feet: white and clear plastic apparently empty water gel bags, minor cardboard, wood debris, 1-inch-diameter plastic tubing, one empty fertilizer paper bag.
2) Debris observed to be confined to former trench. Native soil observed on east and west sides of test pit, surrounding the former trench.

Log of Observation Test Pit 12-3-OB-TP-501
Ground Surface Elevation Approximately 217.1 Feet

Sample Number	Stratum Depth in Feet	Soil Description
No Samples Collected	0 to 2	(Medium dense), moist, black, slightly silty, very sandy GRAVEL with roots and minor metal and plastic scraps in north end of excavation (FILL).
	2 to 2.7	(Medium dense), moist, tan-brown, sandy GRAVEL (NATIVE).

Bottom of 12-3-OB-TP-501 at 2.7 feet, completed 4/16/92.

Notes:
1) No samples collected (observational test pit).
2) North wall of excavation appears to be the end of landfill trench.

Log of Observation Test Pit 12-3-OB-TP-502
Ground Surface Elevation Approximately 217.7 Feet

Sample Number	Stratum Depth in Feet	Soil Description
No Samples Collected	0 to 1.8	(Medium dense), moist, black, slightly silty, sandy GRAVEL (FILL?).
	1.8 to 2.7	(Medium dense), moist, tan-brown, sandy GRAVEL (NATIVE).

Bottom of 12-3-OB-TP-502 at 2.7 feet, completed 4/16/92.

Note:
Apparent FILL material (no debris observed) is confined to center of test pit. Native soils (brown, sandy GRAVEL) observed on east and west sides of apparent FILL material.

Log of Test Pit 12-4-TP-501

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1	Approximately 1 foot of organic debris (old logs and branches) over (medium dense), moist, light brown, very sandy GRAVEL.
S-2	3 to 6	4.5	1 to 7.5	(Medium dense to dense), moist, medium gray, slightly sandy GRAVEL with interbedded gravel layers with cobbles up to 10 inches.
S-3	8 to 10	4.5	7.5 to 9	(Very dense), moist, tan-brown, sandy GRAVEL.

Bottom of 12-4-TP-501 at 9 feet, completed 4/16/92.

Log of Test Pit 12-5-TP-501
Ground Surface Elevation Approximately 226.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6	One inch of grass over (medium dense), moist, dark brown, slightly silty, sandy GRAVEL with roots to a depth of 2 feet and minor debris (FILL) (see note below).
S-2	3 to 6	4.5		
			6 to 8	(Medium dense), moist, tan-brown, sandy GRAVEL (NATIVE).
S-3	8 to 10	4.5	8 to 10	(Medium dense), moist, light tan, sandy GRAVEL.

Bottom of 12-5-TP-501 at 10 feet, completed 4/16/92.

Note:
Chunks of compressed paper (cardboard) observed from depth of 5 to 6 feet.

Log of Test Pit 12-5-TP-502
Ground Surface Elevation Approximately 222.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 5.5	One inch of grass over (medium dense), moist, dark brown to black, slightly silty, very sandy GRAVEL with minor debris (FILL) (see note below).
S-2	3 to 5.5	4.5		
			5.5 to 7	(Medium dense), moist, medium gray, sandy GRAVEL (NATIVE).
S-3	8 to 10	4.5	7 to 10	(Medium dense), moist, light brown, slightly sandy GRAVEL (NATIVE).

Bottom of 12-5-TP-502 at 10 feet, completed 4/16/92.

Note:
Debris observed from depth of 2 to 4 feet: layers of compressed cardboard and plastic strapping.

Log of Test Pit 12-5-TP-503
Ground Surface Elevation Approximately 223.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 4	(Medium dense), moist, dark brown, silty, very sandy GRAVEL with debris (FILL) (see note below).
S-2	2 to 4	4.5		
S-3	4 to 6	5.0	4 to 10	(Medium dense), moist, brown, sandy GRAVEL with gravel layers.

Bottom of 12-5-TP-503 at 10 feet, completed 4/17/92.

Note:
Observed abundant decomposed cardboard explosives packaging from depth of 1 to 4 feet.

Log of Test Pit 12-6-TP-501
Ground Surface Elevation Approximately 225.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Medium dense), moist, dark brown, silty, sandy GRAVEL.
S-2	3 to 6	5	1.5 to 6.5	(Loose), moist, brown GRAVEL.
S-3	8 to 10	5	6.5 to 10	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 12-6-TP-501 at 10 feet, completed 4/17/92.

Log of Test Pit 12-6-TP-502
Ground Surface Elevation Approximately 225.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 8	(Medium dense), moist, dark brown, silty, sandy GRAVEL with debris (FILL) (see note below).
S-2	3 to 6	5		
S-3	8 to 10	5	8 to 10	(Medium dense), moist, medium brown, sandy GRAVEL (NATIVE).

Bottom of 12-6-TP-502 at 10 feet, completed 4/17/92.

Note:
Debris observed from depth of 3 to 8 feet: 1-inch-diameter plastic apparently empty white tubing, 1 car radio, assorted plastic debris, scattered bottles, jars and cans, and ceramics.

Log of Test Pit 12-7-TP-501

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.2	(Medium dense), moist, dark brown, silty, sandy GRAVEL.
S-2	3 to 6	5	1.2 to 10	(Loose), moist, brown, slightly sandy GRAVEL with gravel layers.
S-3	8 to 10	5		

Bottom of 12-7-TP-501 at 10 feet, completed 4/17/92.

Log of Test Pit 12-TP-501
Ground Surface Elevation Approximately 213.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 5.5	(Medium dense), moist to wet, black, slightly silty, very sandy GRAVEL with debris (FILL) (see Note 1 below). Zones of saturation (standing water) within fill below depth of 4.5 feet. Hydrogen sulfide odor associated with saturated zones.
S-2	3 to 4.5	4		
			5.5 to 9	(Dense), moist, dark brown, gravelly silty SAND (appears NATIVE). Soils more consolidated between 6 and 7 feet.
S-3	9 to 10	5	9 to 10	

Bottom of 12-TP-501 at 10 feet, completed 4/16/92.

Note:
Debris observed from depth of 0.5 to 6 feet: timbers, logs, plywood, and rolls of red paper (approximately 2 inches wide); pieces of styrofoam, cardboard, and plastic banding; scraps of cotton-like cloth with yellow powder-like substance (pH of 0 on pH paper).

Log of Test Pit 12-TP-502
Ground Surface Elevation Approximately 217.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2	(Medium dense), moist, black, slightly silty, very sandy GRAVEL with roots from 0 to 1 foot.
S-2	3 to 6	4	2 to 10	(Medium dense), moist, tan-brown, sandy GRAVEL with interbedded layers of gray, sandy gravel.
S-3	8 to 10	4		

Bottom of 12-TP-502 at 10 feet, completed 4/16/92.

Log of Test Pit 12-TP-503
Ground Surface Elevation Approximately 217.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Medium dense), moist, black, slightly silty, very sandy GRAVEL.
S-2	3 to 6	4.5	2 to 4	(Medium dense), moist, tan-brown, sandy GRAVEL.
S-3	4 to 10	4.5	4 to 10	(Medium dense), moist, medium gray, sandy GRAVEL with interbedded gravel layers.

Bottom of 12-TP-503 at 10 feet, completed 4/16/92.

Log of Test Pit 12-TP-504
Ground Surface Elevation Approximately 225.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.3	(Medium dense), moist, dark brown, silty, sandy GRAVEL.
S-2	3 to 6	5	1.3 to 7	(Loose), moist, brown GRAVEL.
S-3	8 to 10	5	7 to 10	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 12-TP-504 at 10 feet, completed 4/17/92.

Log of Test Pit 12-TP-505
Ground Surface Elevation Approximately 222.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 6	(Medium dense), moist, dark brown, silty, sandy GRAVEL with abundant debris (FILL) (see note below).
S-2	3 to 6	5		
S-3	8 to 10	5	6 to 10	(Dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 12-TP-505 at 10 feet, completed 4/17/92.

Note:
Debris observed from depth of 1.5 to 6 feet: abundant water gel bags, minor amounts of plastic banding, metal banding (strapping), 1-inch-diameter plastic pipe, plastic drum liners, and cardboard. Did not observe any residual water gel.

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 0.8	5	0 to 3	(Loose), moist, brown, gravelly SAND with thin layer of black material at depth of 1 foot (Sample S-1A).
S-1A	0.8 to 1	NM		
S-2	3 to 6	5	3 to 10	(Medium dense), moist, brown, gravelly SAND with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-517 at 10 feet, completed 5/14/92.

Log of Test Pit 18-TP-518

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Loose), moist, dark brown, sandy GRAVEL with abundant roots.
S-2	3 to 6	5	2.5 to 10	(Medium dense), moist, brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-518 at 10 feet, completed 5/14/92.

Log of Test Pit 18-TP-519

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Loose), moist, dark brown, gravelly SAND with minor organics and concrete debris.
S-2	3 to 6	5	2.5 to 10	(Dense), moist, brown, sandy GRAVEL with bedded gravel layers dipping southwest (NATIVE).
S-3	8 to 10	5		

Bottom of 18-TP-519 at 10 feet, completed 5/11/92.

Note:
Sample S-1 was a 4-point composite around debris (concrete, rebar) in center of Gelatin Mix House No. 3 foundation.

Log of Test Pit 18-TP-520

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), damp, brown, slightly gravelly, silty SAND with a small lens of black burnt wood from 1.3 to 1.5 feet, and bricks with pier block.
S-2	3 to 6	5	1.5 to 10	(Loose), damp, light brown, slightly sandy GRAVEL with gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-520 at 10 feet, completed 4/27/92.

Log of Test Pit 18-TP-521

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 10	(Loose), damp, brown, sandy GRAVEL with interbedded gravel layers.
S-2(R)	3 to 6	5		
S-3	8 to 10	5		

Bottom of 18-TP-521 at 10 feet, completed 5/12/92.

Note:
Sample S-1 is a 5-point composite from 0 to 1 foot in former Gelatin Mix House No. 1 foundation.

Log of Test Pit 18-TP-522

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 1	(Loose), damp, light brown, silty, gravelly SAND.
			1 to 2.5	(Loose), damp, dark brown, silty, gravelly SAND.
S-2(R)	3 to 6	5	2.5 to 10	(Loose), damp, brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-522 at 10 feet, completed 5/13/92.

Log of Test Pit 18-TP-523

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 8	(Medium dense), damp, medium and dark brown, silty, gravelly SAND with scattered pieces of burnt wood from 1 to 4 feet.
S-2	3 to 6	5		
S-3	8 to 10	5	8 to 10	(Medium dense), damp, light brown, sandy GRAVEL.

Bottom of 18-TP-523 at 10 feet, completed 5/13/92.

Log of Test Pit 18-TP-524

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), moist, dark brown, very gravelly SAND with roots.
S-2	3 to 6	5	1 to 10	(Medium dense), moist, brown, sandy GRAVEL with interbedded gravel layers (NATIVE).
S-3	8 to 10	5		

Bottom of 18-TP-524 at 10 feet, completed 5/12/92.

Log of Test Pit 18-TP-525

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 2	(Loose), moist, dark brown, gravelly SAND with roots and other organics.
			2 to 3.5	(Medium dense), moist, reddish brown, sandy GRAVEL with roots.
S-2	3 to 6	5	3 to 10	(Medium dense), moist, brown, sandy GRAVEL with gravel layers (NATIVE).
S-3	8 to 10	5		

Bottom of 18-TP-525 at 10 feet, completed 5/12/92.

Log of Test Pit 18-TP-526

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 3	(Loose), damp, dark brown, silty, sandy GRAVEL (see notes below).
S-2	3 to 6	4.5	3 to 10	(Medium dense), damp, light brown, sandy GRAVEL.
S-3	8 to 10	4.5		

Bottom of 18-TP-526 at 10 feet, completed 4/30/92.

Notes:

1) Sample S-1 is a five-point composite of soil from 0 to 1 foot in Gelatin Mix House No. 2 foundation. Soil had been disturbed by heavy equipment prior to sampling.
2) Observed a piece of wood from 0.5 to 1 foot in depth that appeared to be an old gutter or pipe.

Log of Test Pit 18-TP-527

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), damp, dark brown, silty, gravelly SAND.
S-2	3 to 6	5	2 to 10	(Medium dense), damp, light brown, slightly sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-527 at 10 feet, completed 5/13/92.

Note:
Surface disturbed by heavy equipment prior to excavation.

Log of Test Pit 18-TP-528

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 6	(Loose), damp, dark brown, silty, gravelly SAND (FILL?).
S-2	3 to 6	5		
S-3	8 to 10	5	6 to 10	(Medium dense), damp, light brown, sandy GRAVEL.

Bottom of 18-TP-528 at 10 feet, completed 5/13/92.

Log of Test Pit 18-TP-529

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), damp, dark brown, silty, gravelly SAND.
S-2	3 to 6	5	3 to 10	(Medium dense), damp, brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-529 at 10 feet, completed 5/13/92.

Log of Test Pit 18-TP-530

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Loose), damp, black, silty, gravelly SAND with large roots.
S-2	3 to 6	5	2.5 to 10	(Medium dense), damp, light brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-530 at 10 feet, completed 5/13/92.

Log of Test Pit 18-TP-531

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2.5	(Loose), damp, brown, silty, gravelly SAND with organics.
S-2	3 to 6	2.5 to 10	(Dense), damp, brown, sandy GRAVEL.
S-3	8 to 10		

Bottom of 18-TP-531 at 10 feet, completed 5/15/92.

Log of Test Pit 18-TP-532

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6	(Loose), damp, dark brown, silty, gravelly SAND (FILL)
S-2	3 to 6	4.5		
S-3	8 to 10	4.5	6 to 10	(Medium dense), damp, light brown, sandy GRAVEL (NATIVE).

Bottom of 18-TP-532 at 10 feet, completed 4/29/92.

Note:
Test pit excavated between 3 stem walls at Hall Packing House No. 4 foundation.

Log of Test Pit 18-TP-533

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2	(Loose), damp, brown, slightly gravelly, silty SAND.
S-2	2 to 3	5.0	2 to 3	(Dense), damp, gray, slightly gravelly, sandy SILT.
S-3	3 to 6	5	3 to 7.5	(Dense), damp, brown, silty, gravelly SAND with a thin layer of burnt wood (charcoal) at depth of 5 feet.
S-4	8 to 10	5	7.5 to 10	(Medium dense), damp, light brown, sandy GRAVEL.

Bottom of 18-TP-533 at 10 feet, completed 4/28/92.

Log of Test Pit 18-TP-534

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 3	(Loose), damp, dark and light brown, silty, gravelly SAND mixed with debris (FILL) (see note below).
S-2	3 to 6	4.5	3 to 10	(Loose), damp, light brown, sandy GRAVEL with gravel bedding (appears NATIVE).
S-3	8 to 10	4.5		

Bottom of 18-TP-534 at 10 feet, completed 4/30/92.

Note:
Debris observed from depth of 0 to 3 feet: wood debris, bricks, copper lines and potential asbestos-containing material (ACM). TLH Abatement Inc. removed potential ACM from excavation.

Log of Test Pit 18-TP-535

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), damp, light brown, sandy GRAVEL with bricks, metal fragments, and potential asbestos-containing material.
S-2	3 to 6	5	1.5 to 10	(Medium dense), damp, brown, sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 18-TP-535 at 10 feet, completed 4/27/92.

Note:
TLM Abatement Inc. removed potential asbestos-containing material from excavation.

Log of Test Pit 18-TP-536

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Medium dense), damp, reddish brown, slightly gravelly, silty SAND with scattered charcoal and bricks.
S-2	3 to 6	5	3 to 10	(Dense), moist, light brown, slightly sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 18-TP-536 at 10 feet, completed 4/27/92.

Log of Test Pit 18-TP-537

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Medium dense), damp, dark brown, silty, gravelly SAND.
S-2	3 to 6	5.5	2 to 8.5	(Loose), damp, light brown-gray, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	6	8.5 to 10	(Loose), damp, light brown-gray, gravelly SAND.

Bottom of 18-TP-537 at 10 feet, completed 4/24/92.

Log of Test Pit 18-TP-538

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5.5	0 to 0.5	(Medium dense), damp, brown, silty SAND with scattered bricks.
S-2	3 to 6	5.5	0.5 to 10	(Loose), damp, light brown-gray, slightly sandy GRAVEL and interbedded gravel layers.
S-3	8 to 10	5.5		

Bottom of 18-TP-538 at 10 feet, completed 4/24/92.

