EXECUTIVE SUMMARY

ES.1 Introduction

This Closure Report provides complete documentation of the remediation completed at Parcel One of the Former DuPont Works Site. Initially, the Former DuPont Works Site consisted of two Parcels, Parcel One and Parcel Two. Remediation of Parcel Two was completed in 1996, and is not addressed in this report. Parcel One is the subject of this report, and will be referred to as the Site for the remainder of the document.

The remediation documented in this report fulfills the requirements of the First Consent Decree (No. 91 2 01703 1) and the Second Consent Decree (No. 03 2 10484 7), effective July, 1991 and August, 2003, respectively, between the lead agency, Washington State Department of Ecology (Ecology), and the principle responsible parties, Weyerhaeuser Company (Weyerhaeuser) and E.I. duPont de Nemours and Company, Inc. (DuPont). Per the Second Consent Decree, the final remediation activities were conducted in accordance with the requirements identified in the Model Toxics Control Act (MTCA) Chapter 70.105D Revised Code of Washington (RCW) and the Cleanup Regulation Chapter 173-340 Washington Administrative Code (WAC) as implemented by Ecology. The cleanup-action decisions are described in the Cleanup Action Plan (CAP) (Ecology, 2003), and are based on the Remedial Investigation (RI) (URS Inc. and PIONEER, 2003), Risk Assessment (RA) (PIONEER, 2002) and Feasibility Study (FS) (WSNW and PIONEER, 2003) as well as other relevant documents in the administrative record.

The purpose of this report is to provide complete documentation of all remediation activities conducted at the Site, and to document compliance with the remediation provisions specified in the CAP. The Site was broken down into five land-use areas (i.e., Commercial [CM], Golf Course [GC], Industrial [IN], Historical [HI], and Open Space [OS] areas). The remedial actions conducted across the Site are described separately for each of the five land-use areas to enable a focused review of the separate areas of the Site to facilitate Site redevelopment. Archives of archeological work conducted at the Site, a complete listing of confirmation soil sampling results, background Site reports, specific remedial action program reports, and Site health and safety program reports are presented in Appendices.

ES.2 Summary of Site Remediation

Remedial actions at the Site included:

- Interim Remedial Action (IRA)
- Localized removal at Miscellaneous Small Remediation Units (MSUs) (e.g., removal of debris piles and stockpiles)
- Tree Root Zone Remediation
- Large-Scale Excavation (focused on arsenic and lead impacted surface soil)
- Capping

Numerous phases of remediation work have occurred at the Site. These remedial actions are briefly summarized below for the CM, GC, IN, HI, and OS areas, and the future land-use areas are presented in Figure ES-1.

ES.2.1 Commercial Area Remediation

The portion of the Site that was remediated for commercial land use comprised approximately 336 acres, which was divided into eight separate areas called Remediation Units (RUs). Remediation completed within the CM Area RUs included:

- IRAs (including excavation of soil and/or debris in hotspot areas and other areas where removal was required before other sequenced remediation could occur)
- MSU remediation
- Tree remediation
- Large-Scale Excavation

In addition, there was one RU that was designated for No Further Action based on the results of a comprehensive sampling program. The remedial actions completed within the eight CM Area RUs removed elevated levels of metals (i.e., arsenic, copper, and lead), explosives (i.e., 2,4-Dinitrotoluene [2,4-DNT], 2,6-Dinitrotoluene [2,6-DNT], nitrobenzene, and 2,4,6-Trinitrotoluene [TNT]), and petroleum hydrocarbons (Bunker-C fuel oil and motor oil). Figures showing all sampling locations, and the corresponding tables reflecting the soil sampling results associated with these locations, are presented in Appendix B. The sampling results presented in the Appendix B tables document the constituent concentrations that remain in place (i.e., those concentrations that met the Site cleanup levels (CLs), remediation levels (RLs), or screening level (SL) but did not meet Washington State standards for unrestricted land use). CLs were either MTCA table values derived by Ecology using default exposure assumptions, or Site-specific values derived by Ecology. RLs were derived using human health risk assessment procedures, incorporating exposure assumptions and other media-specific factors reflecting future Site conditions. There was one SL used, which was a value for lead derived by Ecology for protection of terrestrial ecological receptors. The sample results include both confirmation samples collected during Site remediation, and historical samples collected during the RI that had concentrations that met the applicable Site CLs, RLs, or SL. These concentrations document that Site remediation in the CM Area was completed in compliance with the CAP established by Ecology in 2003 (Ecology, 2003), and show that these areas are ready for future commercial development.

ES.2.2 Golf Course Area Remediation

The GC Area is 197 acres in size and consists of Placement Areas (PAs) and Non-Placement Areas (non-PA). GC Area PAs are discrete areas within the GC footprint where impacted soil from other areas of the Site were placed, and comprise approximately 75 acres. Non-Placement Areas within GC Area RUs are all areas within the GC footprint that are not PAs, and they comprise approximately 121 acres. These PAs were capped with at least one foot of gravel and six inches of soil.

The GC footprint was broken up into smaller RUs, which were designed to be similar in size. Within

each GC Area RU, there was both a PA and a non-PA.

Remediation completed within the PAs included IRA removal of soil when constituent concentrations were greater than the GC Area PA RLs. The soil with constituent concentrations greater than the GC Area PA RLs were placed on an asphalt pad and were either included in the arsenic and lead soil-screening program or sent off Site for disposal (PIONEER and WSNW, 2002). Contaminated soil from other areas on Site that had concentrations lower than the PA RLs, but above CLs, were then placed in the PAs, and the PAs were capped per the requirements of the CAP to prepare for construction of the GC.

Remediation completed within the non-PA GC Area RUs included:

- IRAs
- MSU remediation
- Tree remediation
- Large-Scale Excavation

The remedial actions completed within the eight GC Area RUs removed elevated levels of metals (i.e., arsenic, copper, and lead), explosives (i.e., 2,4-DNT, 2,6-DNT, nitrobenzene, and TNT), petroleum hydrocarbons (Bunker-C fuel oil and motor oil), and tetrachloroethene. Confirmation soil sampling results documenting the constituent concentrations that remained in place (i.e., those concentrations that met the CLs, RLs, or SL) are presented in Appendix B. These data document the successful completion of remedial activities in the GC Area RUs and that these activities were completed in a manner consistent with the CAP established by Ecology (Ecology, 2003). In addition, Appendix F presents data and As-builts that demonstrate that the ecocap and human health cap were constructed in a manner that met the design requirements identified in the CAP.

ES 2.3 Industrial Area Remediation

The northeast area of the Site will be used for industrial purposes as well as open space. The Industrial Area occupies 35.7 acres. Remediation completed within the Industrial Area included:

- IRAs
- MSU remediation

Remedial actions completed in the Industrial Area removed elevated levels of arsenic, lead, 2,4-DNT, 2,6-DNT, and TNT. Confirmation soil sampling results documenting the constituent concentrations that remained in place (i.e., those concentrations that met the CLs) are presented in Appendix B. The Industrial Area is in compliance with the CLs approved by Ecology in the 2003 CAP and this area is now ready for development for industrial uses.

ES 2.4 Historical Area Remediation

Four Historical (HI) Areas were identified at the Site, including the 1833 Fort Nisqually Site (Historical Site Number 45PI55), the Fort Nisqually Cemetery (Historical Site Number 45PI404), the Shell Midden (Historical Site Number 45PI72), and an area where Native American graves were found (Historical Site

Number 45PI712). In total, the HI Areas consisted of approximately six acres. Remedial actions completed in the HI Areas included:

- MSU remediation
- Capping

Each HI Area was assigned an RU number. Fort Nisqually was identified as RU HI-01, Fort Nisqually Cemetery was identified as RU HI-02, Native American Graves were identified as RU HI-03, and Shell Midden was identified as RU HI-04. Minimal remediation was done in the HI Area RUs to ensure the preservation of the historical artifacts. All work was completed under the direction/supervision of Historical Research Associates (HRA), the Nisqually Tribe, and the Washington State Department of Archaeology and Historic Preservation (DAHP). The remedial actions completed in the HI Areas included small-scale excavations of lead-contaminated soil in HI Area RU HI-01, and capping in the remaining three HI Areas. The constituents that were present above CLs, RLs, and SL were aldrin, arsenic, and lead. Soil sampling results documenting the constituent concentrations that remain in place are presented in Appendix B. Soil concentrations of arsenic and lead in HI-02, HI-03, and HI-04 were higher than the CLs in some instances. However, a protective cap constructed in the same manner as the GC cap (see Section 3.6) was placed over these areas to prevent exposure to human and ecological receptors. Therefore, the remedial objectives identified in the CAP established by Ecology (Ecology, 2003), were met in all HI Areas.

ES 2.5 Open Space Area Remediation

Four areas of the Site were designated for use as OS. Two OS Areas are located in the northeastern portion of the Site and are separated by Sequalitchew Creek, another is along the northern border of the Site and the last is the area surrounding Old Fort Lake. The OS Areas comprise approximately 72.2 acres. Remediation completed within the OS Areas included:

- IRAs
- MSU remediation
- Tree remediation
- Large-Scale Excavation

Minimal Large-Scale Excavation was conducted in the OS Areas due to the sensitive nature of the areas, and the overriding goal of trying to protect ecological habitat. The remedial actions were completed within the four OS Areas to remove elevated levels of arsenic and lead. Confirmation soil sampling results representing the constituent concentrations that remain in place (i.e., those concentrations that met the applicable CLs, RLs, and SLs) are presented in Appendix B. These data document the successful completion of remedial activities in the OS Areas and provide evidence that these activities were completed in a manner consistent with the CAP established by Ecology (Ecology, 2003).

ES.3 Conclusions

All land-use areas across the Site were successfully remediated in a manner consistent with the CAP established by Ecology (Ecology, 2003), and all areas of the Site are now ready for future development consistent with their land-use designation.

SECTION 1 – INTRODUCTION

1.1 Introduction

This Closure Report provides complete documentation of the remediation completed at Parcel One of the Former DuPont Works Site. Initially, the Former DuPont Works Site consisted of two Parcels, Parcel One and Parcel Two. Remediation of Parcel Two was completed in 1996, and is not addressed in this report. Parcel One is the subject of this report, and will be referred to as the Site for the remainder of the document.

The remediation documented in this report fulfills the requirements of the First Consent Decree (No. 91 2 01703 1) and the Second Consent Decree (No. 03 2 10484 7), effective July, 1991 and August, 2003, respectively, between the lead agency, Washington State Department of Ecology (Ecology), and the principle responsible parties, Weyerhaeuser Company (Weyerhaeuser) and E.I. duPont de Nemours and Company, Inc. (DuPont). Per the Second Consent Decree, the final remediation activities were conducted in accordance with the requirements identified in the Model Toxics Control Act (MTCA) Cleanup Regulation (MTCA) Chapter 70.105D Revised Code of Washington (RCW) and the Cleanup Regulation Chapter 173-340 Washington Administrative Code (WAC) implemented by Ecology. The cleanup action decisions are described in the Cleanup Action Plan (CAP) (Ecology, 2003), and are based on the Remedial Investigation (RI) (URS Inc. and PIONEER, 2003), Risk Assessment (RA) (PIONEER, 2002) and Feasibility Study (FS) (WSNW and PIONEER, 2003) as well as other relevant documents in the administrative record.

This section presents the purpose of this report, the Site setting, Site background (i.e., property history and regulatory history), summary of site contamination, an overview of soil and debris remedial actions, an overview of the Site's Cultural and Archaeological Monitoring Plan, and a description of the overall report organization. Investigations and remediation work that were conducted at the Site were documented in a variety of reports that are briefly summarized and referenced in this Closure Report. All activities described in this report were conducted under the supervision of both Weyerhaeuser and DuPont (the Companies). West Shore Corporation (now called Pacific Environmental and Redevelopment Corporation) performed the day-to-day project management, and Active Construction was the remediation contractor.

1.2 Purpose

The purpose of this report is to provide complete documentation of all remediation activities conducted at the Site, and to document compliance with the remediation provisions specified in the CAP (Ecology, 2003). In addition, this report documents the post-remediation environmental conditions.

1.3 Setting

The Site is located within the limits of the City of DuPont in Pierce County, Washington, as shown in Figure 1-1. The Site is surrounded by Northwest Landing property, which is owned by Weyerhaeuser (to

the north and west) and Quadrant Real Estate Company property (to the east, and south). Burlington Northern railroad property is adjacent to the Weyerhaeuser property to the west. Puget Sound is located to the west of the Burlington Northern Railroad property.

The significant physical features of relief across the Site are numerous glacial kettles (i.e., depressions), the east-west trending valley of Sequalitchew Creek, a steep bluff that partially borders Burlington Northern Railroad property, and a small kettle lake in the southern portion of the Site called Old Fort Lake. Site elevations generally range from 200 to 225 feet above mean sea level (MSL), except within the kettles where elevations are approximately 150 feet above mean sea level (MSL).

1.4 Site Background

1.4.1 Property History

Native Americans originally inhabited the Site property. European settlement began in 1832, when the Hudson's Bay Company established a cabin/storehouse adjacent to Puget Sound at the mouth of Sequalitchew Creek, northwest of the Site. In 1833, the Hudson's Bay Company built Fort Nisqually, which was located in the northern portion of the Site. Ten years later, a new Fort Nisqually was built at a location adjacent to, but outside the eastern edge of the Site.

DuPont acquired the Site and adjacent areas in 1906 and constructed an explosives-manufacturing plant and the Historical Village of DuPont as a company town for plant workers. The Historical Village of DuPont is approximately one mile southeast of the Site (see Figure 1-1). DuPont manufactured explosives until the mid-1970s, when it sold the Site and adjacent areas to Weyerhaeuser. Weyerhaeuser and its subsidiary, Quadrant, still own much of the approximately 2,500 acres in the area, which they named Northwest Landing. Northwest Landing is a planned community within the City of DuPont and includes the Site. Quadrant has begun to develop Northwest Landing, but will not be allowed to develop the Site until cleanup is complete and approved by Ecology.

1.4.2 Regulatory History

The Site and Parcel Two were used for manufacturing commercial explosives from 1909 to 1976. Production of explosive materials ceased, and decommissioning of the buildings began in 1976, when Weyerhaeuser purchased the property from DuPont. As part of the cleanup process, asbestos was removed, salvageable materials were recovered, and structures were either burned or demolished. Actions taken at the Site subsequent to the shutdown in 1976 include the following:

- In 1985, Weyerhaeuser initiated studies to determine whether or not hazardous substances were present.
- In 1986, a Phase I Site Survey and Review was conducted to identify areas on Site that may have been of environmental concern (Hart Crowser, 1986).
- In 1986, soil contamination was first documented and reported to Ecology.
- In 1987, a Phase II Site Characterization study was performed, which characterized the type, concentration, and distribution of constituents at 38 areas on Site (Hart Crowser, 1987).

- In 1989, a Baseline Human Health Risk Assessment was performed using results of the Phase II study.
- In 1991, the Companies signed a Consent Decree (No. 91 2 01703 1) with Ecology, where they agreed to study the site and complete an RI, RA, and FS. The property was then divided into two main areas: Parcel 1 (approximately 841 acres), and Parcel 2 (approximately 205 acres).
- In 1994 and 1995, draft RI, RA, and FS reports were submitted to Ecology and underwent public review (Hart Crowser, 1994a, 1994b, 1994c).
- In 1996, based on the results of interim source removal actions, Ecology approved a CAP for Parcel 2. The CAP allowed for no further remediation activities at Parcel 2, except for the institutional controls that maintained the industrial use of Parcel 2 (Ecology, 1996).
- In 1997, Parcel 2 was deleted from the Consent Decree, and the deed requiring institutional controls to maintain the industrial use was recorded in the Pierce County Assessor's Office.
- Between 1990 and 2002, while studies and negotiations were ongoing, the Companies undertook interim source removal actions to cleanup soil and/or debris at the Site, in accordance with MTCA (Ecology, 2001a) and the Consent Decree.
- In 2003, to fulfill the provisions of the Consent Decree, final RI, RA, and FS reports were prepared. A description of the contents of each of these reports is presented below.
    - RI – The purpose of the RI was to collect sufficient information regarding the Site to enable the completion of the RA and FS. The RI characterized the nature and extent of contamination based on the existing conditions at the Site. The RI report presented the analytical data for the media that were collected at the Site. The data were presented for each RI area, which were defined based on historical manufacturing and production operations at the Site (URS Inc. and PIONEER, 2003).
    - RA – The RA evaluated Site conditions in relation to future land uses. The RA identified default soil cleanup levels (CLs) used for screening and presented the methods used to derive Site-specific remediation levels (RLs) protective of human health and ecological receptors based on future land use. These CLs and RLs were compared to Site–specific constituent concentrations to identify areas requiring additional evaluation in the FS (PIONEER, 2002).
    - FS – The FS evaluated potential cleanup methods designed to meet the remedial action objectives for the Site. The FS report provided information for the Companies to recommend options for remediation of selected areas, including both no action and action methods. Ecology evaluated the FS and selected the remedial measures it believed were appropriate (WSNW and PIONEER, 2003).
- In 2003, the Companies completed the detailed design and implementation of the remedial measures selected by Ecology in the CAP (Ecology, 2003). This decision was captured in a new Consent Decree (No. 03 2 10484 7), which was agreed to by the Companies and Ecology and was

entered by the Court on August 15, 2003.

1.5 Summary of Site Contamination

Site contamination resulted from manufacturing and from decommissioning the former explosives manufacturing facility. While the contamination was Site-wide, the highest concentrations occurred in areas associated with former building foundations, in areas where manufacturing materials were disposed, and along the Narrow Gauge Railroad (NGRR) tracks. NGRR tracks are located throughout the Site, and depicting them on figures would obscure other features. Therefore, they have been depicted only in Open Space (OS) Area figures, where their location does not hide other features of interest. The potentially contaminated media on Site included surface water and sediment, groundwater, and soil and debris. An overview of the contamination associated with each medium is presented below.

1.5.1 Surface Water and Sediment

Three surface water bodies (i.e., Puget Sound, Sequalitchew Creek, and Old Fort Lake) are located within or adjacent to the Site. Puget Sound is a large saltwater body located along the western boundary of the Burlington Northern Railroad west of the Site. Puget Sound directly and/or indirectly receives all groundwater and surface water discharge from the Site.

Constituent concentrations detected in surface water in Sequalitchew Creek and Old Fort Lake are consistent with those detected at the area background (i.e., upstream) sampling locations in Sequalitchew Creek and in other rivers and streams in Pierce County. Water samples were also collected from two seep-sampling locations that discharge Site groundwater to the intertidal area of Puget Sound. This groundwater discharge is naturally saline due to saltwater intrusion, which disqualifies it as a drinking water source in accordance with MTCA. Total dinitrotoluene (total DNT), which is the sum of 2,4-dinitrotoluene (2,4-DNT) and 2,6-dinitrotoluene (2,6-DNT), concentrations have ranged from nondetect to 0.27 µg/L in the 25 samples collected from SEEP 1 over the period of monitoring. DNT has not been detected in SEEP 2. All detected DNT concentrations at SEEP 1 have been at least 33 times lower than the protective surface water concentration of 9.1 µg/L. Based on this comparison, DNT in groundwater discharging from the Site via seeps to Puget Sound poses no concern to human health or the environment. A wide range of constituents was analyzed for the sediment samples, however none were detected at elevated concentrations.

Based on the data presented in the 1994 Draft RI report, Ecology verbally agreed to No Further Action for surface water and sediment within Site (Ecology 1996).

1.5.2 Groundwater

The only constituents detected at elevated concentrations in groundwater since 1996 were the isomers 2,4-DNT and 2,6-DNT. Because detected DNT concentrations were consistently low, were not affecting the regional aquifer, were not affecting surface water, and the aquifer was not used as a drinking water source, Ecology determined that no active remedial action was necessary, and long-term monitoring at selected wells would be sufficient (Ecology, 1996).

1.5.3 Soil and Debris

Of the 213 constituents evaluated during Site characterization, the RA identified only 11 constituents in soil (i.e., aldrin, arsenic, benzo(a)pyrene, DNT, copper, lead, mercury, nitrobenzene, 2,4,6-trinitrotoluene [TNT], tetrachlorethene, and total petroleum hydrocarbon [TPH]) as exceeding levels of concern for human and/or ecological receptors. Site soil contamination occurred as two distinct categories:

1. Widespread arsenic and lead impacted surface soil
2. Isolated, small occurrences of TPH, mercury, DNT and TNT, nitrobenzene, benzo(a)pyrene, aldrin, tetrachloroethylene, copper, and/or arsenic/lead impacted subsurface (i.e., depth greater than one foot below ground surface [bgs]) soil

Debris was primarily contaminated with lead in the form of lead-based paint. The total volume of contaminated soil was approximately 905,000 cubic yards (CY), and arsenic and lead contaminated soil accounted for approximately 96 percent of this volume.

1.6 Overview of Soil and Debris Remedial Actions

Remedial actions at the Site included interim remedial actions (IRAs), localized removal at miscellaneous small units (MSUs) (e.g., removal of debris piles and stockpiles), tree remediation, large-scale excavation focused on arsenic and lead impacted surface soil, and capping. These remedial actions occurred in several areas of the Site, and are discussed separately for each future land use area (i.e., Commercial [CM], Golf Course [GC], Industrial [IN], Historical [HI], and OS Areas). In general, these remedial actions consisted of the following:

- **Interim Remedial Actions:** IRAs were localized soil and/or debris removal actions conducted to minimize the potential for transport of residual constituents in soil, to protect groundwater (thereby minimizing potential future environmental impacts), to improve the safety and environmental conditions at the Site, to remove debris and facilitate a more complete and accurate RI, and to prepare for the final remediation of the Site. Materials were recycled off Site, incinerated off Site, or sent to an approved landfill. IRAs were completed around former Bunker-C pipelines and above-ground storage tanks, around building foundations, the former narrow gauge railroad, the soil and sand laydown areas, along a 250-foot swath of land on the southern perimeter of the Site, and in areas where there were elevated mercury concentrations. For each IRA, complete work plans were developed, reviewed by Ecology, and revised in accordance with their comments. Each IRA was described in a series of Interim Source Removal Memoranda submitted to Ecology following completion of the work.
- **Localized Removal at Miscellaneous Small Units:** MSUs were identified as areas where isolated, small occurrences of TPH, mercury, DNT and TNT, nitrobenzene, benzo(a)pyrene, aldrin, tetrachloroethylene, copper and/or arsenic/lead were found in subsurface soil (i.e., soil at a depth greater than one foot bgs). MSUs represented less than one percent of the total volume of contaminated soil on Site. Some of the soil from the MSUs was excavated and disposed of on Site in placement areas (PAs) within the GC, and some was transported off Site for disposal at an

Ecology/United States Environmental Protection Agency (EPA) approved landfill. Contaminated debris occurred on Site as piping, brick and other construction materials painted with lead-based paint. Stockpiles of formerly excavated material primarily consisted of soil, although in some cases there was also demolition debris. Debris and stockpile materials were sampled to characterize the constituent (e.g., arsenic, lead, etc.) concentration. Depending on the concentration, they were either excavated and disposed of on Site in PAs within the GC Area, or transported off Site for disposal at an Ecology/EPA approved landfill.