Note:
Brick pier pad observed at depth of 0 to 2.5 feet.

Log of Test Pit 18-TP-539

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), damp, brown, silty, gravelly SAND with scattered bricks.
			1 to 3	(Loose), damp, light brown-gray, sandy GRAVEL.
S-2	3 to 6	5	3 to 6	(Medium dense), damp, dark brown, silty, gravelly SAND.
S-3	8 to 10	5	6 to 10	(Loose), damp, light brown-gray, sandy GRAVEL.

Bottom of 18-TP-539 at 10 feet, completed 4/24/92.

Log of Test Pit 18-TP-540

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), damp, brown, silty, gravelly SAND with scattered bricks.
S-2	3 to 6	5	1 to 10	(Loose), damp, light brown-gray, slightly sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-540 at 10 feet, completed 4/24/92.

Note:
Brick pier pad observed from depth of 0 to 2.5 feet.

Log of Test Pit 18-TP-541

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	6	0 to 1.2	(Loose), damp, medium brown, silty, gravelly SAND with scattered bricks, organics, burnt wood, and metal debris.
S-2	3 to 6	5	1.2 to 10	(Medium dense), damp, light brown-gray, sandy GRAVEL with a discontinuous gravel lens from 6.5 to 9.5 feet.
S-3	8 to 10	5		

Bottom of 18-TP-541 at 10 feet, completed 4/24/92.

Log of Test Pit 18-TP-542

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2	(Loose), damp, dark brown, silty, sandy GRAVEL with scattered nails, charcoal, and other metal debris.
S-2	3 to 6	4.5	2 to 10	(Loose), damp, light brown, slightly sandy GRAVEL with gravel layers.
S-3	8 to 10	4.5		

Bottom of 18-TP-542 at 10 feet, completed 4/28/92.

Note:
Charcoal and metal debris observed on surface.

Log of Test Pit 18-TP-543

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), damp, medium brown, silty, gravelly SAND with scattered charcoal (to 0.7 foot) and nails.
S-2	3 to 6	5	1.5 to 10	(Loose), damp, light brown-gray, slightly sandy GRAVEL with interbedded gravel layers dipping west.
S-3	8 to 10	5		

Bottom of 18-TP-543 at 10 feet, completed 4/28/92.

Log of Test Pit 18-TP-544

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), damp, brown, slightly gravelly SAND.
S-2	3 to 6	5	1 to 6	(Medium dense), damp, medium brown, silty, sandy GRAVEL with debris (see notes below).
S-3	8 to 10	5	6 to 10	(Medium dense), damp, light brown, sandy GRAVEL.

Bottom of 18-TP-544 at 10 feet, completed 5/15/92.

Note:
Debris observed from depth of 1 to 4 feet: 1-inch-diameter steel pipe, steel ducts approximately 3 feet in diameter (crushed), wood fragments, and crystals of copper salts.

Log of Test Pit 18-TP-545

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 3	Three inches of forest duff over (loose), damp, medium brown, slightly gravelly, silty SAND.
S-2	3 to 6	4.5	3 to 6	(Loose), damp, dark brown, silty, sandy GRAVEL (see notes below).
S-3	8 to 10	4.5	6 to 10	(Medium dense), damp, light brown, slightly sandy GRAVEL.

Bottom of 18-TP-545 at 10 feet, completed 4/29/92.

Notes:

1) Found wire wrapped around treated wood, which appears to be part of a former pipeline, from depth of 2.5 to 5 feet.
2) Test pit excavated between two concrete "stem walls". Observed a small void beneath east stem wall.

Log of Test Pit 18-TP-546

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Medium dense), damp, medium brown, silty, gravelly SAND with a railroad tie and 1-inch-diameter metal pipe line near surface.
S-2	3 to 6	5	2 to 10	(Medium dense), damp, light brown, slightly sandy GRAVEL with gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-546 at 10 feet, completed 4/28/92.

Log of Test Pit 18-TP-547

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 0.5	(Loose), moist, dark brown, slightly silty, sandy GRAVEL (see note below).
S-2	3 to 6	5	0.5 to 10	(Medium dense), moist, tan-brown, sandy GRAVEL increasing in moisture with depth.
S-3	8 to 10	5		

Bottom of 18-TP-547 at 10 feet, completed 5/1/92.

Note:
Sample S-1 is a 5-point composite from depth of 0 to 1 foot.

Log of Test Pit 18-TP-548

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Loose), moist, dark brown, gravelly SAND with minor organics.
S-2	3 to 6	5	2.5 to 4	(Medium dense), moist, reddish brown, gravelly SAND.
S-3	8 to 10	5	4 to 10	(Medium dense), moist, brown, gravelly SAND with interbedded gravel layers.

Bottom of 18-TP-548 at 10 feet, completed 5/14/92.

Log of Test Pit 18-TP-549

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1	(Medium dense), moist, dark brown, slightly silty, sandy GRAVEL.
S-2	3 to 6	5	1 to 10	(Medium dense), moist, tan-brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 18-TP-549 at 10 feet, completed 5/1/92.

Note:
Sample S-1 is a 5-point composite from 0 to 1 foot within Dynamite Mix House No. 1 foundation.

Log of Test Pit 18-TP-550

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2.5	(Loose), damp, intermixed brown SAND; dark brown, sandy GRAVEL; and black, gravelly SAND with debris (FILL) (see note below).
S-2	3 to 6	2.5 to 7	(Dense), damp, medium brown, sandy GRAVEL (NATIVE).
S-3	8 to 10	7 to 10	(Medium dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of 18-TP-550 at 10 feet, completed 5/15/92.

Note:
Debris observed from depth of 0.5 to 2.5 feet: 2 timbers, 1 steel pipe, and pieces of sheet metal.

Log of Test Pit 18-TP-551

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	(Loose), damp, brown, silty, gravelly SAND with piece of plastic at 0.5 foot.
S-2	3 to 6	1.5 to 10	(Medium dense), moist, brown, sandy GRAVEL with gravel layers.
S-3	8 to 10		

Bottom of 18-TP-551 at 10 feet, completed 5/15/92.

Log of Test Pit 18-TP-552

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2	(Loose), damp, dark brown, silty, sandy GRAVEL with brick and mortar debris.
S-2	3 to 6	4.5	2 to 10	(Loose), damp, light brown, sandy GRAVEL with gravel layers.
S-3	8 to 10	4.5		

Bottom of 18-TP-552 at 10 feet, completed 4/29/92.

Log of Test Pit 18-TP-553

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6	(Loose), damp, dark brown, silty, gravelly SAND with debris and strong creosote odor (see notes below).
S-2	3 to 6	4.5		

Bottom of 18-TP-553 at 6 feet, completed 4/29/92.

Notes:

1) Debris found from depth of 1 to 6 feet: crushed sections of sheet metal ducting which appeared to be approximately 3 feet in diameter, creosote-treated wood debris, and short lengths of iron.
2) Potential asbestos-containing material (ACM) encountered throughout excavation; TLH Abatement Inc removed potential ACM.

Log of Test Pit 18-TP-554

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6	(Loose), damp, dark brown-black, silty, gravelly SAND with 1-inch diameter PVC waterline at 0.5 foot.
S-2	3 to 6	4.5		
			6 to 8	(Loose), damp, light brown, gravelly SAND.
S-3	8 to 10	5	8 to 10	(Medium dense), damp, light brown-gray, sandy GRAVEL.

Bottom of 18-TP-554 at 10 feet, completed 4/29/92

Log of Test Pit 18-TP-555

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 6.5	(Loose), damp, dark brown, silty, sandy GRAVEL mixed with debris (FILL) (see notes below).
S-2	3 to 6	5		
S-3	8 to 10	4.5	6.5 to 10	(Medium dense), moist, light-brown, sandy GRAVEL.

Bottom of 18-TP-555 at 10 feet, completed 4/30/92.

Note:

1) Debris mixed in with soils from 0 to 6.5 feet: moderate amount of bricks, mortar, creosote-treated wood, metal, and ash.
2) Observed thin layer of crystalline copper salts mixed with black SAND, in the side wall between depth of 3 and 4 feet.

Log of Test Pit 18-TP-556

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 10	(Loose), damp, light brown, slightly sandy GRAVEL with interbedded gravel layers.
S-2	3 to 6	5		
S-3	8 to 10	5		

Bottom of 18-TP-556 at 10 feet, completed 5/13/92.

Note:
1 to 2 feet of soil removed during interim source removal prior to test pit excavation.

Log of Test Pit 18-TP-557

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 10	(Loose), damp, medium gray SAND with debris (FILL) (see note below).
S-2	3 to 6	4.5		
S-3	8 to 10	4.5		

Bottom of 18-TP-557 at 10 feet, completed 4/30/92.

Note:
Debris observed from depth of 0 to 10 feet: abundant chunks of wood debris (mostly creosote-treated wood), lengths of iron, and charcoal.

Log of Test Pit 18-TP-558

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1.7	(Loose), damp, dark brown, silty, gravelly SAND mixed with wood fragments, lengths of iron, and scrap sheet metal (FILL).
S-2	1 to 2	4.5	1.7 to 2	(Loose), damp, black, silty SAND mixed with crystals of copper salts (FILL).
			2 to 3	(Loose), damp, dark brown, silty, gravelly SAND.
S-3	3 to 6	4.5	3 to 10	(Loose), damp, light brown, sandy GRAVEL.
S-4	8 to 10	4.5		

Bottom of 18-TP-558 at 10 feet, completed 4/30/92

Log of Test Pit 18-TP-559

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), moist, medium brown, sandy GRAVEL.
S-2	3 to 6	5	1 to 9	(Loose), moist, medium gray, sandy GRAVEL with (medium dense), tan-brown GRAVEL lenses at depths of 5 and 6 feet.
S-3	8 to 10	5	9 to 10	(Medium dense), moist, tan-brown, sandy GRAVEL.

Bottom of 18-TP-559 at 10 feet, completed 5/1/92.

Note: S-1 is a 5-point composite from 0 to 1 foot within the Biazzi-Nitrator foundation.

Log of Hand Auger Boring 18-HA-501

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2	(Medium dense), damp, dark brown, silty, sandy GRAVEL with minor organics.
S-2	2 to 3	2 to 3	(Dense), damp, light brown, sandy GRAVEL.

Bottom of 18-HA-501 at 3 feet, completed 5/21/92.

Log of Hand Auger Boring 18-HA-502

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Medium dense), damp, brown, silty, gravelly SAND.
S-2	2 to 3		

Bottom of 18-HA-502 at 3 feet, completed 5/21/92.

Log of Hand Auger Boring 18-HA-503

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Dense), damp, dark brown, silty, gravelly SAND with minor organics and charcoal.
S-2	2 to 3		

Bottom of 18-HA-503 at 3 feet, completed 5/21/92.

Log of Test Pit 18-TP-600

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	3-6	0 to 1	(Medium dense), moist, dark brown, slightly silty, sandy GRAVEL.
S-2	8-10	1 to 10	(Medium dense), moist, brown, sandy to slightly sandy GRAVEL.

Bottom of 18-TP-600 at 10 feet, completed 11/5/92

Note: Test pit excavated adjacent to observed surficial residual DNT.

Log of Test Pit 18-TP-601

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 2.5	(Medium dense), moist, dark brown, slightly silty, sandy GRAVEL with abundant organics.
S-2	3 to 6	2.5 to 10	(Medium dense), moist, brown, slightly sandy to sandy GRAVEL.
S-3	8 to 10		

Bottom of 18-TP-601 at 10 feet, completed 11/5/92.

Log of Test Pit 18-TP-602

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1	(Medium dense), moist, dark brown, sandy GRAVEL.
S-2	2 to 3	1 to 10	(Medium dense), moist, slightly sandy to sandy GRAVEL.
S-3	8 to 10		

Bottom of 18-TP-602 at 10 feet, completed 11/5/92.

Log of Test Pit 18-TP-603

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 0.75	(Medium dense), moist, dark brown, sandy GRAVEL (upper 3 to 4 inches have been graded and disturbed).
S-2	3 to 6	0.75 to 10	(Medium dense), moist, brown, slightly sandy to sandy GRAVEL.
S-3	8 to 10		

Bottom of 18-TP-603 at 10 feet, completed 11/5/92.

Note: Test pit excavated adjacent to observed surficial residual DNT.

Log of Test Pit 18-TP-604

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	3-6	0 to 1.5	(Medium dense), moist, dark brown, sandy GRAVEL with abundant organics.
S-2	8-10	1.5 to 10	(Medium dense), moist, brown, slightly sandy to sandy GRAVEL.

Bottom of 18-TP-604 at 10 feet, completed 11/5/92

Note: Test pit excavated adjacent to observed surficial residual DNT.

Figure A-18-36

Log of Test Pit 18-TR-101-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, gray, sandy GRAVEL.

Bottom of 18-TR-101-N at 4 feet, completed 6/28/93.

Log of Test Pit 18-TR-101-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-4	3-4	2-4	(Medium dense), moist, gray, sandy GRAVEL.

Bottom of 18-TR-101-S at 4 feet, completed 6/28/93.

Log of Test Pit 18-TR-102-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, dark brown TOPSOIL (FILL).
S-2	3-4	2-4	(Medium dense), moist, brown to gray, slightly sandy GRAVEL with concrete and copper debris (FILL).

Log of Test Pit 18-TR-102-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0 to 2	(Loose), moist, brown TOPSOIL (FILL).
S-4	3-4	2-4	(Medium dense), moist, brown to gray, slightly sandy GRAVEL with intact concrete foundation.

Bottom of 18-TR-102-E at 4 feet, completed 6/28/93.

Log of Test Pit 18-TR-103-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0 to 2	(Medium dense), moist, brown, slightly sandy GRAVEL.
S-4	3-4	2-4	(Medium dense), moist, brown to gray, slightly sandy GRAVEL (appears NATIVE).

Bottom of 18-TR-103-S at 4 feet, completed 6/28/93.

Log of Test Pit 18-TR-104-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0 to 2	(Loose), moist, brown sandy GRAVEL.
S-2	3-4	2-4	(Medium dense), moist, light gray, sandy GRAVEL.

Bottom of 18-TR-104-W at 4 feet, completed 6/28/93.

Log of Test Pit 18-TR-104-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	1-2	0-2	(Loose), moist, brown, sandy GRAVEL with broken pieces of concrete debris (FILL).
S-4	3-4	2-4	(Medium dense), moist, light gray sandy GRAVEL.

Note:
Bottom of 18-TR-104-E at 4 feet, completed 6/29/93.

Log of Test Pit 18-TR-105-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-3	(Loose), moist, brown, sandy GRAVEL with organics and concrete debris (FILL).
S-2	3-4	3-4	(Loose), moist, light brown, sandy GRAVEL.

Note:
Bottom of 18-TR-105-N at 4 feet, completed 6/29/93.

Log of Test Pit 18-TR-105-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-3	(Loose), moist, brown, sandy GRAVEL.
S-4	3-4	3-4	(Loose), moist, brown, sandy GRAVEL.

Bottom of 18-TR-105-S at 4 feet, completed 6/29/93.

Log of Test Pit 18-TR-106-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, dark brown TOPSOIL with organics, wood and steel debris (FILL).
S-2	3-4	2-4	(Medium dense), moist, brown, sandy GRAVEL.

Note:
Encountered a 6-inch cast iron water main, creosoted timbers, steel pipes, and cables at 1 foot depth. Bottom of 18-TR-106-W at 4 feet, completed 6/29/93.

Log of Test Pit 18-TR-106-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, dark brown TOPSOIL with organics, wood and steel debris (FILL).
S-4	3-4	2-4	(Medium dense), moist, brown, sandy GRAVEL.

Bottom of 18-TR-106-E at 4 feet, completed 6/29/93.

Log of Test Pit 18-TR-107-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, dark brown TOPSOIL with dark stained burned wood-charcoal (FILL).
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL with intermittent wood fragments (FILL).

Bottom of 18-TR-107-N at 4 feet, completed 6/29/93.

Log of Test Pit 18-TR-107-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, dark brown TOPSOIL with steel, copper, concrete, and plastic debris (FILL).
S-4	3-4	2-4	(Loose), moist, light brown to gray, sandy GRAVEL.

Bottom of 18-TR-107-S at 4 feet, completed 6/29/93.

Log of Test Pit 18-TR-108-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown TOPSOIL with concrete debris (FILL).
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL with wood fragments (FILL).