- **Tree Root Zone Remediation:** The purpose of this remedial action was to preserve selected trees within the future GC footprint. This remedial action involved sampling soil within tree drip lines (i.e., the approximate horizontal distance of the outstretched limbs and roots) for arsenic and lead. In instances where the arsenic CL or lead SL were exceeded, one foot of soil was carefully removed within the drip line of the tree, soil samples were collected, and the excavation was immediately filled with clean topsoil. If confirmation sample results exceeded the applicable cleanup goals, additional rounds of excavation and confirmation sampling were conducted until the remediation goals were achieved.
- **Large-Scale Excavation:** Large-Scale Excavation involved excavation of one foot of soil over large areas of the Site where elevated levels of arsenic and lead were present. Following excavation, confirmation samples were collected to confirm that the applicable cleanup goals were met. Where goals were not achieved, additional excavation was conducted until goals were met. Excavated soil was disposed of on Site in PAs within the GC Area.
- **On-Site Deposition with a Cap/Cover (Golf Course):** The majority of contaminated soil excavated from the Site was deposited in PAs that were located within the GC footprint. The contaminated soil was then covered with a cap that consisted of at least 12 inches of compacted gravel that was then topped with a minimum of six inches of clean soil.
- **Cap/Cover of Historical Areas:** Contaminated soil in the HI Areas was covered with a cap that consisted of at least 12 inches of compacted gravel that was then topped with a minimum of six inches of clean soil. After the minimal cap thickness was met, where planting was specified, additional soil was added to the depth necessary to cover the root ball of the designated plant(s).

1.7 Cultural and Archaeological Management Plan

All remediation work was done in accordance with the project's Cultural Resources Protection Plan (Historical Research Associates, Inc. [HRA], 2002). This plan, which was based upon cooperative agreements established between Weyerhaeuser, the Nisqually Tribe, and the Washington State Department of Archaeology and Historic Preservation (DAHP), identified the following guidelines for Site remediation and construction activities:

- Prior to the start of fieldwork, the Project's Archaeology Consultant (i.e., HRA) trained (or re-trained) all individuals involved in the program to identify items of cultural or historic significance.
- HRA was hired to monitor all clearing and excavation phases of the program.

- When a potential item of cultural or historic significance was discovered during Site preparation or field activities, all work in that area was stopped until all stakeholders were consulted.

In addition to the conditions of this agreement, the following was done:

- A representative of the Nisqually Tribe was hired by the Project Manager to monitor all excavation activities.
- Ecology, the Nisqually Tribe, and DAHP were formally contacted when a potential item of cultural or historic significance was discovered during Site preparation or field activities, with the exception of DuPont Works-era materials.

Multiple reports describing the processes used by HRA to monitor activities, and a description of any findings, were prepared and forwarded to Ecology, the Nisqually Tribe and DAHP. All of the reports prepared by HRA are included in this report in Appendix A.

1.8 Report Organization

A description of the Site remediation activities and the confirmation soil sampling conducted in each area of the Site is provided in the following sections. General descriptions of the remedial actions and technical construction specifications for remedial measures are provided in the Remedial Design Report for the Former DuPont Works Site (PIONEER, WSNW, and Asmundson, 2003).

Remediation was performed in accordance with the CAP (Ecology, 2003) to support the designated future uses of the Site. Future land uses, according to the Final Environmental Impact Statement (EIS) include CM, GC, IN, HI, and OS Areas. The Site future land-use areas are shown in Figure 1-2. Remediation of each area of the Site was conducted until soil concentrations in each area achieved the applicable cleanup goals, which were CLs, RLs, or a screening level (SL) specified for the future land use of that area. CLs were either MTCA table values derived by Ecology using default exposure assumptions, or Site-specific values derived by Ecology. RLs were derived using human health risk assessment procedures, incorporating exposure assumptions and other media-specific factors reflecting future Site conditions. There was one SL used, which was a value for lead derived by Ecology for protection of terrestrial ecological receptors. The sources of the CLs, RLs, and the SL used in this report are documented in the RA (PIONEER, 2002).

The Site remediation activities are presented in the following sections, organized by the designated future land-use areas:

- Commercial (Section 2)
- Golf Course (Section 3)
- Industrial (Section 4)
- Historical (Section 5)
- Open Space (Section 6)

The areas where specific remediation activities (e.g., IRAs, MSUs, Tree Remediation, etc.) occurred were

identified for each future land use. In some instances, areas with specific remediation activities may overlap future land-use areas (e.g., one MSU may stretch across the boundaries of both a CM and a GC area). When an overlap occurred, the remediation activity was addressed in both future land-use sections. Therefore, each section of the report contains a complete remediation picture for each future land-use area.

The final section of the report presents the Health and Safety Program for Site remediation, and summarizes air monitoring that was conducted as part of the program.

SECTION 2 – COMMERCIAL AREA REMEDIATION

2.1 Introduction

The CM Area constitutes the majority of the Site property. Most of the soil in this area will be covered by buildings, parking lots, and roads to allow for future commercial use such as offices and retail businesses. The portions of the CM Area that will not be covered by buildings or parking lots will have sidewalks and professionally landscaped and maintained areas.

The portion of the Site that was remediated for CM land use comprised approximately 336 acres (see Figure 2-1), which was divided into eight separate areas called Remediation Units (RUs). In the RA, however, nine CM Area RUs were identified. For this report, the former RU CM-08 was integrated into RUs CM-01 and CM-02. The former CM-09 then became CM-08. In addition, there was one RU (i.e., the newly designated CM-08) that was designated for No Further Action (NFA) based on the results of a comprehensive sampling program (see Section 2.6). Remediation completed within the CM Area RUs included:

- IRAs
- MSU remediation
- Tree root zone remediation
- Large-Scale Excavation

The CLs, RLs, and SL identified for the CM Area are shown in Table 2-1. Following completion of all of the remedial actions, the soil in all of the CM Area RUs met the applicable CLs, RLs, and the SL. Results of all confirmation soil sampling completed in the CM Area RUs, which identify the soil constituent concentrations left in place following remediation, are presented in Appendix B. The remedial actions are discussed below.

2.2 Interim Remedial Actions

IRAs were conducted in the CM Area RUs between 1992 and 2002, and included removal of a buried Bunker-C pipe and above-ground fuel storage tanks, and the excavation of the associated contaminated soil; excavation of soil around building foundations; excavation of soil along the NGRR; excavation of soil hotspot concentrations; excavation of soil in future sand laydown areas; excavation of soil in future soil laydown areas; and excavation of soil in areas identified for additional characterization sampling and in perimeter areas. Removal of on-Site stockpiles was also completed as an IRA. The locations of IRA areas within the CM Area RUs are shown in Figure 2-2. Each of these actions is described briefly below:

2.2.1 Removal of Bunker-C Pipe, Storage Tanks, and Soil Excavation

The purpose of this IRA was to remove buried Bunker-C pipeline sections, above-ground storage tanks, and the associated contaminated soil. Pipe sections and the above-ground storage tanks were removed,

steam cleaned, and taken off Site for disposal. One section of the pipe, located in a sloped area, was drained, cleaned, filled with grout and abandoned in place. Lead packing in the pipe joints was also removed and disposed of off Site. Following removal of the pipe and tanks, approximately 29,100 cubic yards of Bunker-C contaminated soil was removed, and 24 verification soil samples were taken from the former tank area and from the former pipeline stretch. Results of the verification sampling indicated that the former pipeline and tank area soil concentrations met the designated 570 mg/kg soil concentration for TPH.

The excavated soil was characterized for TPH concentrations, and was either disposed of off Site, or stockpiled for future use as backfill. Complete documentation of this IRA is contained in *Interim Source Removal Memorandum: Area 8 Pipeline and Former Above-Ground Storage Tanks, Former DuPont Works Site, DuPont Washington, Hart Crowser Document J-1747-64*, presented in Appendix C.

2.2.2 Foundation Excavations

The purpose of the foundation excavation program was to remove elevated arsenic and lead concentrations found in soil adjacent to building foundations. The source of arsenic was associated with use of herbicides, and the source of lead was lead sheeting that had been used to line the buildings, and lead-based paint chips that remained after building demolition. The locations of the foundations included in this IRA are shown in Figure 2-2. In this IRA, the top two feet of soil were excavated within 25 feet of selected foundations (i.e., buildings that had lead sheeting or lead paint). Following excavation at each location, a five-point composite confirmation sample was collected, which consisted of soil taken from each of the four sides of the excavation, and from the floor of the excavation. Some locations required up to three rounds of excavation before the arsenic RL and the lead SL were met. At the conclusion of the IRA, there were three locations within CM-01 (F-79, F-80, and F-90, shown on a map in the associated report in Appendix C) where the lead SL of 118 mg/kg was not met. All three of these locations were included in CM Area MSUs, and remediated during a later stage of Site cleanup. Locations F-79 and F-80 were included in MSU-39, and location F-90 was included in MSU-52/53. Remediation of these MSUs is described in detail in Appendix D.

The soil excavated during this IRA was placed in one of the GC Area PAs. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hot Spots, April 22, 2002* memorandum presented in Appendix C.

2.2.3 Narrow Gauge Railroad Soil Excavation

The purpose of this IRA was to remove elevated arsenic concentrations associated with the NGRR, where an arsenic-containing herbicide had historically been used for weed control. In this IRA, 1.5 feet of soil was excavated within 25 feet of the centerline of the NGRR. Some of the NGRR was not excavated due to the close proximity of timber that was identified for future harvesting. All remaining portions of the NGRR were designated as MSUs (i.e., NGRR MSUs) and excavation was done as part of the final remediation (see Appendix D). Following excavation, one five-point composite confirmation sample was collected from the excavation floor every 50 feet along the NGRR. Some locations required three rounds of excavation to achieve the Site-specific arsenic RL of 60 mg/kg. One location (R47C71) with an

arsenic concentration of 89 mg/kg, which was greater than the RL, was left in place. This concentration was left in place in CM-08, which was designated as a NFA area. CM-08 was designated as a NFA area because when all of the sample results were grouped together, the arsenic and lead concentrations in this RU met the MTCA three-fold criteria. Designation of CM-08 as a NFA area is described in detail in Section 2.2.7

The soil excavated during this IRA was placed in one of the GC Area PAs. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hot Spots, April 22, 2002* memorandum presented in Appendix C.

2.2.4 Hotspot Area Excavations

Two separate IRAs were completed for the hotspot areas within the CM Area RUs. One IRA was completed in 2000 and the other was completed in 2001. These IRAs are described in the following paragraphs.

- 2000 Hotspot IRA: The purpose of these excavations was to remove soil hotspot concentrations of arsenic or lead that exceeded the GC Area PA RLs of 530 mg/kg for arsenic and/or 4,100 mg/kg for lead. Concentrations above these RLs required treatment and off- Site disposal. Following excavation, five samples were collected within each 50-foot by 50-foot excavation. This included four discrete samples taken on each wall of the excavation, and one composite sample collected from the excavation floor. Excavation proceeded in the hotspot areas until arsenic and lead concentrations met levels that could be retained on Site within GC Area PAs. The excavation depth of each hotspot location varied, and ranged from a total excavation depth of one foot to eight and a half feet.

  Hotspot soil were excavated and stockpiled for future treatment at the on-Site screening plant and subsequent disposal in an Ecology-approved off-Site landfill. After the hotspot concentrations were removed, these areas were incorporated into the Large-Scale Excavation areas in order to ensure compliance with the applicable CM RLs and SLs. Complete documentation of this IRA is contained in the *Hot Spot Interim Action Report, Former DuPont Works Site, DuPont, Washington, October 4, 2000* memorandum presented in Appendix C. Documentation of the treatment process for the soil excavated during this IRA is contained in the *Interim Source Removal Actions: Screening Plant Report, January 22, 2002* memorandum presented in Appendix C.

- 2001 Hotspot IRA: The purpose of this IRA was to remove soil concentrations of arsenic, 2,4-DNT, 2,6-DNT, and/or TNT that were elevated above the CM Area RL and CLs. The area and depth of excavation varied, depending on the size and location of the elevated concentration.
  - This IRA included excavation at one location where there was an elevated arsenic concentration. This location is identified and described in Section 2.2.7, Areas for Additional Characterization Sampling. At this location (R71C85), the arsenic concentration was 580 mg/kg. Soil was excavated to a depth of one and a half feet, and extended 25 feet out to the north, south, east, and west from the location of the elevated

concentration. Following excavation, five verification samples were collected, one from each wall of the excavation and one from the floor of the excavation. Confirmation samples indicated that all arsenic concentrations were below the CM Area RL.

- The 2,4-DNT, 2,6-DNT, and TNT hotspot area included in this IRA was located in former Area 18, which was incorporated into CM-02. Soil was excavated to a depth of three feet, and extended 15 feet out to the north, south, east, and west of the location of elevated concentration. Following excavation, one verification sample was collected from the floor of the excavation. This confirmation sample indicated that the remaining concentrations of 2,4-DNT, 2,6-DNT, and TNT were below the CLs.
- All excavated soil with arsenic contamination was placed in GC Area PAs, and all 2,4-DNT, 2,6-DNT, and TNT contaminated soil was stockpiled for off-Site disposal in an Ecology-approved landfill. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hot Spots, April 22, 2002* memorandum presented in Appendix C.

2.2.5 Sand Laydown Area Excavation

The purpose of this IRA was to excavate arsenic and lead contaminated soil to provide clean areas for sand storage (i.e., sand laydown areas). The sand was needed to construct the final capping layer of the GC Area. In this IRA, soil was excavated to a depth of one and a half feet within each of the five staked storage areas in the CM Area. Following excavation, one discrete confirmation soil sample was collected within each grid node of a 50-foot sampling grid. Sample results for each storage area were combined for comparison to the MTCA three-fold criteria for establishing compliance with the arsenic RL and the lead SL. To meet the MTCA three-fold criteria, the 95 percent Upper-Confidence Limit (95% UCL) of the Mean Concentration of all samples had to be lower than the applicable RL or SL, no more than 10 percent of the samples could have a concentration greater than the RL or SL, and no samples could have a concentration greater than two times the RL or SL. All sand laydown areas met these criteria.

The soil excavated during this IRA was placed in a GC Area PA. Complete documentation of this IRA is contained in the *Sand Laydown Area Interim Action Report, Former DuPont Works Site, DuPont Washington, November 16, 2000* memorandum presented in Appendix C.

2.2.6 Soil Laydown Area Excavations

The purpose of these excavations was to excavate arsenic and lead contaminated soil to provide clean areas for topsoil storage. In this IRA, soil was excavated to a depth of one and a half feet within the staked storage areas. Following excavation, one discrete confirmation soil sample was collected within each grid node of a 150-foot sampling grid. Following excavation, all sample locations met the CM Area RL for arsenic and SL for lead.

The soil excavated during this IRA was placed in a GC Area PA. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hotspots, April 22, 2002* memorandum presented in Appendix C.

2.2.7 Areas for Additional Characterization Sampling

The purpose of this sampling program was to characterize arsenic and lead concentrations in soil in areas located in northeastern and southeastern portions of the Site. This sampling was done to identify areas of the Site that could be left in their existing condition because remediation was not necessary. In this IRA, a 75-foot grid was established in each area, and one five-point composite sample was collected from each 75-foot sampling grid. Sampling results were combined for each area separately to determine if the areas could potentially be designated as NFA areas, based on compliance with the MTCA three-fold criteria for establishing compliance with the applicable RL or SL. To meet the MTCA three-fold criteria, the 95% UCL concentration of all samples needed to be lower than the RL or SL, no more than 10 percent of the samples could have a concentration greater than the RL or SL, and no samples could have a concentration greater than two times the RL or SL.

Sampling results for the northeastern portion of the Site (designated as CM 11 in the associated report in Appendix C) indicated that there were several locations with lead concentrations greater than twice the CM Area SL. Therefore, this area was no longer considered a candidate for NFA, and was integrated into other CM Area RUs identified for large-scale excavation.

Sampling results for the southeastern portion of the Site (designated as CMs 12 & 13 in the associated report in Appendix C) indicated that there were several locations in the southern portion of this area where arsenic and/or lead concentrations were greater than twice the RL or SL, causing the entire area to be out of compliance with the MTCA three-fold criteria. However, there was a large portion of the middle and northern parts of the sampling area where the MTCA three-fold criteria was met. To facilitate remediation, the areas with elevated arsenic and/or lead concentrations were carved out and integrated into other CM Area RUs identified for large-scale excavation. After these areas were carved out, there were two isolated sample locations, R66C88 and R71C85 that had arsenic concentrations greater than twice the RL. Location R66C88 became MSU-29 and the elevated arsenic concentration was removed during a later stage of Site remediation; location R71C85 was identified as a hotspot, and was removed during the Hotspot IRA completed in 2001, discussed in Section 2.2.4. The remaining portions of CMs 12 and 13 where the three-fold criteria were met were combined to form CM-08, which was identified as a NFA area.

Detailed results of this sampling program, including maps showing the location of the referenced sample locations, are contained in the *2001 Site Characterization Program: Areas for Additional Sampling Parcel 1 – Consent Decree, June 5, 2001* memorandum presented in Appendix C.

2.2.8 Perimeter Soil Excavation

The purpose of this excavation program was to remove soil having arsenic and lead concentrations greater than the arsenic RL of 60 mg/kg and the lead SL of 118 mg/kg within 250 feet of the southern Site boundary. In the 250-foot perimeter area, at least one foot of soil was excavated. One soil sample was collected from each node on the 75-foot sampling grid from a depth of zero to six inches, and was analyzed for arsenic and lead. After the initial excavation, all sample locations met the applicable RL and SL except for one, where the lead concentration (144 mg/kg) exceeded the SL. In this location, one

additional foot of soil was removed. When the location was re-sampled, the lead concentration was below the goal.

The soil excavated during this IRA was placed in a GC Area PA. Complete documentation of this IRA is contained in the *Perimeter Soil and Storm Water Runoff Overflow Pipeline Interim Corrective Action, November 2002* memorandum presented in Appendix C.

2.2.9 On-Site Stockpile Excavations

The purpose of this IRA was to characterize and designate the appropriate disposal option for 164 stockpiles of soil and/or debris located across the Site. These stockpiles were created as a result of IRAs conducted between 1991 and 1995. Based on the characterization of the stockpile materials, 14 stockpiles were identified for direct off-Site disposal, seven stockpiles were identified for screening followed by off-Site disposal, 139 stockpiles were identified for placement in the GC Area PAs, and four stockpiles were identified for use as general fill.

Complete documentation of this IRA is contained in the *Interim Source Removal Actions: On-Site Stockpiles Report at the Former DuPont Works Site, January 28, 2002* memorandum presented in Appendix C. Documentation of the treatment process for the seven stockpiles identified for screening and off-Site disposal is contained in the *Interim Source Removal Actions: Screening Plant Report, January 22, 2002* memorandum presented in Appendix C.

2.3 Miscellaneous Small Units (MSUs)

MSUs located within the boundaries of the CU Area RUs included debris piles, foundations, sections of the NGRR, and other localized areas with soil concentrations of arsenic, copper, lead, Bunker-C fuel oil, motor oil, nitrobenzene, and/or TNT that were elevated over applicable CM Area CLs, RLs, or SL. The MSUs, their associated constituents, and the CM Area RU in which they are located are presented in Table 2-2. Following remediation, the remaining constituent concentrations met the applicable CLs, RLs or the SL. The remedial action completed for each MSU is discussed in Appendix D.

2.4 Tree Root Zone Remediation

There were nine trees within the CM Area RUs that had soil removed around the base to remediate elevated levels of arsenic and lead. Trees were selected for remediation based on the goal of preserving a buffer around the perimeter of the Site. The locations of Tree Remediation Areas within the CM Area RUs are shown in Figure 2-3.

This remedial action involved sampling within tree drip lines (i.e., the approximate horizontal distance of the outstretched limbs and roots) for arsenic and lead. Where the arsenic RL or the lead SL were exceeded, one foot of soil was carefully removed within the drip line of the tree, soil samples were collected, and the excavation was immediately filled with clean topsoil. If confirmation sample results exceeded the RL or SL, additional rounds of excavation and confirmation sampling were conducted until the remediation goals were achieved. The tree root zone sampling and remediation program results are presented in Appendix E.

2.5 Large-Scale Excavation

Large-scale excavation of arsenic and lead contaminated soil was the primary type of remediation conducted in the CM Area RUs. Conducted in the areas shown in light blue in Figure 2-4, large-scale excavation consisted of the following steps:

- All trees were cleared from the area (with the exception of nine trees chosen for preservation)
- All remaining vegetation was removed
- A global positioning system (GPS) was used to determine the elevations prior to excavation on a 75-foot grid (or 65-foot grid, depending on the dimensions of the RU). The tolerance of the GPS is 8/100 of a foot on the horizontal axis and 5/100 of a foot on the vertical axis. Elevations were also determined at all grid-sampling locations.
- Excavators and off-road trucks were used to remove one foot of soil that was then placed in the GC Area PAs
- The GPS was used to confirm that at least one foot of soil was removed from grid locations

Following the excavation of soil, the resulting surface soil was sampled, with one five-point composite sample collected for each grid node. If sampling results indicated that constituent concentrations were below the RLs or SL, the remediation was considered complete for the area represented by the grid node. If constituent concentrations were found to be above the remediation goals, excavation activities were repeated within the grid box in one-foot increments until the remediation goals were met for the grid location.

Over 1,900 sample locations were established to determine whether or not the large-scale remediation in the CM Area RUs was adequate. Of these sample locations, 50 required a second round of excavation, two required a third round of excavation, and one required a fourth round of excavation to meet the associated remediation goals.

2.6 Summary of Remedial Actions in the Commercial Area

The remedial actions described in this section were completed within the eight CM Area RUs (i.e., CM-01 through CM-08) to remove elevated levels of metals (i.e., arsenic, copper, and lead), explosives (i.e., 2,4-DNT, 2,6-DNT, nitrobenzene, and TNT), and petroleum hydrocarbons (i.e., Bunker-C Fuel Oil and motor oil). Figures showing all sampling locations, and corresponding tables presenting the soil sampling results associated with these locations, are presented in Appendix B. The sampling results presented in the Appendix B tables document the constituent concentrations that remain in place (i.e., those concentrations that met the applicable Site CLs, RLs, or the SL). The sample results include both confirmation samples collected during Site remediation, and historical samples collected during the RI that had concentrations that met the Site remediation goals. These concentrations document that Site remediation in the CM Area RUs was completed in compliance with the CAP established by Ecology (Ecology, 2003), and show that these areas are ready for future commercial development.

Table 2-1 – Soil Cleanup Levels, Remediation Levels, and Screening Level Used for Evaluating Commercial Land Use

Constituent	Cleanup Goals (mg/kg)	Source
Explosives		
Dinitrotoluene - Total	3.0	Cleanup Level; based on Ecology Agreement (Ecology letter from Mike Blum to Jim Odendahl and Ron Buchanan, January 11, 2001). Total of 2,4-Dinitrotoluene and 2,6-dinitrotoluene concentrations.
Nitrobenzene	0.051	Cleanup Level; the MTCA Method B Value protective of Groundwater. The derivation of this value is presented in WAC 173-340-740.
2,4,6-Trinitrotoluene	1.75	Cleanup Level; based on Ecology Agreement (Ecology letter from Mike Blum to Jim Odendahl and Ron Buchanan, January 11, 2001).
Petroleum Hydrocarbons		
Bunker C – Motor Oil	7,600	Cleanup Level; based on Ecology Agreement (PIONEER Technologies Corporation. 2002. Human Health and Ecological Risk Assessment for the Former DuPont Works Site, DuPont, Washington, Appendix C)
Motor Oil	2,000	Cleanup Level; the MTCA Method A Table Value (173-340-745 WAC)
Inorganics		
Arsenic	60	Remediation Level; based on Ecology Agreement (Ecology letter from Mike Blum to Vern Moore and Izzy Zanikos, June 25, 1999).
Copper	263	Cleanup Level; the MTCA Method B Value protective of Groundwater. The derivation of this value is presented in WAC 173-340-740.
Lead	118	Screening Level; Ecology-derived soil screening value for protection of terrestrial ecological receptors (WAC 173-340-7493).