Note:
Bottom of 18-TR-108-E at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-108-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL with burned wood layer (FILL).
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-108-W at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-109-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown TOPSOIL.
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-109-W at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-109-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL with burned wood layer (FILL).
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-109-E at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-110-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown TOPSOIL with abundant organics.
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-110-N at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-110-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL with organics.
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-110-S at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-111-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-1.5	(Loose), moist, brown TOPSOIL with copper material (FILL).
S-2	3-4	1.5-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-111-E at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-111-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-1.5	(Loose), moist, brown TOPSOIL with organic matter.
S-4	3-4	1.5-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-111-W at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-112-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown TOPSOIL with steel debris (FILL).
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-112-S at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-112-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL .
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-112-N at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-113-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-4	(Loose), moist, brown TOPSOIL with mixed debris (FILL).
S-2	3-4	0-4	(Loose), moist, light brown, TOPSOIL with mixed debris (FILL).

Bottom of 18-TR-113-W at 4 feet, completed 6/30/93.

Note: Brick, steel, ceramics, and cable debris along with 6-inch ceramic pipe leading from an adjacent structure was encountered.

Log of Test Pit 18-TR-113-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-4	(Very loose), moist, dark brown TOPSOIL with mixed debris (FILL).
S-4	3-4	0-4	(Loose), moist, dark brown TOPSOIL with mixed debris (FILL).

Note:
Brick, steel, ceramics, and cable debris along with 6-inch ceramic pipe leading from an adjacent structure was encountered. Bottom of 18-TR-113-N at 4 feet, completed 6/30/93.

Log of Test Pit 18-TR-114-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL with abundant organics.
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-114-W at 4 feet, completed 7/1/93.

Log of Test Pit 18-TR-115-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown TOPSOIL.
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-115-N at 4 feet, completed 7/1/93.

Log of Test Pit 18-TR-115-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL.
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-115-S at 4 feet, completed 7/1/93.

Log of Test Pit 18-TR-116-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown TOPSOIL.
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL with patches of gravelly SAND.

Bottom of 18-TR-116-E at 4 feet, completed 7/1/93.

Log of Test Pit 18-TR-116-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL.
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL with patches of gravelly SAND.

Bottom of 18-TR-116-W at 4 feet, completed 7/1/93.

Log of Test Pit 18-TR-Depression

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-1.5	(Medium dense), moist, light brown, sandy GRAVEL.
S-2	3-4	1.5-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-Depression at 4 feet, completed 7/7/93.

Log of Test Pit 18-TR-117-W

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	1-2	0-3	(Loose), wet, brown TOPSOIL mixed with concrete debris (FILL).
S-2	4-5	3-5	(Loose), wet, light brown, sandy GRAVEL.

Bottom of 18-TR-117-W at 5 feet, competed 7/2/93.

Log of Test Pit 18-TR-117-E

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-3	(Loose), wet, brown TOPSOIL.
S-4	3-4	3-5	(Loose), wet, light brown, sandy GRAVEL.

Bottom of 18-TR-117-E at 5 feet, completed 7/2/93.

Log of Test Pit 18-TR-118-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown SAND.
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-118-N at 4 feet, completed 7/2/93.

Log of Test Pit 18-TR-118-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, brown TOPSOIL.
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL with patches of gravelly SAND.

Bottom of 18-TR-118-S at 4 feet, completed 7/2/93.

Log of Test Pit 18-TR-119-N

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, light brown SAND.
S-2	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-119-N at 4 feet, completed 7/2/93.

Log of Test Pit 18-TR-119-S

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-3	0-1	0-2	(Loose), moist, light brown SAND with burned wood layer (FILL).
S-4	3-4	2-4	(Loose), moist, light brown, sandy GRAVEL.

Bottom of 18-TR-119-S at 4 feet, completed 7/2/93.

TEST PITS PERFORMED AT GRID SAMPLE LOCATIONS

Log of Test Pit 18-TP-GS-16

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	1-2	0-2	(Medium dense), dry, light brown, sandy GRAVEL with organics.
S-2	3-4	2-4	(Medium dense), dry, light brown, sandy GRAVEL.

Note:
Undisturbed concrete occupied the 0 to 1 foot interval (transport angel walks). Bottom of 18-TP-GS-16 at 4 feet, completed 7/7/93.

Log of Test Pit 18-TP-GS-17

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), dry, light brown, sandy GRAVEL with organics.
S-2	3-4	2-4	(Medium dense), dry, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-17 at 4 feet, completed 7/7/93.

Log of Test Pit 18-TP-GS-22

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), dry, light brown, sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), dry, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-17 at 4 feet, completed 7/7/93.

Log of Test Pit 18-TP-GS-23

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, silty, sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-23 at 4 feet, completed 7/7/93.

Log of Test Pit 18-TP-GS-24

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0-1	0-2	(Medium dense), moist, brown, silty, sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-24 at 4 feet, completed 7/7/93.

Log of Test Pit 18-TP-GS-25

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, silty, sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-25 at 4 feet, completed 7/7/93.

Log of Test Pit 18-TP-GS-27

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, brown, slightly gravelly SAND with abundant organics. Berm material.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Note: Material encountered during 0-2 foot interval was from berms placed around buildings.
Bottom of 18-TP-GS-27 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-28

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-28 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-32

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-32 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-33

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-33 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-38

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-3	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	3-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-38 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-40

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-40 at 4 feet, completed 7/7/93.

Log of Test Pit 18-TP-GS-41

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-41 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-42

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-42 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-43

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Medium dense), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 18-TP-GS-43 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-47

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-1	(Loose), moist, brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	1-4	(Loose), moist, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-47 at 4 feet, completed 7/12/93.

Log of Test Pit 18-TP-GS-49

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), dry, dark brown, slightly sandy GRAVEL with abundant organics.
S-2	3-4	2-4	(Loose), dry, light brown to light gray, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-49 at 4 feet, completed 7/12/93.

Log of Test Pit 18-TP-GS-53

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), dry, light brown, slightly sandy GRAVEL with organics.
S-2	3-4	2-4	(Medium dense), dry, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-53 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-54

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-1	(Loose), dry, light brown, slightly sandy GRAVEL with organics.
S-2	3-4	1-4	(Medium dense), dry, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-54 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-59

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, black to light brown, slightly sandy GRAVEL with organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-59 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-62

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), dry, light brown, slightly sandy GRAVEL with organics.
S-2	3-4	2-4	(Medium dense), dry, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-62 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-70

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-1.5	(Loose), dry, dark to light brown, slightly sandy GRAVEL with organics.
S-2	3-4	1.5-4	(Medium dense), dry, light brown, sandy GRAVEL with cobbles.

Note:
Sand content in gravel layer decreasing with depth.
Bottom of 18-TP-GS-70 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-72

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, dark brown, slightly sandy GRAVEL with organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL with cobbles.

Note:
Layer of gravel dipping from south to north.
Bottom of 18-TP-GS-72 at 4 feet, completed 7/6/93.

Log of Test Pit 18-TP-GS-81

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0-1	0-2	(Loose), moist, light brown, slightly sandy GRAVEL with organics.
S-2	3-4	2-4	(Medium dense), moist, light brown, sandy GRAVEL with cobbles.

Bottom of 18-TP-GS-81 at 4 feet, completed 7/6/93.

AREA 1234
EXPLORATION LOGS

Log of Test Pit 1234-TP-501

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.1	(Loose), moist, dark brown, gravelly SAND (abundant organics).
S-2	3 to 6.0	5	1.1 to 8.0	(Medium dense), moist, brown, very sandy GRAVEL (roots observed at a depth of 6 feet).
S-3	8 to 10	5	8 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL.

Bottom of 1234-TP-501 at 10 feet, completed 5/18/92.

Log of Test Pit 1234-TP-502

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 4	(Loose), moist, brown, gravelly SAND.
S-2	3 to 6	5	4 to 6	(Medium dense), moist, gray-brown, gravelly SAND.
S-3	8 to 10	5	6 to 10	(Medium dense), moist, gray-brown, gravelly SAND.

Bottom of 1234-TP-502 at 10 feet, completed 5/18/92.

Log of Test Pit 1234-TP-503

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Medium dense), moist, brown, sandy GRAVEL with some metal debris and roots (see Note 2).
			1.5 to 3	(Loose), moist, yellow-brown and gray SAND.
S-2	3 to 6	5	3 to 10	(Medium dense), moist, gray-brown and rusty-brown, sandy GRAVEL with minor tar-like substance between 3 and 4 feet (see Note 3).
S-3	8 to 10	5		

Bottom of 1234-TP-503 at 10 feet, completed 5/21/92.

Notes:
1) Test pit excavated in area that was graded over during interim source removal.
2) Observed traces of potential asbestos-containing material.
3) Observed tar-like substance, similar to that observed on the bottom of NG gutters.

Figure A-1234-2

Log of Test Pit 1234-TP-504

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), moist, brown, gravelly SAND with minor organics.
S-2	3 to 6	5	1 to 3.5	(Loose), moist, tan, slightly gravelly SAND.
S-3	8 to 10	5	3.5 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL with interbedded gravel layers.

Bottom of 1234-TP-504 at 10 feet, completed 5/19/92.

Note:
Observed "NG wash gutter" in test pit side wall from 1 to 2 feet in depth. 6 inches of gray sand observed directly below the gutter.

Log of Test Pit 1234-TP-505

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), dense, light brown, sandy GRAVEL.
S-2	3 to 6	5	1 to 6	(Medium dense), moist, brown, sandy GRAVEL with large concrete block, bricks, and large roots.
			6 to 8	(Medium dense), moist, brown, gravelly SAND.
S-3	8 to 10	5	8 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL (Native).

Bottom of 1234-TP-505 at 10 feet, completed 5/19/92.

Log of Test Pit 1234-TP-506

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), damp, light brown, sandy GRAVEL.
S-2	3 to 6	5	2 to 10	(Medium dense), moist, brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-506 at 10 feet, completed 5/20/92.

Log of Test Pit 1234-TP-507

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, reddish brown, gravelly SAND.
S-2	3 to 6	5	2 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-507 at 10 feet, completed 5/18/92.

Log of Test Pit 1234-TP-508

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), dense, tan, sandy GRAVEL with occasional roots.
S-2	3 to 6	5	3 to 6	(Medium dense), moist, brown, sandy GRAVEL with minor roots.
S-3	8 to 10	5	6 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL with interbedded gravel layers.

Bottom of 1234-TP-508 at 10 feet, completed 5/18/92.

Log of Test Pit 1234-TP-509

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), moist, brown, very sandy GRAVEL.
			1 to 2	(Medium dense), moist, gray-brown, sandy GRAVEL.
S-2	3 to 6	5	2 to 10	(Medium dense), moist, yellow-brown, slightly sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-509 at 10 feet, completed 5/21/92.

Log of Test Pit 1234-TP-510

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), moist, silty, gravelly SAND with a few bricks and roots.
S-2	3 to 6	5	1 to 10	(Medium dense), moist, yellow-brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-510 at 10 feet, completed 5/21/92.

Log of Test Pit 1234-TP-511

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Medium dense), moist, dark brown, very sandy GRAVEL with minor organics.
S-2	3 to 6	5	2 to 4	(Medium dense), moist, yellow-brown, sandy GRAVEL.
S-3	8 to 10	5	4 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL with interbedded gravel layers.

Bottom of 1234-TP-511 at 10 feet, completed 5/21/92.

Log of Test Pit 1234-TP-512

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), moist, dark brown, gravelly SAND with roots.
S-2	3 to 6	5	1 to 8	(Medium dense), moist, gray-brown, sandy GRAVEL with interbedded gravel layers and minor iron staining.
S-3	8 to 10	5	8 to 10	(Loose), moist, brown SAND.

Bottom of 1234-TP-512 at 10 feet, completed 5/19/92.

Log of Test Pit 1234-TP-513

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, light brown, gravelly SAND with pieces of ceramic tile (FILL).
S-2	3 to 6	5	2 to 10	(Medium dense), moist, yellow-brown sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-513 at 10 feet, completed 5/19/92.

Log of Test Pit 1234-TP-514

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.2	(Medium dense), damp, dark brown, silty, gravelly SAND.
S-2	3 to 6	5	1.2 to 10	(Loose), moist, light brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-514 at 10 feet, completed 5/19/92.

Log of Test Pit 1234-TP-515

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Medium dense), damp, dark brown, silty, gravelly SAND.
S-2	3 to 6	5	2 to 10	(Medium dense), moist, light brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-515 at 10 feet, completed 5/19/92.

Log of Test Pit 1234-TP-516

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), moist, dark brown, gravelly SAND with minor organics.
S-2	3 to 6	5	1.5 to 10	(Medium dense), moist, yellow-brown, sandy GRAVEL with alternating layers of yellow-brown and gray-brown sandy GRAVEL to a depth of 6 feet and yellow-brown, sandy GRAVEL below 6 feet.
S-3	8 to 10	5		

Bottom of 1234-TP-516 at 10 feet, completed 5/20/92.

Log of Test Pit 1234-TP-517

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), moist, dark brown, gravelly SAND with abundant roots.
S-2	3 to 6	5	3 to 10	(Medium dense), moist, yellow-brown, sandy GRAVEL with alternating layers of yellow-brown and gray-brown, sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 1234-TP-517 at 10 feet, completed 5/20/92.

Log of Test Pit 1234-TP-518

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Loose), moist, dark brown SAND with minor organics.
S-2	3 to 6	5	2.5 to 8.5	(Loose), moist, gray-brown SAND.
S-3	8 to 10	5	8.5 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL.

Bottom of 1234-TP-518 at 10 feet, completed 5/19/92.

Log of Test Pit 1234-TP-519

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, brown, gravelly SAND with large piece of wood from 0.5 to 2 feet.
S-2	3 to 6	5	2 to 10	(Medium dense), moist, brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-519 at 10 feet, completed 5/20/92.

Log of Test Pit 1234-TP-520

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), moist, reddish brown, very gravelly SAND.
			1 to 3	(Medium dense), moist, gray-brown, sandy GRAVEL.
S-2	3 to 6	5	3 to 10	(Medium dense), moist, gray-brown, slightly sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-520 at 10 feet, completed 5/18/92.

Log of Test Pit 1234-TP-521

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), moist, dark brown, gravelly SAND (FILL).
			1 to 2	(Medium dense), moist, light brown, sandy GRAVEL with 4-inch layer of burnt wood at 1 foot depth (FILL).
S-2	3 to 6	5	2 to 8	(Medium dense), moist, gray-brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5	8 to 10	(Dense), moist, gray-brown GRAVEL.

Bottom of 1234-TP-521 at 10 feet, completed 5/18/92.

Log of Test Pit 1234-TP-522

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), moist, dark brown, gravelly SAND with minor organics.
S-2	3 to 6	5	1.5 to 10	(Medium dense), moist, yellow-brown, sandy GRAVEL with alternating layers of yellow-brown and gray-brown, sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 1234-TP-522 at 10 feet, completed 5/20/92.

Log of Test Pit 1234-TP-523

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), moist, brown, gravelly SAND with minor organics.
S-2	3 to 6	5	1.5 to 8	(Medium dense), moist, gray-brown, slightly sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5	8 to 10.0	(Medium dense), wet, gray-brown, slightly sandy GRAVEL.

Bottom of 1234-TP-523 at 10 feet, completed 5/20/92.

Log of Test Pit 1234-TP-524

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), damp, brown, gravelly SAND.
S-2	3 to 6	5	1 to 10	(Medium dense), moist, light brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-524 at 10 feet, completed 5/18/92.

Note:
Test pit excavated in the bottom of a previous 4-foot-deep trench.

Log of Test Pit 1234-TP-525

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), moist, brown, sandy GRAVEL with minor organics.
S-2	3 to 6	5	1 to 8	(Medium dense), moist, gray-brown, slightly sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5	8 to 10	(Medium dense), wet, gray-brown, slightly sandy GRAVEL.

Bottom of 1234-TP-525 at 10 feet, completed 5/20/92.

Note:
Test pit excavated in bottom of a previous 4-foot-deep trench.

Log of Test Pit 1234-TP-526

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), dense, dark brown, silty, gravelly SAND.
S-2	3 to 6	5	1 to 10	(Dense), moist, yellow-brown, sandy GRAVEL with interbedded gravel layers.
S-3	8 to 10	5		

Bottom of 1234-TP-526 at 10 feet, completed 5/19/92.