Table 2-2 – Miscellaneous Small Units In Commercial Areas

MSU	Constituents of Concern	RU Location of MSU[1]
MSU-01	Motor Oil (Bunker C)	CM-01
MSU-02	Motor Oil (Bunker C)	CM-01
MSU-03	Lead	CM-01
MSU-13	Lead	CM-01
MSU-22	Nitrobenzene	CM-02
MSU-23	Nitrobenzene	CM-02
MSU-24	2,4,6-Trinitrotoluene	CM-02

SECTION 3 – GOLF COURSE AREAS

3.1 Introduction

The GC Area is 197 acres in size and consists of Placement Areas (PAs) and Non-Placement Areas (non-PAs). GC Area PAs were discrete areas within the GC Area that were used to place contaminated soil from other areas of the Site, and comprise approximately 75 acres of the 197-acre GC Area. After placement, the contaminated soil was covered with a cap that consisted of at least 12 inches of compacted gravel that was then topped with a minimum of six inches of clean soil. Non-Placement Areas comprised approximately 121 acres of the GC Area.

The GC Area was broken up into smaller RUs, GC–01 through GC–08, which were designed to be similar in size. Within each GC Area RU, there were both PAs and non-PAs.

Remedial actions completed in the GC Area RU PAs included IRA removal of soil with concentrations of explosives (i.e., 2,4-DNT, 2,6-DNT, and TNT), arsenic, and lead, that were greater than their associated CLs, RLs, or SL (see Table 3-1). The arsenic and lead soil with constituent concentrations greater than the GC Area PA RLs were placed on an asphalt pad and were either included in the arsenic and lead soil-screening program or sent off Site for disposal (PIONEER and WSNW, 2002). Arsenic and lead contaminated soil from other areas on Site were then placed in the PAs, and the PAs were capped.

Remediation completed within the non-PA GC Area RUs included:

- IRAs
- MSU remediation
- Tree Root Zone remediation
- Large-Scale Excavation

These remedial actions are discussed in more detail later in this section.

The eight GC Area RUs are shown in Figure 3-1. The remediation goals for the GC Area RUs (including both GC Non-PA and PA areas), are shown in Table 3-1. Following completion of all soil removal remedial actions, the soil in all of the GC Area RUs met the applicable CLs, RLs and the SL. Results of all confirmation soil sampling completed in the GC Area RUs, which identified the soil constituent concentrations left in place following remediation, are presented in Appendix B.

The following sections describe the soil removal actions (i.e., the IRAs, MSU remediation, tree remediation, and large-scale excavation), the PA cap construction, and the GC construction.

3.2 Interim Remedial Actions

IRAs were conducted in the GC Area RUs between 1998 and 2001, and included removal of Bunker-C pipe, storage tanks, and the associated affected soil; excavation of soil around building foundations; excavation of soil along the NGRR; excavation of soil in hotspot areas; excavation of soil in the sand

laydown areas; and excavation of soil along the trench where a storm-water runoff pipe was to be installed. Removal of on-Site stockpiles was also completed as an IRA. The locations of IRA areas within the GC Area RUs are shown in Figure 3-2. The GC Area IRAs are briefly described below.

3.2.1 Removal of Bunker-C Pipe, Storage Tanks, and Soil Excavation

The purpose of this IRA was to remove buried Bunker-C pipeline sections, above-ground storage tanks, and the associated contaminated soil. Pipe sections and the above-ground storage tanks were removed, steam cleaned, and taken off Site for disposal. One section of the pipe, located in a sloped area, was drained, cleaned, filled with grout and abandoned in place. Lead packing in the pipe joints was also removed and disposed of off Site. Following removal of the pipe and tanks, approximately 29,100 cubic yards of Bunker-C contaminated soil was removed, and 24 verification soil samples were taken from the former pipeline stretch and from the former tank area. Results of the verification sampling indicated that the former pipeline and tank area soil concentrations met the CL soil concentration of 570 mg/kg for TPH.

The excavated soil was characterized for TPH concentration, and was either disposed of off Site or stockpiled for future use as backfill. Complete documentation of this IRA is contained in *Interim Source Removal Memorandum: Area 8 Pipeline and Former Above-Ground Storage Tanks, Former DuPont Works Site, DuPont Washington, Hart Crowser Document J-1747-64*, presented in Appendix C.

3.2.2 Foundation Excavations

The purpose of this excavation program was to remove elevated lead concentrations found in soil adjacent to building foundations (the arsenic RL of 60 mg/kg was met at all locations). The source of this lead was lead sheeting that had been used to line the buildings, and lead-based paint chips that remained after building demolition. In this IRA, the top two feet of soil was excavated within 25 feet of selected foundations (i.e., buildings that had lead sheeting). Some locations required up to three rounds of excavation before remediation goals were met. There were four locations within GC-01 (F-244, F-249, F-252, and F-254, shown on a map in the associated report in Appendix C) where the lead SL of 118 mg/kg was not met. All four of these locations were included in GC Area MSUs, and were remediated during final Site cleanup. Location F-244 was included in MSU-59, location F-249 was included in MSU-58, location F-252 was included in MSU-57, and location F-254 was included in MSU-55. Remediation of these MSUs was completed in a later stage of Site remediation, and is described in detail in Appendix D.

The soil excavated during this IRA was placed in one of the GC Area PAs. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hotspots, April 22, 2002* memorandum presented in Appendix C.

3.2.3 NGRR Excavations

The purpose of these excavations was to remove elevated arsenic concentrations that were associated with the NGRR, where an arsenic-containing herbicide had historically been used for weed control. In this IRA, one and a half feet of soil was excavated within 25 feet of the centerline of the NGRR. A portion of the NGRR was not excavated due to the close proximity of timber that was identified for future

harvesting or because it was inside the GC Area. The remaining portion of the NGRR, outside of the GC Area PAs, was designated as an MSU (i.e., NGRR MSU) and excavation was done as part of the final remediation (see Appendix D). Following excavation, one five-point composite confirmation sample was collected from the excavation floor every 50 feet along the NGRR. Some locations required three rounds of excavation to achieve the arsenic RL of 60 mg/kg.

The soil excavated during this IRA was placed in one of the GC Area PAs. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hotspots, April 22, 2002* memorandum presented in Appendix C.

3.2.4 Hotspot Areas Excavations

Two separate IRAs were completed for the hotspot areas within the GC Area RUs. One IRA was completed in 2000, the other IRA was completed in 2001. These IRAs are described in the following paragraphs.

- 2000 Hotspot IRA: The purpose of this excavation was to remove hotspot area concentrations of arsenic and lead that exceeded the GC Area PA RLs of 530 mg/kg for arsenic and 4,100 mg/kg for lead. Following excavation, five samples were collected within each 50-foot by 50-foot excavation. This included four samples collected on each wall of the excavation, and one composite sample collected from the excavation floor. With the exception of three locations (5-VS-125, 5-VS-126, and 38-VS-56 –see Figures in Appendix B), excavation proceeded in the hotspot areas until arsenic and lead concentrations met levels that could be placed within GC Area PAs. The excavation depth of each hotspot location varied, and ranged from a total excavation depth of one foot to eight and a half feet. Locations 5-VS-125 and 5-VS-126 had arsenic concentrations greater than 530 mg/kg and were designated as MSU-96 and MSU-97, respectively, and were addressed during final Site remediation. Both of these MSUs were located in GC-01. Remediation of these MSUs is described in detail in Appendix D. Location 38-VS-56 also had an arsenic concentration greater than 530 mg/kg, and was removed during the 2001 Hotspot IRA, described in the following section.

  Hotspot soil were excavated and stockpiled for future treatment at the on-Site screening plant, and for subsequent disposal in an Ecology-approved off-Site landfill. After the hotspot concentrations were removed, these areas were either incorporated into a GC Area PA, where no additional excavation was needed, or became part of the Large-Scale Excavation area for GC Area non-PAs, where excavation was completed until soil concentrations met the RLs and the SL for the GC Area non-PAs.

  Complete documentation of this IRA is contained in the *Hotspot Interim Action Report, Former DuPont Works Site, DuPont, Washington, October 4, 2000* memorandum presented in Appendix C. Documentation of the treatment process for the soil excavated during this IRA is contained in the *Interim Source Removal Actions: Screening Plant Report, January 22, 2002* memorandum presented in Appendix C.

- 2001 Hotspot IRA: The purpose of this excavation was to remove a hotspot area of arsenic-

contaminated soil identified in Area 38 (location 38-VS-56, with a concentration of 970 mg/kg, shown on a map in the associated report in Appendix C), which remained after completion of 2000 Hotspot IRA. Soil was excavated to a depth of two feet, extending 25 feet out to the north, south, east, and west of this location. Following excavation, three verification samples were collected, one from each wall of the excavation (there were only three sides to this excavation due to an adjacent excavation) and one five-point composite sample from the floor of the excavation. Confirmation samples indicated that all measured arsenic concentrations were below the GC Area PA arsenic RL of 530 mg/kg. This location was included in a GC Area PA.

The excavated soil was stockpiled for future treatment at the on-Site screening plant and for subsequent disposal in an Ecology-approved off-Site landfill. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hotspots, April 22, 2002* memorandum presented in Appendix C. Documentation of the treatment process for the soil excavated during this IRA is contained in the *Interim Source Removal Actions: Screening Plant Report, January 22, 2002* memorandum presented in Appendix C.

3.2.5 Sand Laydown Areas Excavation

The purpose of this IRA was to excavate arsenic and lead impacted soil to provide clean areas for sand storage. The sand was needed to construct the final capping layer of the GC Area PAs. In this IRA, soil was excavated to a depth of one and a half feet within each of two areas staked for sand storage in the GC Area RUs. Following excavation, one discrete confirmation soil sample was collected within each grid node of a 50-foot sampling grid. Sample results for each storage area were combined for comparison to the MTCA three-fold criteria for establishing compliance with the applicable RL for arsenic and the SL for lead. To meet the MTCA three-fold criteria: the 95% UCL concentration of all samples had to be lower than the RL or SL; no more than 10 percent of the samples could have a concentration greater than the RL or SL; and no samples could have a concentration greater than two times the RL or SL. All sand laydown areas met these criteria.

The soil excavated during this IRA was placed in a GC Area PA. Complete documentation of this IRA is contained in the *Sand Laydown Area Interim Action Report, Former DuPont Works Site, DuPont Washington, November 16, 2000* memorandum presented in Appendix C.

3.2.6 Storm Water Pipeline Area Excavation

The purpose of this excavation was to remove soil having arsenic and lead concentrations over the arsenic RL of 60 mg/kg and the lead SL of 118 mg/kg, respectively, around the area where a storm water runoff overflow pipe was to be installed.

In the storm water runoff overflow pipeline area, one foot of soil was excavated within an approximate 50-foot by 25-foot box surrounding each of the pipeline sample locations. A five-point composite verification sample was collected from the bottom of each excavation at a depth of zero to six inches and was analyzed for arsenic and lead. After the initial round of excavation, all but two sample locations met

the Site-specific RL and SL. In the two locations where arsenic concentrations were 109 mg/kg and 80 mg/kg, one additional foot of soil was removed. When the locations were re-sampled, both had arsenic concentrations below the RL.

The soil excavated during this IRA was placed in a GC Area PA. Complete documentation of this IRA is contained in the *Perimeter Soil and Storm Water Runoff Overflow Pipeline Interim Corrective Action, November 2002* memorandum presented in Appendix C.