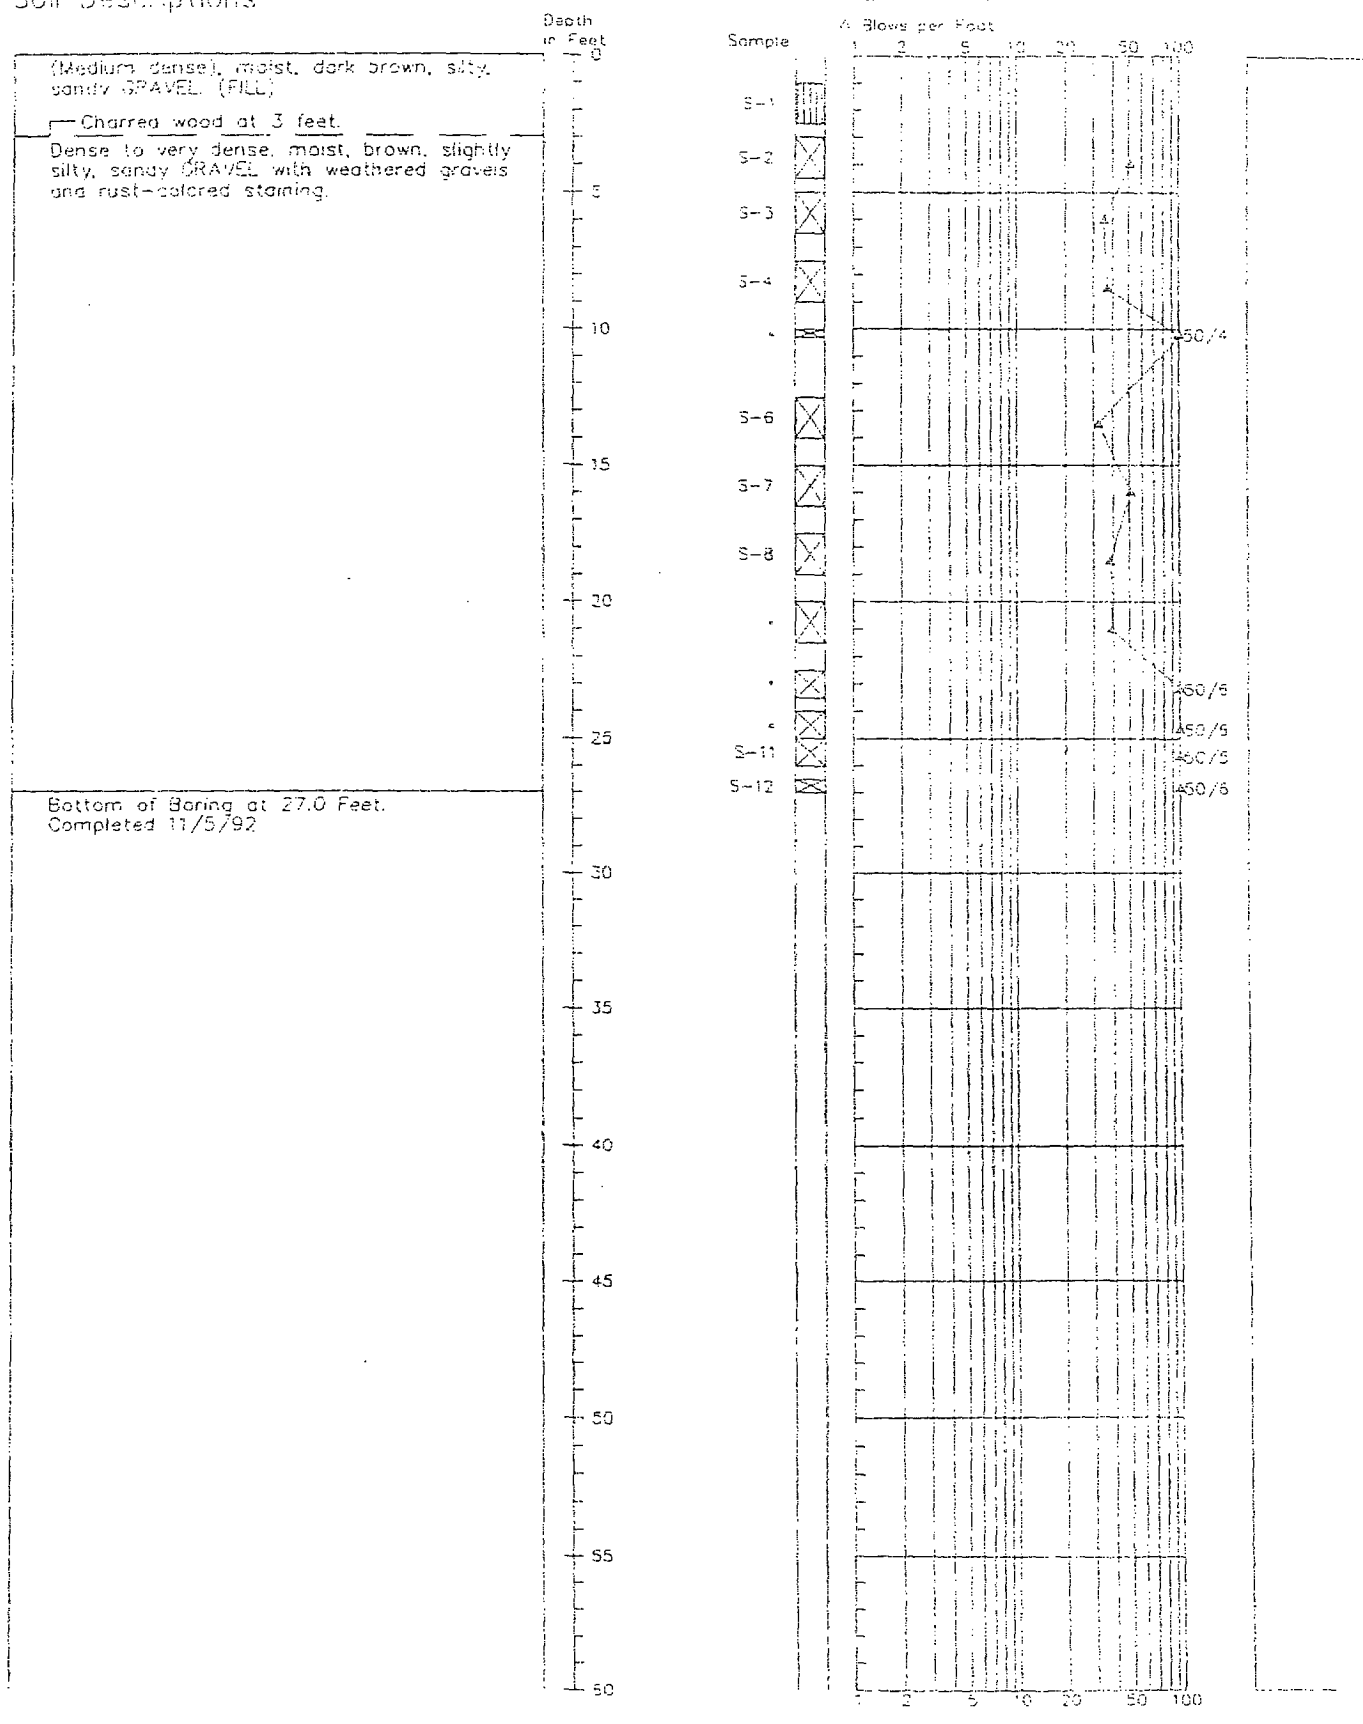
Log of Test Pit 1234-TP-527

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), moist, reddish brown, gravelly SAND with minor organics.
S-2	3 to 6	5	1.5 to 10	(Medium dense), moist, gray-brown, sandy GRAVEL with alternating layers of gray-brown and brown, sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 1234-TP-527 at 10 feet, completed 5/18/92.

AREA 25
EXPLORATION LOGS

Boring Log 25-B-501



1. *Refer to Figure A-1 for explanation of descriptions and symbols.*
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-25-1

Log of Test Pit 25-TP-501
Ground Surface Elevation Approximately 211.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 0.8	(Medium dense), moist, silver-gray, slightly sandy CRUSHED ROCK (FILL).
			0.8 to 3	(Medium dense), moist, medium brown, slightly silty, sandy GRAVEL (NATIVE).
S-2	3 to 6	5	3 to 10	(Medium dense), moist, tan-brown, sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 25-TP-501 at 10 feet, completed 4/22/92.

Log of Test Pit 25-TP-502
Ground Surface Elevation Approximately 211.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Medium dense), moist, medium brown, slightly silty, sandy GRAVEL with small roots in upper foot and a 2-inch layer of black, slightly silty, sandy gravel at 0.5 foot.
S-2	3 to 6	5	3 to 10	(Medium dense), moist, light brown, sandy GRAVEL with a 4-inch layer of very sandy gravel at 5 feet and abundant non-sandy gravel lenses.
S-3	8 to 10	5		

Bottom of 25-TP-502 at 10 feet, completed 4/22/91.

Log of Test Pit 25-TP-503
Ground Surface Elevation Approximately 209.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4	0 to 1	(Medium dense), moist, grayish black, silty, gravelly SAND with debris (FILL) (see Note 1 below).
S-2(R)	1 to 3	4	1 to 4	(Medium dense), moist, reddish brown, sandy GRAVEL.
			4 to 5	(Medium dense), moist, dark yellowish brown GRAVEL.
S-3	5 to 7	3.5	5 to 10	(Medium dense), moist, dark yellowish brown, sandy GRAVEL with interbedded silver-gray sandy gravel.
S-4	8 to 10	4		

Bottom of 25-TP-503 at 10 feet, completed 4/22/92.

Notes:
1) Debris observed from 0 to 1 foot included 2-inch-diameter lead pipe, 2-foot-long 4-inch-diameter steel pipe, and scattered bricks. 3.5- by 6-foot concrete slab at surface on northeast side of excavation. Bottom of slab was stained yellow.
2) Deteriorated gravels from depth of 1 to 10 feet.

Log of Test Pit 25-TP-504
Ground Surface Elevation Approximately 211.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	7	0 to 3	1-inch layer of silver-gray, sandy GRAVEL over (medium dense), moist, reddish brown, sandy GRAVEL.
S-2	3 to 6	6	3 to 10	(Medium dense), moist, medium gray, sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 25-TP-504 at 10 feet, completed 4/22/92.

Log of Test Pit 25-TP-505
Ground Surface Elevation Approximately 209.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 4	(Medium dense), moist, medium brown, slightly silty, sandy GRAVEL with small roots to depth of 1.5 feet (see note below).
S-2	3 to 6	5	4 to 10	(Dense), moist, medium gray, sandy GRAVEL interbedded with light brown, sandy gravel and some cobbles up to 12 inches in size.
S-3	8 to 10	5		

Bottom of 25-TP-505 at 10 feet, completed 4/22/92.

Note:
Observed a brick and cement wall between depths of 1.5 and 4 feet on the southwest wall of the excavation, with orange-brown soil adjacent to it.

Log of Test Pit 25-TP-506
Ground Surface Elevation Approximately 209.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2	2 inches of medium gray, slightly silty SAND over (medium dense), moist, medium brown, slightly silty, sandy GRAVEL with small roots.
S-2	3 to 6	5	2 to 10	(Medium dense), moist, light brown, sandy GRAVEL with interbedded layers of gravel and a 0.5-foot-thick layer of medium gray, very sandy gravel at 5.5 feet.
S-3	8 to 10	5		

Bottom of 25-TP-506 at 10 feet, completed 4/22/92.

Log of Test Pit 25-TP-507
Ground Surface Elevation Approximately 209.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4.5	0 to 3	(Medium dense), moist, medium brown, slightly silty, sandy GRAVEL with abundant small roots.
S-2	3 to 6	4.5	3 to 10	(Medium dense), moist, light brown, sandy GRAVEL with a lens of gravel from 5 to 7 feet.
S-3	8 to 10	4.5		

Bottom of 25-TP-507 at 10 feet, completed 4/23/92.

Log of Test Pit 25-TP-508
Ground Surface Elevation Approximately 208.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 3	(Medium dense), moist, mottled red-brown, medium brown, and medium gray, slightly silty, sandy GRAVEL.
S-2	3 to 6	5	3 to 10	(Medium dense), moist, medium gray, sandy GRAVEL with scattered cobbles and interbedded layers of gravel.
S-3	8 to 10	5		

Bottom of 25-TP-508 at 10 feet, completed 4/23/92.

Log of Test Pit 25-TP-509
Ground Surface Elevation Approximately 205.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 10	Weathered GRAVEL on surface over (medium dense), moist, light grayish brown, sandy GRAVEL with scattered areas of darker yellow staining and interbedded gravel layers.
S-2	3 to 6	4.5		
S-3	8 to 10	4.5		

Bottom of 25-TP-509 at 10 feet, completed 4/23/92.

Log of Test Pit 25-TP-510
Ground Surface Elevation Approximately 212.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Medium dense), moist, black, slightly silty, sandy GRAVEL.
S-2	3 to 6	4.5	1.5 to 4.5	(Medium dense), moist, tan-brown, sandy GRAVEL with a few interbedded gravel layers.
S-3	8 to 10	4.5	4.5 to 10	(Medium dense), moist, medium gray, sandy GRAVEL with interbedded gravel layers.

Bottom of 25-TP-510 at 10 feet, completed 4/23/92.

Log of Test Pit 25-TP-511
Ground Surface Elevation Approximately 201.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2	(Medium dense), moist, grayish black, slightly silty, sandy GRAVEL.
			2 to 3	(Medium dense), moist, reddish brown, slightly silty, sandy GRAVEL.
S-2	3 to 6	4	3 to 8	(Medium dense), moist, orange-brown, gray, tan-brown, and black (interlayered), slightly gravelly, silty SAND.
S-3	8 to 10	4	8 to 10	(Medium dense), moist, reddish brown and tan-brown, sandy GRAVEL.

Bottom of 25-TP-511 at 10 feet, completed 4/23/92.

Log of Test Pit 25-TP-512
Ground Surface Elevation Approximately 210.0 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 10	(Medium dense), moist, dark gray, sandy GRAVEL.
S-2	3 to 6		
S-3	8 to 10		

Bottom of 25-TP-512 at 10 feet, completed 11/4/92.

Note: Test pit excavated in area previously graded during interim source removal.

Log of Test Pit 25-TP-513
Ground Surface Elevation Approximately 208.3 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1.5	Three inches of grass over (medium dense), moist, dark brownish gray, slightly silty, sandy GRAVEL with weathered/deteriorated gravels.
S-2	3 to 6	1.5 to 4	(Medium dense), moist, to damp, reddish brown, sandy GRAVEL with scattered weathered gravels and minor rusty staining.
S-3	8 to 10	4 to 10	(Dense), damp, brown, slightly sandy to sandy GRAVEL.

Bottom of 25-TP-513 at 10 feet, completed 11/4/92.

Log of Test Pit 25-TP-514
Ground Surface Elevation Approximately 209.3 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1.75	Two inches of grass over (medium dense), moist, dark brownish gray, silty, sandy GRAVEL with deteriorated gravels (FILL?).
S-2	3 to 6	1.75 to 8	(Medium dense), damp, gray, silty, sandy GRAVEL with extremely deteriorated gravels.
S-3	8 to 10	8 to 12	(Dense), damp, gray, sandy GRAVEL with extremely deteriorated gravels.
S-4	12 to 14	12 to 14	(Dense), damp, brownish gray, sandy GRAVEL with bleached-looking gravels.

Bottom of 25-TP-514 at 14 feet, completed 11/4/92.

Note:
End of clay pipe visible at approximately 1-foot depth on north test pit wall. There was no evidence that the pipe extended through the test pit location.

Log of Test Pit 25-TP-515
Ground Surface Elevation Approximately 209.7 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1	Three inches of grass over (medium dense), moist, dark brown, sandy GRAVEL.
		1 to 2.5	(Medium dense), moist, brown, slightly sandy GRAVEL.
S-2	3 to 6	2.5 to 6	(Medium dense), moist, brown GRAVEL.

Bottom of 25-TP-515 at 7 feet, completed 11/3/92.

Note: Eight-inch-diameter steel water line encountered at 2.5 feet. Excavation stopped at 7 feet because digging in the collapsing gravels may have compromised the pipe.

Log of Test Pit 25-TP-516
Ground Surface Elevation Approximately 210.2 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1	Two inches of grass over (medium dense), moist, brown, sandy GRAVEL (FILL?).
S-2	1.5 to 3.5	1 to 3.5	(Medium dense), moist, dark gray, silty, sandy GRAVEL with deteriorated gravels.
S-3	4 to 6	3.5 to 10	(Dense), moist, brown, slightly sandy to non-sandy GRAVEL.
S-4	8 to 10		

Bottom of 25-TP-516 at 10 feet, completed 11/4/92.

Log of Test Pit 25-TP-517
Ground Surface Elevation Approximately 210.7 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 0.5	(Medium dense), moist, brown, sandy GRAVEL with minor brick fragments (FILL).
S-2	3 to 6	0.5 to 6	(Medium dense), moist, brown, non-sandy to slightly sandy GRAVEL.

Bottom of 25-TP-517 at 6 feet, completed 11/4/92.

Note: Excavation stopped at 6 feet due to collapsing of the excavation side walls.

Log of Test Pit 25-TP-518
Ground Surface Elevation Approximately 210.1 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 10	(Medium dense), moist, brown, sandy GRAVEL.
S-2	3 to 6		
S-3	8 to 10		

Bottom of 25-TP-518 at 10 feet, completed 11/4/92.

Log of Test Pit 25-TP-519
Ground Surface Elevation Approximately 210.4 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 0.5	(Medium dense), moist, dark brown, slightly sandy GRAVEL with minor lead debris.
S-2	3 to 6	0.5 to 7	(Medium dense), moist, brown, sandy GRAVEL.
S-3	8 to 10	7 to 10	(Dense), moist, brown, slightly sandy to non-sandy GRAVEL.

Bottom of 25-TP-519 at 10 feet, completed 11/4/92.

Log of Test Pit 25-TP-521
Ground Surface Elevation Approximately 210.6 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1.5	(Medium dense), moist, dark brown, sandy GRAVEL with abundant organics (roots).
		1.5 to 3	(Medium dense), moist, brown, sandy GRAVEL with minor rust-colored staining.
S-2(R)	3 to 6	3 to 4.5	(Medium dense), moist, grayish brown, sandy to slightly sandy GRAVEL with minor sand interbeds.
S-3(R)	8 to 10	4.5 to 10	(Medium dense), moist, brown, sandy to slightly sandy GRAVEL with minor sand interbeds.

Bottom of 25-TP-521 at 10 feet, completed 11/2/92.

Log of Test Pit 25-TP-522
Ground Surface Elevation Approximately 212.1 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 3.5	(Medium dense), moist, dark brown, sandy GRAVEL with abundant organics (roots).
S-2(R)	3 to 6	3.5 to 10	(Medium dense), moist to damp, brown, sandy GRAVEL with abundant sand interbeds.
S-3(R)	8 to 10		

Bottom of 25-TP-522 at 10 feet, completed 11/2/92.

Log of Test Pit 25-TP-523
Ground Surface Elevation Approximately 211.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1.5	(Dense), moist, dark brown, slightly silty, sandy GRAVEL with abundant organics (roots).
		1.5 to 3	(Dense), moist, light brown, sandy GRAVEL with minor rust-colored staining and roots to a depth of 2.5 feet.
S-2(R)	3 to 6	3 to 10	(Very dense), moist, brownish gray, slightly sandy to sandy GRAVEL with sand interbeds.
S-3(R)	8 to 10		

Bottom of 25-TP-523 at 10 feet, completed 11/2/92.

Log of Test Pit 25-TP-524
Ground Surface Elevation Approximately 213.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2	Three inches of forest duff over (dense), moist, brown, sandy GRAVEL (FILL?).
		2 to 3	(Dense), moist, dark brown, sandy GRAVEL with abundant roots.
S-2	3 to 6	3 to 10	(Dense), damp, brown, non-sandy to sandy GRAVEL with gravelly sand interbeds.
S-3	8 to 10		

Bottom of 25-TP-524 at 10 feet, completed 11/2/92.

Log of Test Pit 25-TP-525
Ground Surface Elevation Approximately 211.0 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1.5	Five inches of grass over (medium dense), moist, brown, sandy GRAVEL with noticeable "sweet" odor and minor organics.
S-2(R)	3 to 6	1.5 to 10	(Medium dense), moist, brown, gravelly SAND and sandy GRAVEL with strong "sweet" odor.
S-3(R)	8 to 10		

Bottom of 25-TP-525 at 10 feet, completed 11/2/92.

Figure A-26-3 2/2

Log of Test Pit 26-TP-501
Ground Surface Elevation Approximately 170.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), damp, dark gray, silty, gravelly SAND.
S-2	3 to 6	5	3 to 10	(Medium dense), damp to moist, brown, sandy GRAVEL with 6-inch-thick lens of iron-stained gravel at a depth of 3 feet.
S-3	8 to 10	5		

Bottom of 26-TP-501 at 10 feet, completed 3/23/92.

Log of Test Pit 26-TP-502
Ground Surface Elevation Approximately 174.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2.5	(Loose), damp, dark gray, silty, gravelly SAND with minor brick debris at surface.
S-2	3 to 6	4	2.5 to 10	(Medium dense), moist, gray and brown, silty, fine SAND. Sandy GRAVEL observed at a depth of 10 feet.
S-3	8 to 10	4		

Bottom of 26-TP-502 at 10 feet, completed 3/23/92.

Log of Test Pit 26-TP-503
Ground Surface Elevation Approximately 169.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), damp, dark gray, silty, gravelly SAND.
S-2	3 to 6	5	1 to 10	(Medium dense), moist, brown, sandy GRAVEL with abundant thin non-sandy gravel lenses.
S-3	8 to 10	5		

Bottom of 26-TP-503 at 10 feet, completed 3/23/92.

Log of Test Pit 26-TP-504
Ground Surface Elevation Approximately 174.7

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Loose), damp, dark gray, silty, sandy GRAVEL.
			1.5 to 4	(Medium dense), damp, brown, sandy GRAVEL.
S-2	3 to 6	5.5	4 to 5.5	(Loose), moist, brown GRAVEL.
			5.5 to 8	(Dense), moist, brown SAND.
S-3	8 to 10	5	8 to 10	(Medium dense), moist, brown, sandy GRAVEL.

Bottom of 26-TP-504 at 10 feet, completed 3/23/92.

Log of Test Pit 26-TP-505
Ground Surface Elevation Approximately 182.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	6	0 to 2	(Loose), damp, dark gray, silty, gravelly SAND.
S-2	3 to 6	5.5	2 to 4	(Medium dense), moist, brown, silty SAND.
S-3	8 to 10	6	4 to 10	(Medium dense), moist, brown, sandy GRAVEL.

Bottom of 26-TP-505 at 10 feet, completed 3/23/92.

Log of Test Pit 26-TP-506
Ground Surface Elevation Approximately 176.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), damp, dark gray, silty, gravelly SAND.
S-2	3 to 6	5	2 to 2.5	(Medium dense), damp, dark brown, sandy GRAVEL.
S-3	8 to 10	5	2.5 to 10	(Medium dense), moist, brown, sandy GRAVEL with lenses of slightly gravelly sand.

Bottom of 26-TP-506 at 10 feet, completed 3/24/92.

Log of Test Pit 26-TP-507
Ground Surface Elevation Approximately 172.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), damp, dark gray, silty, gravelly SAND with very thin zone of dark brown sand at a depth of 3 feet.
S-2	3 to 6	5.5	3 to 10	(Medium dense), moist, brown, sandy GRAVEL with interbedded non-sandy gravel lenses.
S-3	8 to 10	5		

Bottom of 26-TP-507 at 10 feet, completed 3/24/92.

Log of Test Pit 26-TP-508
Ground Surface Elevation Approximately 196.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 3	(Loose), damp, dark gray, silty, sandy GRAVEL with lead debris at surface and bricks to a depth of 3 feet (FILL).
S-2	3 to 6	5	3 to 4	(Medium dense), damp, brown, sandy GRAVEL, which thickens toward Unit 26-B kettle center (FILL).
			4 to 6	(Medium dense), damp, dark gray, silty, gravelly SAND with bricks (FILL).
S-3	8 to 10	4.5	6 to 10	(Dense), damp, brown, sandy GRAVEL.

Bottom of 26-TP-508 at 10 feet, completed 3/24/92.

Note:
Bricks were typically mortared together and appeared to have been pier blocks or footings for a former building.

Log of Test Pit 26-TP-509
Ground Surface Elevation Approximately 197.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 3.5	(Loose), damp, dark gray, silty, gravelly SAND with abundant roots. Grades to dark brown at a depth of 3 feet.
S-2	3 to 6	4.5	3.5 to 10	(Medium dense), damp, brown, very sandy GRAVEL with discontinuous lenses of gray, gravelly sand between depths of 7 and 7.5 feet.
S-4	7 to 7.5	4.5		
S-3	8 to 10	5		

Bottom of 26-TP-509 at 10 feet, completed 3/24/92.

Log of Test Pit 26-TP-510
Ground Surface Elevation Approximately 208.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), damp, dark gray, silty, sandy GRAVEL with bricks and bleached gravels at surface (FILL). Two lengths of 4-inch-diameter ceramic pipe (filled with soil) encountered between depths of 1 and 2 feet.
S-2	3 to 6	5	3 to 10	(Loose), damp, brown, slightly sandy GRAVEL with minor iron staining.
S-3	8 to 10	5		

Bottom of 26-TP-510 at 10 feet, completed 3/24/92.

Log of Test Pit 26-TP-511
Ground Surface Elevation Approximately 209.7 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	Blended rocks at surface over (loose), damp, dark gray and brown, silty, sandy GRAVEL with bricks, wood, and ceramic debris (FILL).
S-2	3 to 6	3 to 11	Twelve-inch-diameter ceramic pipeline overlying (dense), damp, gray, slightly sandy GRAVEL with indications of weathering. Distinct zone of yellow and brown staining observed immediately below pipeline extending to bottom of excavation.
S-2A	4 to 6		
S-3	8 to 10		

Bottom of 26-TP-511 at 11 feet, completed 3/25/92.

Notes:
1) S-2 is sample of unstained gray soil; S-2A and S-3 are samples of stained soil.
2) Ceramic pipeline slopes toward the south.

Log of Test Pit 26-TP-512
Ground Surface Elevation Approximately 211.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 3	(Loose), damp, dark gray, silty, sandy GRAVEL with concrete, brick, and wood debris (FILL). Three-inch-diameter lead pipe encountered at a depth of 1 foot.
S-2	3 to 6	5.5	3 to 10	(Medium dense), damp, brown, sandy GRAVEL.
S-3	8 to 10	5		

Bottom of 26-TP-512 at 10 feet, completed 3/25/92.

Note:
First two attempts to excavate within the former nitric acid recovery building foundation hit refusal when brick floor encountered. Location subsequently moved next to southwest corner of foundation.

Log of Test Pit 26-TP-513
Ground Surface Elevation Approximately 210.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Loose), damp, dark gray, silty, sandy GRAVEL with brick debris in upper 1.5 feet (FILL). Four-inch-diameter ceramic pipe observed along south side of excavation at depth of 2 to 3 feet. Small area of yellowish brown staining observed beneath pipe coupling.
S-2	3 to 6	4	2.5 to 10	(Medium dense), damp, brown, slightly sandy GRAVEL. Large area of yellowish brown staining from depths of 4 to 10 feet on west side of excavation away from observed ceramic pipe.
S-3	8 to 10	4		

Bottom of 26-TP-513 at 10 feet, completed 3/25/92.

Notes:
1) S-2 is sample of unstained soil; S-3 is sample of stained soil.
2) Ceramic pipe slopes toward the south.

Log of Test Pit 26-TP-514
Ground Surface Elevation Approximately 211.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet*	Soil Description
S-1	0 to 1	4	0 to (3 - 4)	(Loose), damp, dark gray, silty, sandy GRAVEL interbedded with gray SAND; brown, sandy GRAVEL; and purplish red, silty SAND (ash-like) and containing brick debris and deteriorated gravels. Lens of brownish yellow sandy gravel at depth of 1.5 to 2 feet.
S-3	3 to 6	4	(3 – 4) to 7	(Dense to very dense), damp, yellowish brown, slightly sandy GRAVEL.
S-4	6 to 7	4		

Bottom of 26-TP-514 at 7 feet, completed 3/25/92.

Notes:

1) Refusal at 7 feet due to cemented GRAVEL, which looked like native material but could not be penetrated by the backhoe.
2) Uneven contact between dark gray, silty, sandy GRAVEL and brownish yellow, sandy GRAVEL. Contact at 4 feet in center of pit, sloping up to 3 feet along the south and north sides. Range in depths across test pit indicated in parentheses.

Figure A-26-13

Log of Test Pit 26-TP-515
Ground Surface Elevation Approximately 211.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.25	(Loose), damp, dark brown, silty, gravelly SAND with occasional brick debris.
S-2	3 to 6	5	2.25 to 10	(Medium dense), damp, brown, slightly sandy GRAVEL.
S-3	8 to 10	5		

Bottom 26-TP-515 at 10 feet, completed 3/25/92.

Log of Test Pit 26-TP-516
Ground Surface Elevation Approximately 169.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1	(Loose), damp, dark gray, silty, gravelly SAND.
S-2	3 to 4	1 to 4	(Medium dense), moist, dark brown, slightly silty, sandy GRAVEL.
S-2A	4 to 6	4 to 10	(Medium dense), moist, brown, gravelly, silty SAND with organics and wood chips (becomes less silty and more gravelly with depth).
S-3	8 to 10		

Bottom of 26-TP-516 at 10 feet, completed 6/30/92.

Log of Test Pit 26-TP-517
Ground Surface Elevation Approximately 210.0 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1	(Loose), damp, tan, silty, sandy GRAVEL.
S-2	1 to 2	1 to 2	(Medium dense), damp, gray-brown and iron-stained, silty, sandy GRAVEL.
S-3	3 to 5	2 to 5	(Medium dense), moist, whitish gray and iron-stained, sandy GRAVEL.

Bottom of 26-TP-517 at 5.0 feet, completed 5/29/92.

Log of Test Pit 26-TP-518
Ground Surface Elevation Approximately 208.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2.5	(Loose), damp, gray-brown, silty, sandy GRAVEL with wood chunk (creosote odor) at depth of 2.5 feet.
S-2	1 to 2		
S-3	3 to 5	2.5 to 5	(Medium dense), damp, yellow brown and iron-stained, sandy GRAVEL.

Bottom of TP-518 at 5.0 feet, completed 6/29/92.

Log of Test Pit 26-TP-519
Ground Surface Elevation Approximately 210.7 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 5	(Medium dense), damp, light brown, silty, sandy GRAVEL with roots to depth of 4.5 feet.

Boring Log 31-B-503

Soil Descriptions

Ground Surface Elevation in Feet 215.1

(Loose), moist, black, silty, gravelly, fine to medium SAND.

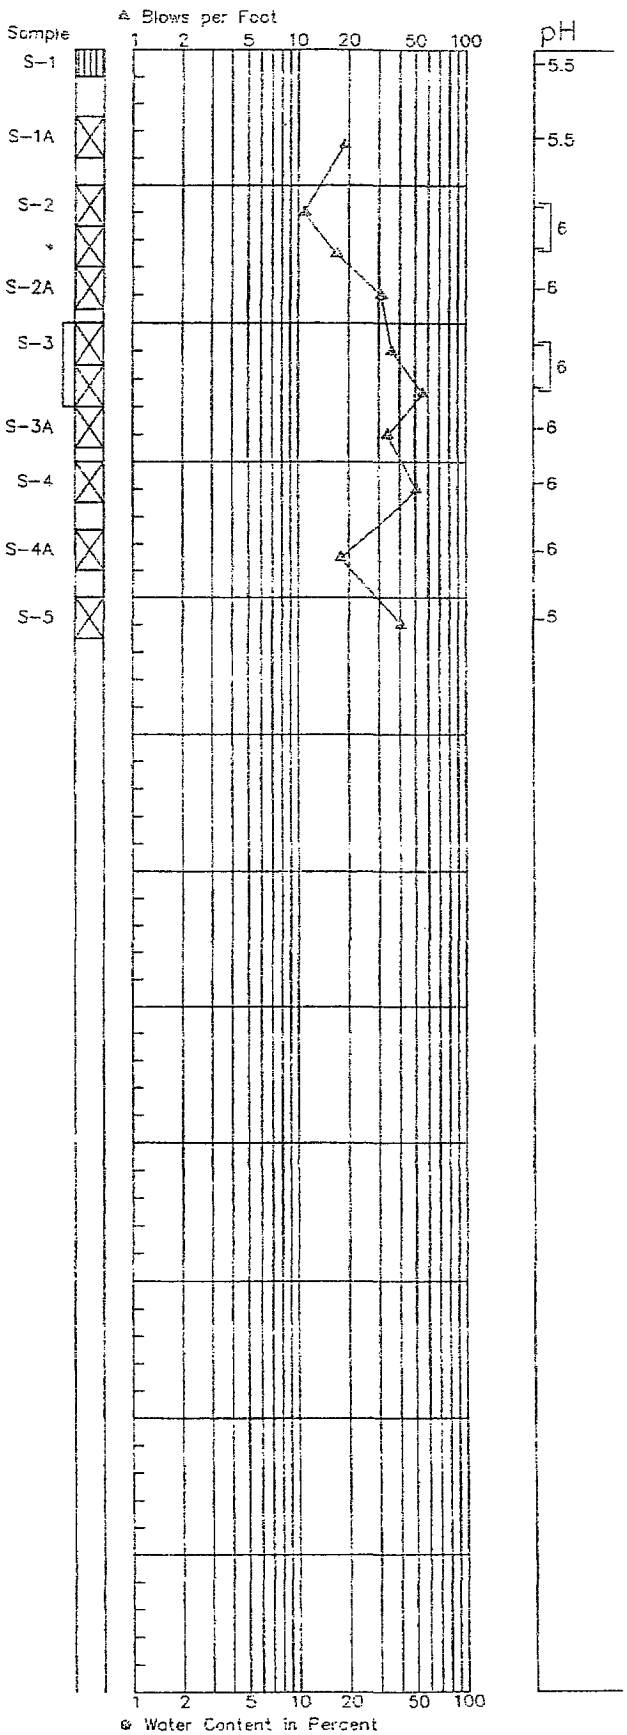
Medium dense to dense, moist, light brown, sandy GRAVEL.