3.2.7 On-Site Stockpile Excavations

The purpose of this IRA was to characterize and designate the appropriate disposal option for 164 stockpiles of soil and/or debris located across the Site. These stockpiles were created as a result of IRAs conducted between 1991 and 1995. Based on characterization of the stockpiled materials, 14 stockpiles were identified for direct off-Site disposal, seven stockpiles were identified for screening followed by off-Site disposal, 139 stockpiles were identified for placement in the GC Area PAs, and four stockpiles were identified for use as general fill.

Complete documentation of this IRA is contained in the *Interim Source Removal Actions: On-Site Stockpiles Report at the Former DuPont Works Site, January 28, 2002* memorandum presented in Appendix C. Documentation of the treatment process for the seven stockpiles identified for screening and off-Site disposal is contained in the *Interim Source Removal Actions: Screening Plant Report, January 22, 2002* memorandum presented in Appendix C.

3.3 Miscellaneous Small Units (MSUs)

The MSUs within the GC Area RUs included debris piles, foundations, sections of the NGRR, and other localized areas with soil concentrations of arsenic, copper, lead, Bunker-C fuel oil, motor oil, 2,4-DNT, 2,6-DNT, tetrachloroethene, and/or TNT that were elevated over GC Area non-PA CLs, RLs, or the SL. The MSUs, their associated constituents, and the GC Area RU where they were located are presented in Table 3-2. Following the remediation completed in 2005, the remaining constituent concentrations met the applicable CLs, RLs, and SL. The remedial action completed for each MSU is discussed in Appendix D.

3.4 Tree Root Zone Remediation

There were over 300 trees within the GC Area RUs that were part of the Tree Root Zone Remediation program. Trees were selected for remediation based on the desire to preserve large trees within the GC Area and to create a buffer along the eastern perimeter of the Site. The locations of Tree Root Zone Remediation Areas within the GC Area RUs are shown in Figure 3-3.

Tree Root Zone Remediation involved sampling within tree drip lines (i.e., the approximate horizontal distance of the outstretched limbs and roots) for arsenic and lead. Where the arsenic RL or lead SL were exceeded, one foot of soil was carefully removed within the drip line of the tree, soil samples were collected, and the excavation was immediately filled with clean topsoil. If confirmation sample results exceeded the remediation goals, additional rounds of excavation and confirmation sampling were

conducted until the remediation goals were achieved. The remaining arsenic and lead soil concentrations met the arsenic RL of 60 mg/kg and the lead SL of 118 mg/kg around all trees that were left in place. The Tree Root Zone Remediation program is presented in Appendix E.

3.5 Large-Scale Excavation

Large-scale excavation of arsenic and lead contaminated soil was the primary type of remediation conducted in the non-PAs of the GC Area RUs. The Large-Scale Excavation Areas within the GC Area RUs are shown in Figure 3-4. Large-scale excavation consisted of the following steps:

- The boundaries for the Large-Scale Excavation were identified based on previous excavation boundaries, the consent decree boundary, or future land-use boundaries using a GPS. The tolerance of the GPS is 8/100 of a foot on the horizontal axis.
- All trees were cleared from the area (with the exception of approximately 300 trees chosen for preservation).
- Any remaining vegetation was removed.
- A GPS was used to determine the elevation on a 75-foot grid before any excavation took place. The tolerance of the GPS is 5/100 of a foot on the vertical axis. Elevations were determined at all grid-sampling locations.
- Excavators and off-road trucks were used to remove one foot of soil that was then placed in the GC Area PAs.
- The GPS was used to confirm that at least one foot of soil was removed from grid locations. If one foot of soil was not removed from a grid location, then additional excavation was done for the area until at least one foot of soil was removed.

Following the excavation of this soil, the remaining surface soil (zero to six inches) were sampled, with one five-point composite sample collected within each 75-foot grid area. If sampling results indicated that constituent concentrations were below applicable GC Area RLs and SL, the remediation was considered complete. If constituent concentrations were found to be above the GC Area RLs or the SL, excavation activities were repeated in one-foot increments until the RLs and the SL were met for the grid location.

Approximately 800 grid sample locations were established to complete the large-scale remediation in the GC Area non-PAs. Of these sample locations, 32 required a second round of excavation and three required a third round of excavation to meet the associated remediation goals.

3.6 Placement Area Cap Construction

Following the placement of contaminated soil, the PAs were covered with an engineered cap. The cap was constructed to be a minimum of 18 inches thick and consisted of two layers:

- An ecological cap (ecocap) to protect ecological receptors

- A human health cap that (combined with the ecocap) prevents humans from coming into contact with the contaminated soil

The ecocap consisted of at least 12 inches of low organic content Steilacoom gravel that was excavated on Site. The ecocap is an exposure barrier that will eliminate the possibility of animals coming into contact with PA soil or associated soil biota. The lack of organic content in the Steilacoom gravel makes it an unsuitable environment for soil biota. The ecocap was placed directly on top of the contaminated soil. Scrapers or trucks were used to transport the gravel to the PA, then a bulldozer was used to spread the gravel and a roller was used for compaction. A GPS survey was performed before and after the gravel was placed to ensure that a minimum of 12 inches of compacted gravel was placed over all of the contaminated soil. Once the ecocap was complete, the PA boundary and topographical elevations were surveyed, and a legal description was developed. This information is presented in Appendix F.

The second layer of the cap was the human health cap, which consisted of a minimum of six inches of clean soil, placed directly on top of the ecocap. The soil used to construct the human health cap varied in composition, but met all Ecology standards for "clean material." The majority of the soil used was topsoil obtained from off-Site sources and oversized sands purchased off Site. Off-road trucks were used to transport the majority of this soil to the PA for placement. A bulldozer was used to spread it to an initial depth of six inches over the ecocap. A GPS survey was performed before and after the soil was placed to ensure that a minimum of six inches of soil was placed over all of the ecocap. Additional soil was added until the depth of the human health and ecocap were greater than 18 inches. Once this thickness was reached, the GPS was used to survey the final contours of the cap. As-built documentation of the cap construction is presented in Appendix F.

3.7 Golf Course Construction

Following remediation activities, GC construction began in the areas contained within the GC footprint (i.e., the PA and non-PA areas). The PAs were built so that the final contours were consistent with the GC design contours and GC construction could be completed without having to dig into the ecocap or human health cap. Additional contouring of the GC Area PA was completed by adding more soil to the human health cap, and then grading that material.

In general, construction of the GC involved installation of drainage and irrigation systems, the addition of sand topsoil material, rough shaping of the formation of all GC contours and features (i.e., fairways, roughs, tees, greens, and sand bunkers), construction of cart paths, final grading, and seeding of the GC. In a few cases it was necessary to install drain-pipes in PAs. In those cases, the excavated material was placed in an uncompleted PA and the trench was backfilled with clean pipe bedding. As-built documentation of the GC construction is presented in Appendix F.

3.8 Summary of Remedial Actions in the Golf Course Area

The remedial actions described in this section were completed within the eight GC Area RUs to remove elevated levels of metals (i.e., arsenic, copper, and lead), explosives (i.e., 2,4-DNT, 2,6-DNT, nitrobenzene, and TNT), Bunker-C fuel oil, motor oil, and tetrachloroethene. Confirmation soil sampling results documenting the constituent concentrations that remain in place (i.e., those concentrations that met

the applicable CLs, RLs and the SL) are presented in Appendix B. These data document the successful completion of remedial activities in the GC Area RUs, and that these activities were completed in a manner consistent with the CAP established by Ecology (Ecology, 2003). In addition, Appendix F presents the data and As-builts that demonstrate that the ecocap and human health cap were constructed in a manner that met the design requirements identified in the CAP.

Table 3-1 – Soil Cleanup Levels, Remediation Levels, and the Screening Level Used for Evaluating Golf Course Non-Placement Area and Placement Area Land Uses

Constituent	Non-Placement Area Cleanup Goals (mg/kg)	Placement Area Cleanup Goals (mg/kg)	Source
Explosives			
Total Dinitrotoluene	3.0	3.0	Cleanup Level; based on Ecology Agreement (Ecology letter from Mike Blum to Jim Odendahl and Ron Buchanan, January 11, 2001). Total of 2,4-dinitrotoluene and 2,6-dinitrotoluene concentrations.
Nitrobenzene	0.051	0.05	Cleanup Level; the MTCA Method B Value protective of Groundwater. The derivation of this value is presented in WAC 173-340-740.
2,4,6-Trinitrotoluene	1.75	1.75	Cleanup Level; based on Ecology Agreement (Ecology letter from Mike Blum to Jim Odendahl and Ron Buchanan, January 11, 2001).
Petroleum Hydrocarbons			
Motor Oil (Bunker C)	7,600	7,600	Cleanup Level; based on Ecology Agreement (PIONEER Technologies Corporation. 2002. Human Health and Ecological Risk Assessment for the Former DuPont Works Site, DuPont, Washington, Appendix C)
Motor Oil	2,000	2,000	Cleanup Level; the MTCA Method A Table Value (173-340-745 WAC).
Inorganics			
Arsenic	60	530	Remediation Level; based on Ecology Agreement (Ecology letter from Mike Blum to Vern Moore and Izzy Zanikos, June 25, 1999).
Copper	263	263	Cleanup Level; the MTCA Method B Value protective of Groundwater. The derivation of this value is presented in WAC 173-340-740.
Lead	118	4,100	Golf Course Area: Screening Level; based on Ecology-derived soil screening value for protection of terrestrial ecological receptors (WAC 173-340-7493) Placement Area: Remediation Level; based on Ecology Agreement (Ecology letter from Mike Blum to Vern Moore and Izzy Zanikos, May 3, 1999).
Mercury	24	24	Cleanup Level; based on Ecology Agreement (Ecology letter from Mike Blum to Vern Moore, Linda Rudisell, and Jack Frazier, August 12, 1993)
Volatile Organics			
Tetrachloroethene	0.0091	0.0091	Cleanup Level; the MTCA Method B Value protective of Groundwater. The derivation of this value is presented in WAC 173-340-740.

SECTION 4 – INDUSTRIAL AREA

4.1 Introduction

A portion of the area north of Sequalitchew Creek will be used for industrial purposes as well as OS (see Figure 4-1). Industrial use may include activities ranging from mining gravel to development of industrial facilities. The IN Area occupies 35.7 acres.

Remediation completed within the IN Area included:

- IRAs
- MSU remediation

The IN Area is shown in Figure 4-1, and the associated CLs for the IN Area are shown in Table 4-1. Following completion of all soil removal remedial actions, the soil in the IN Area met the CLs. Results of all confirmation soil sampling completed in the IN Area, which identify the soil constituent concentrations left in place following remediation, are presented in Appendix B.

4.2 Interim Remedial Actions

IRAs were conducted in the Industrial Area between 1999 and 2001, and included excavation of soil in hotspots, where there were elevated concentrations of arsenic, lead, 2,4-DNT, 2,6-DNT, and TNT. The locations of IRA areas within the IN Area are shown in Figure 4-2. The 2000 and 2001 IRAs are described below.

4.2.1 Hotspot Areas Excavations

Two separate IRAs were completed for the hotspot areas within the Industrial Area. One IRA was completed in 2000 and the other IRA was completed in 2001. These IRAs are described in the following paragraphs.

- 2000 Hotspot IRA: The purpose of this IRA was to remove soil hotspot areas of arsenic, lead, and TNT identified in RI sampling events in order to achieve compliance with the IN Area CLs. The area and depth of excavation varied, depending on the size and location of the hotspot area. This program resulted in excavation of three areas based on elevated concentrations of arsenic and/or lead and one area based on elevated concentrations of TNT. Following each round of excavation, five samples were collected within each 50-foot by 50-foot excavation. This included four samples collected on each wall of the excavation, and one composite sample collected from the excavation floor.
  - The data for each of the four excavations and the remaining area were compared to the IN Area CLs of 90 mg/kg for arsenic, 1,000 mg/kg for lead, and 1.75 mg/kg for TNT. The area excavated for elevated TNT concentrations (Area 10, identified on a map in the associated report in Appendix C) met the CL following the initial excavation. At

Ecology's suggestion, arsenic and lead data from the remaining three areas were grouped in the following manner:

- Hotspot data outside each excavation (i.e., samples out 25 feet from the perimeter of the excavation) were grouped together to demonstrate that the lateral extent of each excavation was in compliance with the CLs.
- Samples inside each excavation were grouped together to demonstrate that the vertical extent of each excavation was in compliance with CLs.