Dense, moist, dark brown, very sandy gravel.

Medium dense to very dense, moist, light brown green, sandy GRAVEL.

Grades to wet, slightly sandy GRAVEL.

Bottom of Boring at 21.5 Feet.
Completed 2/19/92.



1. Refer to Figure A-1 for explanation of descriptions and symbols.
2. Soil descriptions and stratum lines are interpretive and actual changes may be gradual.
3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time.

Figure A-31-4 1/1

Log of Test Pit 31-TP-501
Ground Surface Elevation Approximately 212.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	4	0 to 0.8	(Medium dense), damp to moist, dark brown, silty, gravelly SAND with brick fragments, metal debris, burnt wood, and glass.
			0.8 to 2.1	(Dense), damp to moist, black, slightly silty, sandy GRAVEL with abundant roots and other organics.
S-2	3 to 6	6	2.1 to 10	(Dense), damp to moist, brown to tan, sandy GRAVEL.
S-3	8 to 10	6		

Bottom of 31-TP-501 at 10 feet, completed 2/26/92.

Log of Test Pit 31-TP-502
Ground Surface Elevation Approximately 215.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Medium dense), damp, black, silty, sandy GRAVEL with roots and debris (sardine cans).
S-2	3 to 6	5.5	2 to 4.5	(Dense), damp, tan-brown, slightly gravelly to gravelly SAND.
S-3	8 to 10	6.0	4.5 to 10	(Very dense), moist, tan to brown-gray, sandy GRAVEL with cobbles up to 6 inches in diameter. Soil becomes more moist and less dense, below 6 feet.

Bottom of 31-TP-502 at 10 feet, completed 2/26/92.

Log of Test Pit 31-TP-503
Ground Surface Elevation Approximately 210.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2	(Medium dense), moist, black, slightly gravelly, silty SAND with abundant roots.
S-2	3 to 6	5.5	2 to 4.5	(Medium dense), moist, tan-brown, very sandy GRAVEL.
S-3	8 to 10	5	4.5 to 10	(Dense), moist, tan-brown, sandy GRAVEL with cobbles up to 7 inches in diameter.

Bottom of 31-TP-503 at 10 feet, completed 2/27/92.

Log of Test Pit 31-TP-504
Ground Surface Elevation Approximately 212.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1.5	Grass over (medium dense), damp to moist, black, slightly gravelly, silty SAND with roots and other organics.
S-2	3 to 6	5	1.5 to 4	(Medium dense), moist, tan-brown, sandy GRAVEL with a lens of dark brown sand at depth of 2 feet.
S-3	8 to 10	5	4 to 10	(Medium dense), moist, brownish gray, sandy GRAVEL with cobbles up to 8 inches in diameter.

Bottom of 31-TP-504 at 10 feet, completed 2/26/92.

Log of Test Pit 31-TP-505
Ground Surface Elevation Approximately 214.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet*	Soil Description
S-1	0 to 1	4	0 to 2	(Medium dense), moist, black, sandy, silty GRAVEL with roots and an old log from depth of 0.5 to 1.5 feet.
S-2	3 to 6	5.5	2 to 7	(Medium dense), moist, tan-brown, sandy GRAVEL.
S-3	9 to 11	5.5	7 to 10.5	(Medium dense), moist, gray, gravelly SAND.
			10.5 to 11	(Medium dense), moist, orange-brown (iron-stained), slightly silty SAND with occasional roots.

Bottom of 31-TP-505 at 11 feet, completed 2/27/92.

Figure A-31-8

Log of Test Pit 31-TP-506
Ground Surface Elevation Approximately 211.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2	(Medium dense), moist, black, silty, sandy GRAVEL with roots and trace organics.
S-2	3 to 6	5	2 to 4	(Medium dense), moist, tan-brown, sandy GRAVEL.
			4 to 4.8	(Medium dense), moist, tan-brown, gravelly SAND with roots.
S-3	8 to 10	5	4.8 to 10	(Dense), moist, gray, sandy GRAVEL with cobbles up to 6 inches in diameter.

Bottom of 31-TP-506 at 10 feet, completed 2/27/92.

Log of Test Pit 31-TP-507
Ground Surface Elevation Approximately 211.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2	(Medium dense), moist, black, silty, gravelly SAND with roots and chunks of old logs.
S-2	3 to 6	5.5	2 to 4.5	(Medium dense), moist, tan, sandy GRAVEL with minor root fragments.
S-3	8 to 10	5	4.5 to 10	(Medium dense to dense), moist, gray, sandy GRAVEL with cobbles up to 8 inches in diameter. Becomes more moist and less sandy below a depth of 7 feet.

Bottom of 31-TP-507 at 10 feet, completed 2/27/92.

Log of Test Pit 31-TP-508
Ground Surface Elevation Approximately 209.0 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 3	(Medium dense), moist, medium brown, slightly gravelly, silty SAND with abundant small roots.
S-2	3 to 6	3 to 8	6 inches of black, silty SAND over (medium dense) moist, gray, slightly sandy GRAVEL with large roots and glass fragments.
S-3	8 to 10	8 to 10	(Medium dense), damp, gray, slightly sandy GRAVEL.

Bottom of 31-TP-508 at 10 feet, completed 2/24/92.

Log of Test Pit 31-TP-509
Ground Surface Elevation Approximately 209.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Medium dense), moist, black, sandy, silty GRAVEL with roots and an old log from depth of 0.5 to 1.5 feet.
S-2	3 to 6	5.5	1.5 to 10	(Medium dense to dense), moist, brownish gray, sandy GRAVEL with cobbles to 7 inches and abundant thin lenses of fine gravel.
S-3	8 to 10	5		

Bottom of 31-TP-509 at 10 feet, completed 2/27/92.

Log of Hand Auger Boring 31-HA-501

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Medium dense), moist, dark brown to brown, slightly silty, sandy GRAVEL with organics in upper one foot.
S-2	2 to 3		

Bottom of 31-HA-501 at 3 feet, completed 11/3/92.

Log of Hand Auger Boring 31-HA-502

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Medium dense), moist, dark brown to brown, silty to slightly silty, sandy GRAVEL with minor organics.
S-2	2 to 3		

Bottom of 31-HA-502 at 3 feet, completed 11/3/92.

AREA 38
EXPLORATION LOGS

Boring Log 38-B-501

Soil Descriptions

Ground Surface Elevation in Feet 206.0

Drywell (open hole to 7 feet)

Medium dense, wet to moist, gray, slightly gravelly, very sandy SILT (fill) with sulfur-like odor.

Medium dense, moist to wet, brown, slightly silty, slightly sandy GRAVEL.

Dense, wet to moist, brown, slightly sandy GRAVEL

Medium dense, moist to wet, slightly silty, slightly sandy GRAVEL.

Bottom of Boring at 23.0 Feet.
Completed 3/25/92.

Note: Boring completed within 3-foot square drywell with wood-lined walls.

Depth in Feet: 0, 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60

3. Groundwater level, if indicated, is at time of drilling (ATD) or for date specified. Level may vary with time

Figure A-38-1 1/1

*Log of Test Pit 38-TP-501
Ground Surface Elevation Approximately 213.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 0.5	(Loose), damp, black, silty, sandy GRAVEL with red flakes of paint on surface.
S-2	2 to 4	5	0.5 to 6	(Loose), moist, gray and dark brown, silty, gravelly SAND with potential asbestos-containing material and debris (see notes below) inside of old trench (FILL). Adjacent to both sides of trench is (medium dense), moist, brown, sandy GRAVEL (NATIVE).
S-3	4 to 6	4.5		
S-4	6 to 8	5.5	6 to 8	(Medium dense), moist, gray, sandy GRAVEL.
S-5	8 to 10	5.5	8 to 10	(Dense), moist, brown, slightly silty GRAVEL

Bottom of 38-TP-501 at 10 feet, completed 4/21/92.

Notes:
1) Encountered potential asbestos-containing material from depth of 3 to 6 feet, which was removed by TLH Abatement, Inc.
2) An abandoned trench was filled in with soil from depth of 0 to 6 feet. The trench fill contained wood debris (old gutter?), copper wire, and a 3/4-inch-diameter water line.

Log of Hand Auger Boring 38-HA-502

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Medium dense), moist, dark brown, silty, sandy GRAVEL with organics.

Ground Surface Elevation Approximately 212.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 5.5	3 inches of (dense), damp, dark brown, silty, sandy GRAVEL over (dense), damp, interbedded black and brown, silty, sandy GRAVEL (FILL).
S-2	1 to 2	4		
S-3	2 to 3	4		
S-4	3 to 5	4	5.5 to 6	(Medium dense), damp, brown, sandy GRAVEL (NATIVE).

Bottom of 40-CR-TP-503 at 6 feet, completed 4/3/92.

Note:
Test pit located on abandoned railroad grade.

Log of Test Pit 40-CR-TP-504
Ground Surface Elevation Approximately 211.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Loose), damp, black, silty, sandy GRAVEL.
S-2	1 to 2	5	1 to 2	(Medium dense), damp, brown, silty, sandy GRAVEL.
S-3	2 to 3	5	2 to 5	(Medium dense), damp, light brown, sandy GRAVEL.
S-4	3 to 5	5		

Bottom of 40-CR-TP-504 at 5 feet, completed 4/3/92.

Log of Test Pit 40-CR-TP-505
Ground Surface Elevation Approximately 211.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2	(Loose), damp, black, silty, sandy GRAVEL.
S-2	1 to 2	4		
S-3	2 to 3	4	2 to 3	(Medium dense) damp, brown, silty, sandy GRAVEL.
S-4	3 to 5	5	3 to 5	(Medium dense), damp, light brown, sandy GRAVEL.

Bottom of 40-CR-TP-505 at 5 feet, completed 4/3/92

Log of Test Pit 40-CR-TP-506
Ground Surface Elevation Approximately 210.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Medium dense), damp, black, silty, sandy GRAVEL.
S-2	1 to 2	5		
S-3	2 to 3	5	2 to 3	(Medium dense), damp, dark brown, silty, sandy GRAVEL.
S-4	3 to 5	6	3 to 6.5	(Loose), damp, light brown GRAVEL.
S-5	8 to 10	5	6.5 to 10	(Loose), damp dark gray, slightly sandy GRAVEL with boulders.

Bottom of 40-CR-TP-506 at 10 feet, completed 4/3/92

Note:
Abundant metal debris removed from surface prior to excavation.

Log of Test Pit 40-GM-TP-501

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 5	Six inches of dark brown TOPSOIL over (medium dense), moist, yellow-brown, slightly silty, sandy GRAVEL with gravel content increasing with depth. Standing water encountered at depth of 2.5 feet.
S-2	3 to 5	6		

Bottom of 40-GM-TP-501 at 5 feet, completed 2/18/92.

Note:
Test pit located in depression below site of former Glaze Mill No. 2.

Log of Test Pit 40-GM-TP-502

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	Six inches of dark brown, very organic TOPSOIL over (medium stiff), moist, yellow-brown, sandy SILT with iron staining and roots.
S-2	3 to 5	6	1 to 5	(Medium dense), moist to wet, yellow-brown, slightly silty, sandy GRAVEL with some boulders. Standing water encountered at depth of 3 feet.

Bottom of 40-GM-TP-502 at 5 feet, completed 2/18/92.

Note:
Water encountered at depth of 3 feet, could not bail out with backhoe.

Log of Test Pit 40-GM-TP-503
Ground Surface Elevation Approximately 198.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	6	0 to 1	(Loose), moist, dark brown, gravelly, very silty SAND with abundant roots and other organics.
			2.5 to 3	(Medium stiff), moist, yellow-brown, slightly gravelly, silty CLAY.
S-2	3 to 5	6	3 to 5	(Medium dense), moist to wet, yellow-brown, silty, sandy GRAVEL with gravel content increasing with depth. Water encountered at depth of 4 feet.

Bottom of 40-CR-TP-503 at 5 feet, completed 2/18/92

Note:
Rapid seepage of water encountered at depth of 4 feet.

Figure A-40-5

Log of Test Pit 40-GM-TP-504
Ground Surface Elevation Approximately 202.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	6	0 to 3	(Loose), damp, dark brown, silty, sandy GRAVEL with abundant organics (wood and roots).
S-2	3 to 5	5.5	3 to 7	(Medium dense), damp, yellow-brown, slightly silty, sandy GRAVEL with small roots.
S-3	5.5 to 6.5	6	7 to 10	(Medium dense), moist to wet, yellow-brown GRAVEL.

Bottom of 40-GM-TP-504 at 10 feet, completed 2/19/92.

Notes:
1) No standing water but GRAVEL was wet from depth of 9 to 10 feet.
2) Could not sample at depth of 8 to 10 feet because of sloughing of test pit walls.

Log of Test Pit 40-GM-TP-505
Ground Surface Elevation Approximately 215.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.8	(Loose), damp, dark brown, gravelly, very silty SAND with abundant roots.
S-2	3 to 5	6	1.8 to 5	(Medium dense), damp, yellow-brown, sandy GRAVEL with less sand content with depth and minor roots.

Bottom of 40-GM-TP-505 at 5 feet, completed 2/19/92

Log of Test Pit 40-GM-TP-506
Ground Surface Elevation Approximately 216.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5.5	0 to 2.5	(Loose), damp, dark brown, silty SAND with abundant roots (FILL?).
			2.5 to 3	(Medium dense), damp, yellow-brown, sandy GRAVEL (FILL?).
S-2	3 to 5	5.5	3 to 5	(Loose), damp, dark brown, gravelly, very silty SAND with roots.

Bottom of 40-GM-TP-506 at 5 feet, completed 2/19/92

Note:
Root horizons above and below depth of 3 feet suggests more than one fill episode.

Figure A-40-7

Log of Test Pit 40-GM-TP-507
Ground Surface Elevation Approximately 198.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), damp, dark brown, gravelly, very silty SAND with roots.
S-2	2.5 to 4.5	6	3 to 5	(Medium dense), moist to wet, yellow-brown, sandy GRAVEL. Water encountered at depth of 4.5 feet.

Bottom of 40-GM-TP-507 at 5 feet, completed 2/19/92.

Log of Test Pit 40-MH-TP-501
Ground Surface Elevation Approximately 214.6 Feet

S-3	2 to 3	4.5	2 to 3	(Medium dense), damp, gray, sandy GRAVEL.
S-4	3 to 5	5	3 to 5	(Medium dense), damp, brown, sandy GRAVEL.

Bottom of 40-MH-TP-507 at 5 feet, completed 4/2/92.

Log of Test Pit 40-MH-TP-508
Ground Surface Elevation Approximately 214.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), damp, dark brown, silty, very sandy GRAVEL.
S-2	1 to 2	5		
S-3	2 to 3	5	2 to 5	(Medium dense), damp, light brown, sandy GRAVEL.
S-4	3 to 5	5		

Bottom of 40-MH-TP-508 at 5 feet, completed 4/2/92

Log of Test Pit 40-PH-TP-501
Ground Surface Elevation Approximately 205.6 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2	(Loose), moist, dark brown, silty, gravelly SAND.
		2 to 3	(Medium dense), damp, greenish gray, sandy GRAVEL. Sand is primarily coarse-grained with little silt.
S-2	3 to 5	3 to 5	(Medium dense), damp, yellow-brown, slightly silty, sandy GRAVEL with minor roots.
		5 to 6	(Medium dense), damp, yellow-brown, gravelly SAND.
S-3	8 to 10	6 to 10	(Medium dense), moist to wet, yellow-brown, very sandy GRAVEL.

Bottom of 40 PH-TP-501 at 10 feet, completed 2/20/92

Log of Test Pit 40-PH-TP-502
Ground Surface Elevation Approximately 209.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2	(Loose), moist, dark brown, gravelly, silty SAND and organics.
S-2	3 to 5	2 to 5	(Medium dense), damp, yellow-brown, sandy GRAVEL with abundant rounded cobbles.

Bottom of 40-PH-TP-502 at 5 feet, completed 2/20/92.

Log of Test Pit 40-PH-TP-503
Ground Surface Elevation Approximately 210.9 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1.5	(Loose), moist, dark brown, gravelly, silty SAND with organics (roots).
S-2	3 to 5	1.5 to 5	(Medium dense), damp, yellow-brown, sandy GRAVEL with a few small roots.

Bottom of 40-PH-TP-503 at 5 feet, completed 2/20/92.

Log of Test Pit 40-PH-TP-504
Ground Surface Elevation Approximately 211.2 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	0 to 1.5	(Loose), moist, dark brown, gravelly, silty SAND with organics (roots).
S-2	3 to 5	1.5 to 5	(Medium dense), damp, yellow-brown, sandy GRAVEL with small roots.

Bottom of 40 PH-TP-504 at 5 feet, completed 2/20/92

Log of Test Pit 40-PH-TP-505
Ground Surface Elevation Approximately 211.6 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	(Loose), moist, dark brown, gravelly, silty SAND with organics (roots).
		1.5 to 3	(Medium dense), damp, yellow-brown, sandy GRAVEL with a 4-inch-thick lens of pea-size gravel at depth of 2.5 feet.
S-2	3 to 5	3 to 5	(Medium dense), damp, greenish gray, sandy GRAVEL.

Bottom of 40 PH-TP-505 at 5 feet, completed 2/20/92

Log of Test Pit 40-PR-TP-501
Ground Surface Elevation Approximately 211.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), damp, black, silty, very sandy GRAVEL with sand lenses and roots.
S-2	1 to 2	5	2 to 5	(Medium dense), damp, light brown, sandy GRAVEL.
S-3	2 to 3	5.5		
S-4	3 to 5	5.5		

Bottom of 40-PR-TP-501 at 5 feet, completed 4/1/92.

Log of Test Pit 40-PR-TP-502
Ground Surface Elevation Approximately 210.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 2	(Loose), damp, black, slightly gravelly, silty, fine SAND.
S-2	1 to 2	4		
S-3	2 to 3	4	2 to 3	(Loose), damp, brown, silty, fine SAND.
S-4	3 to 5	4.5	3 to 5	(Medium dense), damp, light brown, gravelly, medium to fine SAND.

Bottom of 40-PR-TP-502 at 5 feet, completed 4/1/92.

Log of Test Pit 40-PR-TP-503
Ground Surface Elevation Approximately 209.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	5	0 to 2	(Loose), damp, black, silty, sandy GRAVEL with roots.
S-2	1 to 2	5		
S-3	2 to 3	5.5	2 to 3	(Medium dense), damp, Dark brown, silty, sandy GRAVEL.
S-4	3 to 5	4.5	3 to 10	(Medium dense), damp, light brown, sandy GRAVEL.
S-5	8 to 10	4		

Bottom of 40-PR-TP-503 at 10 feet, completed 4/1/92

Log of Test Pit 40-PR-TP-504
Ground Surface Elevation Approximately 212.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), damp, silty, very sandy GRAVEL with roots.
S-2	1 to 2	5		
S-3	2 to 3	5	2 to 5	(Medium dense), damp, light brown, sandy GRAVEL.
S-4	3 to 5	5		

Bottom of 40-PR-TP-504 at 5 feet, completed 4/1/92

Log of Test Pit 40-PR-TP-505
Ground Surface Elevation Approximately 214.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 0.3	(Loose), damp, black, silty, sandy GRAVEL.
S-2	1 to 2	4	0.3 to 3.5	(Loose), damp, brown, sandy GRAVEL intermixed with black, silty, sandy GRAVEL.
S-3	2 to 3	4		
S-4	4 to 5	4	3.5 to 5	(Loose), damp, dark brown, silty, gravelly SAND (NATIVE).

Bottom of 40-PR-TP-505 at 5 feet, completed 4/1/92.

Note:
Test pit located on old railroad grade. The fill/native soil contacts were difficult to locate because of native soils used as fill in building the grade.

Log of Hand Auger Boring 40-PR-HA-501
Ground Surface Elevation Approximately 209.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
--	--	--	0 to 3.5	Empty, wood-lined drywell 3.5 feet deep by 4 feet wide.
S-1(R)	3.5 to 4	5	3.5 to 7.5	(Loose), moist, black, slightly gravelly, silty SAND with twigs and small pieces of wood. Numerous wood chunks, fir needles, and twigs from depth of 5 to 7 feet. A few weathered rocks at depth of 7 feet.
S-2(R)	4 to 4.5	4.5		
S-3(R)	4.5 to 5	4.5		
S-4(R)	5 to 5.5	4.5		
S-5(R)	5.5 to 6	4		
S-6(R)	6 to 6.5	4		
S-7(R)	6.5 to 7	4.5		
S-8(R)	7 to 7.5	3.5		
S-9(R)	7.5 to 8	3	7.5 to 8.3	(Loose), wet, black, slightly gravelly, silty SAND with residual petroleum, slight petroleum odor.
S-10(R)	8 to 8.3	3		
S-11(R)	8.3 to 9	1	8.3 to 9	(Loose), moist, silver-gray SAND.
S-12(R)	9 to 9.5	1	9 to 10.5	(Loose), moist, gold-yellow SAND.
S-13 (R)	9.5 to 10	1		
S-14(R)	10 to 10.5	1		

Bottom of 40-PR-HA-501 at 10.5 feet, completed 4/9/92

Note:
Hand Auger drilled in bottom of drywell.

Figure A-40-19

Log of Test Pit 40-PU-TP-501
Ground Surface Elevation Approximately 199.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1(R)	0 to 1	7	0 to 1	(Medium dense), moist, black, slightly silty, sandy GRAVEL with metal debris, old lumber, and apparent dried white paint.
S-2	1 to 1.5	6	1 to 2	(Medium dense), moist, orange-brown, sandy GRAVEL.
S-3	1.5 to 2	6		
S-4	2 to 2.5	6	2 to 3	(Medium dense), moist, tan-brown, medium sandy GRAVEL.
S-5	2.5 to 3	6		
S-6	3 to 5	6	3 to 4.5	(Medium dense), moist to wet, medium gray, coarse sandy GRAVEL.
S-7	8 to 10	6	4.5 to 10	(Medium dense), moist to wet, tan-brown, medium sandy GRAVEL with a few small gravel layers.

Bottom of 40-PU-TP-501 at 10 feet, completed 4/6/92.

Log of Test Pit 40-PU-TP-502
Ground Surface Elevation Approximately 195 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, medium brown, slightly silty, very gravelly SAND with abundant roots.
S-2	1 to 2	5		
S-3	2 to 3	5.5	2 to 3	.(Loose), moist, light brown, slightly silty, very gravely SAND with minor roots.
S-4	3 to 5	6	3 to 5	(Loose), moist, tan-brown, sandy GRAVEL.

Bottom of 40-PU-TP-502 at 5 feet, completed 4/6/92

Log of Test Pit 40-PU-TP-503
Ground Surface Elevation Approximately 205.9 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 5	(Loose), moist, dark brown, slightly silty, sandy GRAVEL with roots to a depth of 2.5 feet.
S-2	1 to 1.5	5		
S-3	1.5 to 2	5		
S-4	2 to 2.5	5		
S-5	2.5 to 3	5		
S-6	3 to 5	5		

Bottom of 40-PU-TP-503 at 5 feet, completed 4/6/92

Log of Test Pit 40-PU-TP-504
Ground Surface Elevation Approximately 208.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, dark brown, slightly silty, sandy GRAVEL with abundant roots.
S-2	1 to 2	5		
S-3	2 to 2.7	5	2 to 2.7	(Loose), moist, medium brown, sandy GRAVEL with occasional roots.
S-4	3 to 5	6	2.7 to 5	(Loose), moist, medium gray, sandy GRAVEL with areas of brown staining.

Bottom of 40-PU-TP-504 at 5 feet, completed 4/6/92.

Log of Test Pit 40-PU-TP-505
Ground Surface Elevation Approximately 209.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, dark brown to black, slightly silty, sandy GRAVEL with abundant roots.
S-2	1 to 2	5		
S-3	2 to 3	6	2 to 5	(Loose), moist, tan-brown, sandy GRAVEL.
S-4	3 to 5	6		

Bottom of 40-PU-TP-505 at 5 feet, completed 4/6/92.

Log of Test Pit 40-PU-TP-506
Ground Surface Elevation Approximately 197.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5.5	0 to 2	(Loose), moist, dark brown, slightly silty, sandy GRAVEL with broken glass from depth of 0 to 0.5 foot.
S-2	1 to 2	6		
S-3	2 to 3	6	2 to 4	(Loose), moist, light brown, sandy GRAVEL.
S-4	3 to 5	6	4 to 5	(Loose), moist, light gray-tan, very sandy GRAVEL.

Bottom of 40-PU-TP-506 at 5 feet, completed 4/6/92

Figure A-40-23

Log of Test Pit 40-WM1-TP-501
Ground Surface Elevation Approximately 207.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 0.5	(Medium dense), moist, black, silty, sandy GRAVEL with roots.
			0.5 to 2	(Medium dense), moist, tan-brown, sandy GRAVEL with roots.
S-2	3 to 5	5	2 to 6	(Medium dense to dense), moist, brownish gray, very sandy GRAVEL with 2 blocks of cement (1 foot square) at depth of 2 feet.
S-3	8 to 10	5	6 to 10	(Medium dense), moist, gray, gravelly SAND.
			10 to 10.5	(Medium dense to dense), moist, gray, sandy GRAVEL.

Bottom of 40-WM1-TP-501 at 10.5 feet, completed 2/28/92.

Notes:
1) Test pit excavated adjacent to foundation.
2) Bottom of foundation observed at depth of 7.5 feet.
3) Apparent fill material observed within approximately 2 feet away from foundation.

Log of Test Pit 40-WM1-TP-502
Ground Surface Elevation Approximately 208.3 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), moist, black, silty, sandy GRAVEL with roots and other organics.
			1 to 3	(Medium dense), moist, orange-brown, sandy GRAVEL with roots and gravel to 4 inches in diameter.
S-2	3 to 5	4.5	3 to 5	(Medium dense), moist, brownish gray, sandy GRAVEL.

Bottom of 40-WM1-TP-502 at 5 feet, completed 2/28/92

Log of Test Pit 40-WM1-TP-503
Ground Surface Elevation Approximately 206.8 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1.5	(Loose), damp, silty, very sandy GRAVEL with roots.
S-2	3 to 5	5	1.5 to 5	(Medium dense), moist, tan-gray, sandy GRAVEL.

Bottom of 40-WM1-TP-503 at 5 feet, completed 2/28/92

Log of Test Pit 40-WM1-TP-504
Ground Surface Elevation Approximately 205.6 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 2.5	(Medium dense), moist, black, silty, very sandy GRAVEL with roots and organic debris.
			2.5 to 3.5	(Medium dense to dense), moist, tan-brown, slightly sandy GRAVEL.
S-2	3 to 5	5.5	3.5 to 5	(Medium dense), moist, brownish gray, sandy GRAVEL.

Bottom of 40-WM1-TP-504 at 5 feet, completed 2/28/92.

Log of Test Pit 40-WM1-TP-505
Ground Surface Elevation Approximately 207.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1.5	(Medium dense), moist, dark brown to black, silty, sandy GRAVEL with abundant roots.
S-2	3 to 5	5.5	1.5 to 5	(Medium dense), moist, brownish gray, sandy GRAVEL with occasional roots.

Bottom of 40-WM1-TP-505 at 5 feet, completed 2/28/92.

Log of Hand Auger Boring 40-WM1-HA-501
Ground Surface Elevation Approximately 198.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5.5	0 to 0.5 (outside drywell)	(Loose),moist, black, slightly gravelly, silty SAND with roots.
			0 to 4	Empty, wood-lined drywell 4 feet deep by 1.5 feet wide by 3 feet long.
S-2	4 to 4.5	5	4 to 4.5	Forest Duff over (medium dense), moist, medium brown, sandy GRAVEL with layer of wood at depth of 4.3 feet (old wood floor?).
S-3(R)	4.5 to 5	5.5	4.5 to 5	(Medium soft), moist to wet, black, gravelly, very sandy SILT.
S-4(R)	5 to 5.5	5	5 to 5.5	(Medium dense), moist, medium brown, sandy GRAVEL.

Bottom of 40-WM1-HA-501 at 5.5 feet, completed 3/31/92

Notes:

1) Hand auger dug in abandoned drywell.
2) Sample S-1 collected from soil around edge of drywell opening. Samples S-2 through S-4 collected beneath bottom of drywell bottom (4 feet below grade).
3) Observed hollow steel pipe coming from Wheel Mill foundation and going into drywell.

Figure A-40-27

Log of Test Pit 40-WM2-TP-501
Ground Surface Elevation Approximately 206.5 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1(R)	5	0 to 1.2	(Loose), moist, black, gravelly, silty SAND with rusted scrap metal and wood (old roof?).
S-2	3 to 6	5	1.2 to 10	(Medium dense), moist, light brown, sandy GRAVEL with cobbles up to 4 inches in diameter.
S-3	8 to 9.5	5		

Bottom of 40-WM2-TP-501 at 9.5 feet, completed 3/2/92.

Log of Test Pit 40-WM2-TP-502
Ground Surface Elevation Approximately 205.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, black, silty, gravelly SAND with roots.
			2 to 3.5	(Medium dense), moist, dark brown, sandy GRAVEL.
S-3	3 to 5	5	3.5 to 5	(Medium dense), moist, light brown, sandy GRAVEL.

Bottom of 40-WM2-TP-502 at 5 feet, completed 3/2/92.

Log of Test Pit 40-WM2-TP-503
Ground Surface Elevation Approximately 210.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, black, silty, gravelly SAND with roots.
			2 to 3	(Medium dense), moist, dark brown, sandy GRAVEL.
S-2	3 to 5	5	3 to 5	(Dense), moist, light brown, sandy GRAVEL.

Bottom of 40-WM2-TP-503 at 5 feet, completed 3/2/92

Log of Test Pit 40-WM2-TP-504
Ground Surface Elevation Approximately 211.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.7	(Loose), moist, black, silty, gravelly SAND with tree roots and iron staining.
S-2	3 to 5	5.5	1.7 to 5	(Dense), moist, light brown, sandy GRAVEL with cobbles up to 6 inches in diameter.

Bottom of 40-WM2-TP-504 at 5 feet, completed 3/2/92

Log of Test Pit 40-WM2-TP-505
Ground Surface Elevation Approximately 211.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, black, silty, gravelly SAND with roots.
			2 to 2.5	(Medium dense), moist, dark brown, sandy GRAVEL.
S-2	3 to 5	5	2.5 to 5	(Dense), moist, light brown, sandy GRAVEL.

Bottom of 40-WM2-TP-505 at 5 feet, completed 3/2/92.

Log of Test Pit 40-WM2-TP-506
Ground Surface Elevation Approximately 210.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, black, silty, gravelly SAND with tree roots.
			2 to 3.5	(Medium dense), moist, dark brown, sandy GRAVEL.
S-2	3 to 5	5	3.5 to 5	(Dense), moist, light brown, sandy GRAVEL.

Bottom of 40-WM2-TP-506 at 5 feet, completed 3/2/92.