- After grouping the sampling results in accordance with Ecology's suggestion, the three excavations, as well as the IN Area as a whole, were in compliance with the MTCA three-fold criteria for IN Area CLs. To meet the MTCA three-fold criteria the 95% UCL concentration of all samples had to be lower than the CLs, no more than 10 percent of the samples could have a concentration greater than the CLs, and no samples could have a concentration greater than two times the CL.
- All excavated soil with arsenic and lead contamination was placed in GC Area PAs, and all TNT-contaminated soil was stockpiled for off-Site disposal.

Complete documentation of this IRA is contained in the *Hotspot Interim Action Report, Former DuPont Works Site, DuPont, Washington, October 4, 2000* memorandum presented in Appendix C.

- 2001 Hotspot IRA: The purpose of this IRA was to remove soil concentrations of 2,4-DNT, 2,6-DNT, and/or TNT that were elevated above the IN Area CLs. The area and depth of excavation varied, depending on the size and location of the hotspot area.
  - The 2,4-DNT, 2,6-DNT, and/or TNT hotspot area included in this IRA was located in former Area 10, in the northern portion of the Industrial Area. Soil was excavated to a depth of three feet, and extended 15 feet out to the north, south, east, and west of the location of the elevated concentration. Following excavation, five verification samples were collected; one from each wall of the excavation, and one five-point composite from the floor of the excavation. These confirmation samples indicated that the remaining concentrations of 2,4-DNT, 2,6-DNT, and TNT were below the Industrial Area CLs.
  - All 2,4-DNT, 2,6-DNT, and TNT contaminated soil was stockpiled for off-Site disposal in an Ecology-approved landfill.

  Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hotspots, April 22, 2002* memorandum presented in Appendix C.

4.3 Miscellaneous Small Units

There were two MSUs within the IN Area, and both had localized areas with soil concentrations of nitrobenzene that were elevated over IN Area CLs. Following remediation, nitrobenzene concentrations

met the CLs. The remedial action completed for each MSU is discussed in Appendix D.

4.4 Summary of Remedial Actions in the Industrial Area

Remedial actions completed in the IN Area consisted of IRAs completed between 1999 and 2001 to remove elevated levels of arsenic, lead, 2,4-DNT, 2,6-DNT, nitrobenzene, and TNT in the IN Area. Confirmation soil sampling results documenting the constituent concentrations that remain in place (i.e., those concentrations that met the CLs) are presented in Appendix B. The IN Area is in compliance with the CLs approved by Ecology and this area is now ready for development for industrial uses.

Table 4-1 – Soil Cleanup Levels Used for Evaluating Industrial Land Use

Constituent	Cleanup Goals (mg/kg)	Source
Explosives		
Dinitrotoluene - Total	3.0	Cleanup Level; based on Ecology Agreement (Ecology letter from Mike Blum to Jim Odendahl and Ron Buchanan, January 11, 2001). Total of 2,4-dinitrotoluene and 2,6-dinitrotoluene concentrations.
Nitrobenzene	0.051	Cleanup Level; the MTCA Method B Value protective of Groundwater. The derivation of this value is presented in WAC 173-340-740.
2,4,6-Trinitrotoluene (TNT)	1.75	Cleanup Level; based on Ecology Agreement (Ecology letter from Mike Blum to Jim Odendahl and Ron Buchanan, January 11, 2001).
Inorganics		
Arsenic	90	Cleanup Level, the MTCA Method C Industrial Level (Ecology letter from Mike Blum to Vern Moore and Izzy Zanikos, June 25, 1999).
Lead	1,000	Cleanup Level; based on the MTCA Method C Industrial Level (Letter from Mike Blum to Vern Moore and Izzy Zanikos, May 3, 1999).

SECTION 5 - HISTORICAL AREAS

5.1 Introduction

Four HI Areas (HI) have been identified on the Site, including the 1833 Fort Nisqually Site (Historical Site Number 45-PI-55), the Fort Nisqually Cemetery (Historical Site Number 45-PI-404), the Shell Midden (Historical Site Number 45-PI-72), and an area where Native American Graves were found (Historical Site Number 45-PI-712). In total, the HI Areas consist of approximately six acres. Each of these HI Areas was designated as a separate RU. The 1833 Fort Nisqually Site is identified in this report as HI Area RU HI-01; the Fort Nisqually Cemetery is identified as HI Area RU HI-02; the Native American Graves area is identified as HI Area RU HI-03; and the Shell Midden area is identified as HI Area RU HI-04

The location of the HI Area RUs is presented in Figure 5-1. A brief description of each of these areas is presented in the following paragraphs. Detailed descriptions are presented in the archeological reports provided in Appendix A.

Remedial actions completed in the HI Areas included:

- MSU remediation
- Capping

Minimal remediation was done in the HI Area RUs to ensure the preservation of the historical artifacts. All work was completed under the direction/supervision of HRA, the Nisqually Tribe and the DAHP. The applicable CL, RL, and SL identified for the HI Areas are shown in Table 5-1.

5.1.1 1833 Fort Nisqually Site (45PI55)

The 1833 Fort Nisqually Site is located to the west of Sequalitchew Creek, between the creek and Old Fort Lake. The 1833 Fort included a store, a kitchen, the Chief Factor's House, a dwelling house for the men, an Indian hall, stables, and agricultural buildings such as cellars and sheds. Following the listing of this Fort on the National Register in 1974, excavations uncovered the bases of posts used to support the palisades, which were enclosures established around the Fort. During remediation, a 63-foot buffer was established around the outline of the Fort's palisade, and this area was designated as a "protected area." Remediation activities included the excavation of two small areas to remove elevated lead concentrations. To preserve surface artifacts that were present, no additional soil excavation was done.

5.1.2 Fort Nisqually Cemetery (45PI404)

The Fort Nisqually Cemetery is located east of 1833 Fort Nisqually. It was inadvertently discovered in 1987 when skeletal remains were uncovered during construction work. A protective buffer was placed around the Cemetery to avoid damage during soil remediation activities. Soil remediation activities in this area involved the placement of a protective soil cap.

5.1.3 Shell Midden (45PI72)

The Shell Midden is located in the far southwest corner of the Site. About one-third of the Shell Midden is located within the Site, in a bluff-edge green belt area; the remainder lies outside the Consent Decree Area fence line. Historical investigations have confirmed the presence of extensive Shell Midden deposits, faunal remains, and stone tools. A buffer of 50 feet was established around the portion of the Shell Midden that is located within the Site. Soil remediation activities in this area involved the removal of trees growing on the Shell Midden and the placement of a protective soil cap.

5.1.4 Native American Graves (45PI712)

The Native American Graves are located near the eastern Site boundary. This area was discovered in January 2003 after heavy rains fell on a scraped area, revealing two pieces of human bone. Soil remediation activities in this area involved the placement of a protective soil cap. Miscellaneous Small Units

These MSUs located within the HI Area RUs included localized areas with soil concentrations of aldrin, arsenic, and lead that were elevated over the HI Area CL, RL, and SL. The MSUs, their associated constituents, and the HI Area RU where they are located are presented in Table 5-2. Following remediation, remaining constituent concentrations met the applicable CL, RL, and SL, or the area was capped. The remedial action completed for each MSU is discussed in Appendix D.

5.2 Historical Areas Cap Construction

Remediation of HI Area RUs HI-02, HI-03, and HI-04 included the placement of a cap to protect archeological artifacts and to be an exposure barrier. The cap was constructed to be a minimum of 18 inches thick and consisted of two layers:

- An ecocap to protect ecological receptors.
- A human health cap that (combined with the ecocap) prevents humans from coming into contact with the contaminated soil.

The cap for HI-04 was constructed to eliminate the potential for disturbing artifacts. Initially, a road was built by placing gravel over the contaminated soil. Then, any heavy equipment that was used in the process of logging and vegetation removal stayed on the newly built road. The cap was constructed along the road through the addition of more gravel and then soil.

The ecocaps for HI Area RUs HI-02 and HI-03 consisted of 12 inches of Steilacoom gravel that was excavated from the Site. The ecocap was placed directly on top of the contaminated soil. The second layer of the cap was the human health cap, which consisted of six inches of clean soil, placed directly on top of the ecocap. The soil used to construct the human health cap varied in composition, but met all Ecology standards for "clean material." The majority of the soil used was topsoil obtained from off-Site sources, and oversized sand purchased off Site. After the minimal cap thickness was met, where planting was specified, additional soil was added to the depth necessary to cover the root ball of the designated

plant.

5.3 Summary of Remedial Actions in the Historical Areas

The remedial actions completed in the HI Areas included MSU excavations of lead contaminated soil in HI Area RU HI-01, and capping in the remaining three HI Areas. The constituents that were present above the applicable CL, RL, and SL were aldrin, arsenic, and lead. Soil sampling results documenting the constituent concentrations that remain in place are presented in Appendix B. Soil concentrations of arsenic and lead in HI-02, HI-03, and HI-04 were higher than the CL, RL, or SL in some instances, however a cap was placed over these areas to prevent exposure to human and ecological receptors. Therefore, the remedial objectives identified in the CAP established by Ecology (Ecology, 2003), were met in all HI Areas.

Table 5-1 – Soil Cleanup Level, Remediation Level, and Screening Level Used for Evaluating Historical Areas

Constituent	Cleanup Goal (mg/kg)	Source
Inorganics		
Arsenic	32	Cleanup Level; Value is site-specific background level for arsenic. Ecology Agreement (Ecology letter from Mike Blum to Vern Moore and Izzy Zanikos, June 25, 1999)
Lead	118	Screening Level; Ecology-derived soil screening value for protection of terrestrial ecological receptors (WAC 173-340-7493)
Pesticides/PCBs		
Aldrin	0.005	Cleanup Level; the MTCA Method B Value protective of Groundwater. The derivation of this value is presented in WAC 173-340-740.

Table 5-2 – Miscellaneous Small Units in Historical Areas

HI – Historical Area
MSU – Miscellaneous Small Unit
NGRR – Narrow Gauge Railroad
RU – Remediation Unit

SECTION 6 – OPEN SPACE AREAS

6.1 Introduction

Four areas of the Site were designated for use as OS (see Figure 6-1). The OS Areas comprise approximately 72.2 acres. The OS Areas border Sequalitchew Creek to the north and south, and surround Old Fort Lake.

Remediation completed within the OS Area included:

- IRAs
- MSU remediation
- Tree remediation
- Large-Scale Excavation

Minimal Large-Scale Excavation was conducted in the OS Area due to the sensitive nature of the areas, and the overriding goal of trying to protect ecological habitat.

The CL and SL identified for the OS Area RUs are shown in Table 6-1. Following completion of the remedial actions, the soil in all of the OS Area RUs met the applicable CL and RL. Results of all confirmation soil sampling completed in the OS Area, which identify the soil constituent concentrations left in place following remediation, are presented in Appendix B.

6.2 Interim Remedial Actions

IRAs were conducted in the OS Area between 1999 and 2001, and included the excavation of soil along the NGRR, and along the storm water pipeline excavation. The locations of IRA areas within the OS Area are shown in Figure 6-2. Each of these actions is described briefly below.