Log of Test Pit 40-WM2-TP-507
Ground Surface Elevation Approximately 205.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2	(Loose), moist, black, silty, gravelly SAND.
			2 to 2.5	(Medium dense), moist, dark brown, sandy GRAVEL.
S-3	3 to 5	5.5	2.5 to 5	(Dense), moist, light brown, sandy GRAVEL.

Bottom of 40-WM2-TP-507 at 5 feet, completed 3/2/92.

Note:
Test pit excavated next to old post. The black SAND (surficial soil) occurred as fill immediately surrounding the post to the depth of exploration.

Figure A-40-31

Log of Test Pit 40-WM3-TP-501
Ground Surface Elevation Approximately 208.0 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 4	(Loose), moist, black, silty, sandy GRAVEL (see notes below).
S-2	3 to 6	5	4 to 4.5	(Medium dense), moist, dark brown, sandy GRAVEL.
S-3	8 to 10	5	4.5 to 10	(Dense), moist, light brown, sandy GRAVEL with scattered debris (see notes below).

Bottom of 40-WM3-TP-501 at 10 feet, completed 3/3/92.

Notes:
1) Test pit excavated next to the foundation in what appeared to be an abandoned drywell.
2) Observed a small "void" by corner of test pit location (loose soils).
3) Debris from depth of 2.5 to 7 feet included 4-foot steel (brass) ground red; rusted, galvanized sheet metal; scattered wood chunks; vertical 2- by 6-inch planking from depths of 4 to 7 feet.
4) Encountered a 4-inch-diameter, hollow pipe, along side of foundation, which possibly lead to drywell.

Log of Test Pit 40-WM3-TP-501A

Sample Number	Stratum Depth in Feet	Soil Description
Not sampled	0 to 3	(Medium dense), moist, medium to dark brown, sandy GRAVEL with abundant roots (0 to 1 foot depth) with numerous chunks of cement debris up to 2 feet in length) (FILL).

Bottom of 40-WM3-TP-501A at 3 feet, completed 3/3/92

Notes:

1) Test pit abandoned due to cement slab at depth of 3 feet.
2) Moved test pit to new location (see 40-WM3-TP-501)

Figure A-40-33

Log of Test Pit 40-WM3-TP-502
Ground Surface Elevation Approximately 206.9 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1.5	2 inches of Forest Duff and branches over (medium dense to dense), moist, black, slightly sandy GRAVEL.
			1.5 to 4	A thin (<1 inch) layer of light orange-tan, gravelly SAND over (medium dense to dense), moist, medium brown, sandy GRAVEL.
S-2	3 to 5	5	4.0 to 5	(Medium dense), moist, light brown, very sandy GRAVEL.

Bottom of 40-WM3-TP-502 at 5 feet, completed 3/4/92.

Note:
Observed piece of rotten wood (post) from depth of 2.5 to 3 feet.

Log of Test Pit 40-WM3-TP-503
Ground Surface Elevation Approximately 209.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1	(Medium dense), moist, medium brown, sandy GRAVEL with roots.
			1 to 3.5	(Medium dense), moist, black, sandy GRAVEL.
S-2	3 to 5	5	3.5 to 5	(Medium dense), moist, light tan-brown, sandy GRAVEL.

Bottom of 40-WM3-TP-503 at 5 feet, completed 3/4/92

Log of Test Pit 40-WM3-TP-504
Ground Surface Elevation Approximately 209.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 2.5	(Loose), moist, black, silty, sandy GRAVEL.
S-2	3 to 5	5	2.5 to 5	(Dense), moist, light brown, sandy GRAVEL.

Bottom of 40-WM3-TP-504 at 5 feet, completed 3/3/92

Note:
Test pit excavated near abandoned railroad grade.

Log of Test Pit 40-WM3-TP-505
Ground Surface Elevation Approximately 213.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4	0 to 0.5	(Medium dense), moist, black, silty, very sandy GRAVEL.
			0.5 to 1.5	(Medium dense to dense), moist, tan- brown, sandy GRAVEL with 2 pieces of old wood.
S-2	3 to 5	4	1.5 to 5	(Medium dense to dense), moist, medium brown, sandy GRAVEL with occasional roots and cobbles.

Bottom of 40-WM3-TP-505 at 5 feet, completed 3/4/92.

Note:
Test pit excavated on former railroad grade.

Log of Test Pit 40-WM4-TP-501
Ground Surface Elevation Approximately 212.4 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 7	(Medium dense), moist, black, silty, sandy GRAVEL over (medium dense), moist, tan-brown, sandy GRAVEL.
S-2	3 to 6	5.5	7 to 7.5	(Loose), moist, medium gray, gravelly, medium to coarse SAND.
S-3	8 to 10	5.5	7.5 to 10	(Loose), moist, light yellowish-brown, coarse, sandy GRAVEL.

Bottom of 40-WM4-TP-501 at 10 feet, completed 3/16/92.

Log of Test Pit 40-WM4-TP-502
Ground Surface Elevation Approximately 213.2 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1.5	(Medium dense), moist, black, slightly silty, sandy GRAVEL with roots.
			1.5 to 3	(Medium dense), moist, tan-brown, sandy GRAVEL.
S-2	3 to 5	5.5	3 to 3.5	(Loose), moist, tan to gray, slightly gravelly, medium SAND.
			3.5 to 5	(Medium dense), moist, tan-brown, sandy GRAVEL.

Bottom of 40-WM4-TP-502 at 5 feet, completed 3/16/92

Log of Test Pit 40-WM4-TP-503
Ground Surface Elevation Approximately 214.1 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	4.5	0 to 1.5	(Medium dense), moist, black, slightly silty, sandy GRAVEL with roots.
			1.5 to 3	(Medium dense), moist, tan-brown, sandy GRAVEL.
S-2	3 to 5	5.5	3.5 to 4	(Medium dense), moist medium gray, gravelly, medium to coarse SAND.
			4 to 5	(Medium dense), moist, brownish gray, very sandy GRAVEL.

Bottom of 40-WM4-TP-503 at 5 feet, completed 3/16/92

Log of Test Pit 40-WM4-TP-504
Ground Surface Elevation Approximately 215.7 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 0.5	(Medium dense), moist, dark brown, slightly silty, sandy GRAVEL with minor roots.
			0.5 to 2.5	(Medium dense), moist, light tan-brown to dark brown, sandy GRAVEL.
S-2	3 to 5	4.5	2.5 to 4	(Medium dense), moist, dark brown-black, slightly silty, sandy GRAVEL.
			4 to 5	(Medium dense), moist, medium brown, sandy GRAVEL with area of iron staining at depth of 4 feet.

Bottom of 40-WM4-TP-504 at 5 feet, completed 3/16/92.

Log of Test Pit 40-WM4-TP-505
Ground Surface Elevation Approximately 212.9 Feet

Sample Number	Sample Depth in Feet	pH	Stratum Depth in Feet	Soil Description
S-1	0 to 1	5	0 to 1.5	(Medium dense), moist, black, slightly silty, sandy GRAVEL with abundant roots.
			1.5 to 2.5	(Medium dense), moist, tan-brown, sandy GRAVEL.
S-2	3 to 5	5.5	2.5 to 3.4	(Medium dense), moist, medium gray, gravelly, medium to coarse SAND.
			3.4 to 3.8	(Medium dense), moist, tan-brown, sandy GRAVEL.
			3.8 to 5	(Medium dense), moist, grayish brown, sandy GRAVEL with an 8-inch diameter cement drain pipe at depth of 4 feet.

Bottom of 40-WM4-TP-505 at 5 feet, completed 3/16/92

Figure A-40-39

Log of Observation Test Pit 40-OB-TP-501

Sample Number	Stratum Depth in Feet	Soil Description
Not Sampled	0 to 1	(Medium dense), moist, black, slightly silty, sandy GRAVEL with roots.
	1 to 3.5	(Medium dense), moist, tan-brown, sandy GRAVEL.

Bottom of 40-WM4-OB-TP-501 at 3.5 feet, completed 3/16/92.

Log of Test Pit 40-TP-600

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3.5	(Medium dense), moist, brownish gray, medium to fine SAND with scattered gravels and remnants of blasting wire (FILL).
S-2	4 to 6	3.5 to 10	(Medium dense), moist, dark brown to brown, sandy GRAVEL with occasional cobbles to 1 foot.
S-3	8 to 10		

Bottom of 40-TP-600 at 10 feet, completed 11/6/92.

AREAS OF POTENTIAL CONCERN
EXPLORATION LOGS

Log of Test Pit APA-TP-501
Ground Surface Elevation Approximately 204.5 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	(Loose), moist, brown, silty, sandy GRAVEL with minor organics.
		1.5 to 2.5	(Loose), moist, gray, pea-size GRAVEL.
S-2	3 to 5	2.5 to 5	(Medium dense), moist, yellowish brown, sandy GRAVEL.

Bottom of APA-TP-501 at 5 feet, completed 5/27/92.

Log of Test Pit APB-TP-501
Ground Surface Elevation Approximately 209.4 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 0.6	(Loose), damp, brown, silty, gravelly SAND with some roots
S-2	3 to 5	0.6 to 5	(Loose), damp, light brown, slightly sandy GRAVEL with interbedded gravelly, coarse sand lenses.

Bottom of APB-TP-501 at 5 feet, completed 5/27/92.

Log of Test Pit APB-TP-502
Ground Surface Elevation Approximately 202.7 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.4	(Loose), damp, brown, silty, sandy GRAVEL.
S-2	3 to 5	1.4 to 5	(Loose), damp, medium brown, sandy GRAVEL with interbedded gravel layers.

Bottom of APB-TP-502 at 5 feet, completed 5/27/92.

Log of Test Pit APC-TP-501
Ground Surface Elevation Approximately 209.8 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1	(Medium dense), moist, light brown, silty, sandy GRAVEL.
		1 to 2	(Loose), damp, gray, pea-size GRAVEL.
S-2	3 to 5	2 to 5	(Medium dense), moist, brown, sandy GRAVEL.

Bottom of APC-TP-501 at 5 feet, completed 5/26/92.

Log of Test Pit APC-TP-502

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.25	Two inches of Forest Duff over 2 inches of charred soil over (medium dense), moist, dark brown, slightly silty, sandy GRAVEL.
S-2	1 to 2	1.25 to 10	(Medium dense), moist, brown, slightly sandy to sandy GRAVEL with 6-inch layer of medium to fine SAND at 4 feet. Bleached-looking soils observed between depths of 1 to 7 feet along southeast wall of pit.
S-3	3 to 6		
S-4	8 to 10		

Bottom of APC-TP-502 at 10 feet, completed 11/3/92.

Log of Test Pit APC-TP-503

Stratum Depth in Feet	Soil Description
0 to 4	(Medium dense), damp, dark brown to brown, sandy GRAVEL.

Bottom of APC-TP-503 at 4 feet, completed 11/5/92.

Note: Approximately 30 x 18-foot observational test pit excavation. No samples collected because no evidence of potential "sump well" (as indicated from historical drawings) observed.

Log of Test Pit APD-TP-501
Ground Surface Elevation Approximately 210.1 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 3	(Loose), moist, dark brown, silty, sandy GRAVEL with abundant brick debris, quartz, and glazed tile chunks.
S-2	3 to 5	3 to 5	(Medium dense), moist, yellowish brown, sandy GRAVEL.

Bottom of APD-TP-501 at 5 feet, completed 5/27/92.

Notes:

1) APD-TP-501 excavated along a length of approximately 20 feet in attempt to locate remnants of the former Asphalt Paint Building (in an area of graded surficial soils). Although construction debris (e.g., bricks) was encountered, no foundations, pilings, or other evidence of a former building was observed.
2) Observed a few pieces of a tar-like substance (up to 4 inches long) and lead debris on surface.

Log of Test Pit APE-TP-501
Ground Surface Elevation Approximately 217.1 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2	Bricks and mortar over 2 inches of black, silty SAND over (medium dense), damp, brown, silty, gravelly SAND.
S-2	3 to 5	2 to 5	(Dense), moist, brown, sandy GRAVEL (NATIVE).

Bottom of APE-TP-501 at 5 feet, completed 5/26/92.

Log of Test Pit APE-TP-502

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	Two inches of sod over (medium dense), moist, brown, sandy GRAVEL with minor organics (FILL?).
S-2	1 to 2	1.5 to 5	(Medium dense), moist, brown, gravelly SAND.
S-3	3 to 5		

Bottom of APE-TP-502 at 5 feet, completed 11/3/92.

Note: Test pit excavated along edge of 6-inch-thick concrete slab (Main Transformer House foundation).

Log of Test Pit APF-TP-501

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2.5	(Loose), moist, dark brown, silty, gravelly SAND with minor organics.
S-2	3 to 5	2.5 to 5	(Medium dense), moist, yellowish brown, sandy GRAVEL.

Bottom of APF-TP-501 at 5 feet, completed 5/27/92.

Log of Hand Auger Boring APF-HA-501

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 2	(Medium dense), moist, dark brown, silty, sandy GRAVEL with abundant organics.
S-2	1 to 2		
S-3	2 to 3	2 to 3	(Medium dense), damp, brown, slightly silty, sandy GRAVEL.

Bottom of APF-HA-501 at 3 feet, completed 10/30/92.

Log of Test Pit APG-TP-501
Ground Surface Elevation Approximately 208.0 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	(Loose), moist, dark brown, silty, sandy GRAVEL with abundant roots and an old water line.
		1.5 to 3	(Loose), moist, gray, pea-size GRAVEL.
S-2	3 to 5	3 to 5	(Medium dense), moist, yellowish brown, sandy GRAVEL.

Bottom of APG-TP-501 at 5 feet, completed 5/26/92.

Log of Test Pit APG-TP-502
Ground Surface Elevation Approximately 209.0 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1	(Loose), moist, dark brown, silty, sandy GRAVEL with minor organics.
S-2	3 to 5	1 to 5	(Medium dense), moist, yellowish brown, sandy GRAVEL.

Bottom of APG-TP-502 at 5 feet, completed 5/26/92.

Log of Test Pit APG-TP-503
Ground Surface Elevation Approximately 211.0 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	(Loose), moist, brown, silty, sandy GRAVEL with minor organics.
		1.5 to 3	(Medium dense), moist, yellowish brown, sandy GRAVEL.
S-2	3 to 5	3 to 5	(Loose), moist, gray, pea-size GRAVEL.

Bottom of APG-TP-503 at 5 feet, completed 5/26/92.

Log of Test Pit APG-TP-504
Ground Surface Elevation Approximately 210.4 Feet

Sample Number	Sample Depth in Feet	Stratum Depth in Feet	Soil Description
S-1	0 to 1	0 to 1.5	(Loose), moist, brown, silty, sandy GRAVEL with minor organics and pieces of wire and rebar.
		1.5 to 3	(Loose), moist, gray, pea-size GRAVEL.
S-2	3 to 5	3 to 5	(Medium dense), moist, yellowish brown, sandy GRAVEL.

Bottom of APG-TP-504 at 5 feet, completed 5/27/92.

Appendix B presents soil quality data representing current Site conditions as of September 2001. The tables are organized and labeled according to area as discussed in Section 2. The tables are in the same order as that in which they are discussed in Section 2—Site Areas (by number), AP Areas, Site Reference Area (REF), and Narrow-Gauge Railroad (NGRR). Refer to Section 2 for a complete description of each Site Area. Specific notes for the tables are as follows:

1. Blanks indicate no analysis for a specific constituent.
2. Soil quality data representing Site conditions as of September 2001 are provided in the tables, including pre-RI, RI, and interim source removal verification sampling results.
3. Data qualifiers include the following:

U	Not detected at associated detection limit
J	Estimated concentration
UJ	Not detected; associated detection limit is an estimate
R	Rejected data, as determined during data validation
S	Sum of individual constituent concentrations (e.g., total cPAHs and total PCBs)
X	Elution pattern does not match typical product

4. Field duplicate samples are designated with sample ID suffixes of D, DUP, or SSE (the different suffixes have identical meanings).
5. As discussed in Section 2 of the report, soil quality data from the following areas have been redesignated as follows:
   - Areas AP-A and AP-G have been included in the Areas of Potential Concern tables.
   - Areas AP-B and AP-D have been included in Area 26.
   - Samples designated AP-H at the time of sampling have been divided into Areas 25 and 26.
   - Sampling locations within 25 feet of a narrow-gauge railroad grade have been included in the Narrow-Gauge Railroad designation.

The redesignated soil quality data have been included in soil quality data tables in this appendix for the appropriate areas as listed above.

The tables were developed on the basis of information provided to URS in an analytical database submitted in final form for this RI on April 1, 2002 (Pioneer 2002).