6.2.1 NGRR Excavation

The purpose of this excavation was to remove elevated arsenic concentrations found associated with the NGRR located along Sequalitchew Creek, where an arsenic-containing herbicide was historically used for weed control. In this IRA, one and a half feet of soil were excavated within 25 feet of the centerline of the NGRR. Some NGRR was not excavated due to the close proximity of timber that was identified for future harvesting. All remaining NGRR were designated as MSUs (i.e., NGRR MSUs) and excavation was done as part of the final remediation (see Appendix D). Following excavation, one five-point composite confirmation sample was collected from the excavation floor every 50 feet along the NGRR. After two rounds of excavation, there were still five locations (LR-68-0-02, LR-68-74-02, LR-68-525E-02, LR-68-600E-02, and LR-68-1575E-02, identified on a map in the associated report in Appendix C) where the arsenic CL of 32 mg/kg was not met. These locations were incorporated into the OS Area RUs identified for Large-Scale Excavation, and were excavated during final Site remediation.

The soil excavated during this IRA was placed in one of the GC Area PAs. Complete documentation of this IRA is contained in the *Interim Corrective Action Report, Foundations, Narrow Gauge Railroad, and Hotspots, April 22, 2002* memorandum presented in Appendix C.

6.2.2 Storm Water Pipeline Excavation

The purpose of this excavation was to remove soil having arsenic and lead concentrations over the arsenic CL of 32 mg/kg and the lead SL of 118 mg/kg, respectively, around the area where a storm water runoff overflow pipe was to be installed. For this IRA, one foot of soil was excavated within an approximate 50-foot by 25-foot box surrounding each of the pipeline sample locations. A five-point composite verification sample was collected from the bottom of each excavation at a depth of zero to six inches and analyzed for arsenic and lead. After excavation, all sample locations had arsenic concentrations below the CL.

The soil excavated during this IRA was placed in a GC Area PA. Complete documentation of this IRA is contained in the *Perimeter Soil and Storm Water Runoff Overflow Pipeline Interim Corrective Action, November 2002* memorandum presented in Appendix C.

6.3 Miscellaneous Small Units

The MSUs located within the OS Areas included one section of the NGRR, and other localized areas with elevated concentrations of arsenic and lead. The MSUs, associated constituents, and the OS Area where they were located are presented in Table 6-2. Following remediation, remaining constituent concentrations met the OS Area CL and SL except for four locations, two located in MSU-NGRR-48, and two located in MSU-NGRR-49. It was acceptable to leave these concentrations because these areas were covered with two feet of topsoil and will be paved with asphalt as part of a permanent walking trail that leads down to Puget Sound. The remedial action completed for each MSU and the confirmation sampling results are discussed in Appendix D.

6.4 Tree Root Zone Remediation

There were four trees within the OS Area RU OS-04 that were part of the Tree Root Zone Remediation. Trees were selected for remediation based on the desire to preserve vegetation on the Site where possible, and to create a buffer around the western perimeter of the Site. The locations of Tree Root Zone Remediation within the OS Area are shown in Figure 6-3.

Tree Root Zone Remediation involved sampling soil within tree drip lines (i.e., the approximate horizontal distance of the outstretched limbs and roots) for arsenic and lead. Where the arsenic CL or the lead SL were exceeded, one foot of soil was carefully removed within the drip line of the tree, soil samples were collected, and the excavation was immediately filled with clean topsoil. If the confirmation sample results exceeded the remediation goals, additional rounds of excavation and confirmation sampling were undertaken until the remediation goals were achieved. Of the four trees identified for the OS Area RU Tree Root Zone Remediation, three (i.e., T-188, T-189, and T-190) required one round of remediation, and the fourth tree did not require remediation.

Following remediation, remaining arsenic and lead concentrations met the arsenic CL of 32 mg/kg and

the lead SL of 118 mg/kg. The Tree Root Zone Remediation program is presented in Appendix E

6.5 Large-Scale Excavation

The Large-Scale Excavation within the OS Area RUs are shown in Figure 6-4. Large-Scale Excavation consisted of the following steps:

1. The boundaries for the Large-Scale Excavation were identified based on previous excavation boundaries, or future land-use boundaries using a GPS. The tolerance of the GPS is 8/100 of a foot on the horizontal axis.
2. All trees were cleared from the area (with the exception of trees chosen for preservation).
3. Any remaining vegetation was removed.
4. A GPS was used to determine the elevation on a 75-foot grid before any excavation took place. The tolerance of the GPS is 5/100 of a foot on the vertical axis. Elevations were determined at all grid sampling locations.
5. Excavators and off-road trucks were used to remove one foot of soil that was then placed in the GC Area PAs.
6. The GPS was used to confirm that at least one foot of soil was removed from grid locations. If one foot of soil had not been removed from a grid location, then additional excavation was done for the area.

Following the excavation of this soil, the remaining surface soil (zero to six inches) was sampled with one five-point composite sample collected within each 75-foot grid area. If sampling results indicated that constituent concentrations were below the applicable OS Area CL and SL, the remediation was considered complete. If constituent concentrations were found to be above the cleanup goals, excavation activities were repeated in one-foot increments until the cleanup goals were met for the grid location (i.e., the 75 foot by 75 foot box representing the sample location).

Twenty-eight sample locations were established to document completion of Large-Scale Excavation in the OS Area. Of these sample locations, three required a third round of excavation to meet the associated remediation goals.

6.6 Summary of Remedial Actions in the Open Space Areas

The remedial actions described in this section were completed within the OS Area to remove elevated levels of arsenic and lead. Confirmation soil sampling results representing the constituent concentrations that remain in place (i.e., those concentrations that met the CL and SL) are presented in Appendix B. These data document the successful completion of remedial activities in the OS Areas and provide evidence that these activities were completed in a manner consistent with the CAP established by Ecology (Ecology, 2003).

Table 6-1 – Soil Cleanup Level and Screening Level Used for Evaluating Open Space Land Use

Constituent	Cleanup Goal (mg/kg)	Source
Inorganics		
Arsenic	32	Cleanup Level; Value is site-specific background level for arsenic. Ecology Agreement (Ecology letter from Mike Blum to Vern Moore and Izzy Zanikos, June 25, 1999)
Lead	118	Screening Level; Ecology-derived soil screening value for protection of terrestrial ecological receptors (WAC 173-340-7493)

SECTION 7 – ON-GOING REQUIREMENTS

7.1 Groundwater

Groundwater monitoring is required at the Site until the total DNT groundwater concentration is below the practical quantitation limit (PQL) of 0.33 ug/l for four consecutive sampling rounds. Because the MTCA CL is lower than the PQL, Ecology defaults to the PQL as the CL until such time as technology advances, allowing detection of those constituents at lower concentrations. Testing for an isomer will be discontinued for a well if all individual DNT isomers are not detected for four consecutive sampling rounds. If only one isomer is detected in a well, then the single criterion (i.e., 32 ug/l for 2,4-DNT or 16 ug/l for 2,6-DNT) will be applied. Monitoring will be discontinued after approval from Ecology. The wells that will be monitored for DNT are monitoring well MW-19 and new monitoring wells DA-1, DA-2, DA-3, and DA-4. Current groundwater-monitoring locations are shown in Figure 7-1. The location of the GC boundary, including the GC Area PAs, are shown on this figure to provide spatial context for the monitoring well locations.

The highest DNT concentration in groundwater ever detected at the Site was 3.8 ug/L in MW-27 in January of 1995. However, DNT levels in this well declined below levels of concern in subsequent sampling rounds. This concentration was approximately 10 times higher than the PQL. If any of the results from future groundwater sampling are greater than 3.8 ug/L, Ecology will meet with the Companies to discuss the results.

7.2 Land-Use Restrictions

Intuitional controls, in the form of deed restrictions, will be placed upon the Site for perpetuity. These land-use restrictions will ensure that future development will be consistent with the goals of the cleanup, Ecology requirements, and the conditions and assumptions used to develop the Site-specific RLs. Site Deed Restrictions are presented in Appendix H.

7.3 Future Investigations

MTCA requires that Ecology conduct a review of the conditions and assumptions used to make their decisions on Project requirements at least every five years. This review and evaluation will be done to ensure that decisions made remain in compliance with state and federal law.

SECTION 8 – HEALTH AND SAFETY

8.1 Introduction

A safety policy was established for this remediation project, along with project-specific Health and Safety Plans (HASPs) developed by individual contractors. The safety policy outlined the safety requirements for all companies that participated in remediation activities at the Site. This policy was developed to assure the long-term safety of workers. In addition to the guidelines and procedures listed in the safety policy, the Site has an active health and safety program that meets Washington Industrial Safety and Health Act (WISHA) requirements and regulations. The program included requirements for a written HASP for each contractor working at the Site, including provisions for air monitoring to protect Site workers from unsafe working conditions. In addition to air monitoring, dust-prevention measures and perimeter dust monitoring was instituted during excavation work done within 500 feet of the Site boundary, to ensure that there were no off-Site impacts.

Key points from the safety policy included the following:

- Safety is the single most important factor in the work place. No work will be done on the Site except under the highest safety standards. At a minimum, this means following the rules and restrictions imposed by WISHA, the Occupational Safety and Health Administration (OSHA) and Weyerhaeuser and DuPont Company Safety Policies.
- Safety is a condition of employment. All contractors and employees must realize that the practice of unsafe work habits will result in immediate removal from the Site.
- The Project's goal is no incidents, accidents or loss of workdays. All accidents are preventable. As such, all Site contractors and employees will look for and report unsafe working conditions and personnel to the Project Management Team (PMT) as soon as possible.
- Safety procedures must apply to all contractors and workers. All contractors working on the Site have the potential to impact each other. As such, everyone working on the Site must follow the same procedures and precautions.
- All activities will follow Weyerhaeuser and DuPont Policies and Procedures. This will include Weyerhaeuser's Incident Investigations Program.
- All field or construction activities will be audited on a regular basis. Annual audits will be conducted by an independent or company auditor. DuPont company representatives will perform periodic audits.
- A safety briefing and debriefing will be held at the start and completion of each phase of the Project. A safety kickoff meeting will be held at the start of each activity. A debriefing will be held at the completion of each activity.
- A safety meeting will be held at the start of each workday. The safety meeting held at the start of each workday will provide the opportunity to discuss the work to be completed that day, any specific safety issues associated with that work and any observations or safety issues noted during the previous workday.

- Safety is the responsibility of each employee and contractor. All workers on Site must share in making the Site a safe work environment.
- Each Contractor is responsible for the health and safety of his/her employees. The PMT and Project Manager/Site Supervisor (PM/SS) will aid in the development of general guidelines but will not oversee the implementation of any health and safety program other than their own.
- Contractors are directly responsible for their subcontractors. The PMT will assess the safety performance of all contractors, not only by their actions, but by those of their subcontractors as well.

The HASP and air monitoring programs designed for both worker safety and prevention of off-Site dust migration are discussed in the following sections.

8.2 Site Health and Safety Plan

In accordance with the Site Health and Safety Policy, the contractors performing work at the Site prepared individual HASPs. These HASPs identified potential Site hazards, safe work practices, and emergency procedures. HASPs were prepared for IRAs (2001 and 2002), and final Site remediation (2003). A key component of the HASPs was air monitoring, which was the basis for determining the need for upgraded personal protective equipment and engineering controls. The air monitoring approach and results of this monitoring are presented in the following section.

8.3 Air Monitoring For Worker Safety During Remediation

Remediation of the Site involved different phases of removal of contaminants, including IRAs, which occurred in 2001 and 2002, and the final Site remediation, which was initiated in 2003. Final air monitoring reports were prepared for each phase of Site remediation to document exposures to Site workers (PIONEER and WSNW, 2002; PIONEER and WSNW 2003a; PIONEER and WSNW, 2004a). These reports are presented in Appendix G.

The air monitoring approach for each phase of Site remediation was similar, and is summarized below. Following the summary of the air monitoring approach, sampling results from each phase of remediation are presented.

8.3.1 Air Monitoring Approach

To ensure that workers were not exposed to elevated levels of arsenic and lead, the primary contaminants in on-Site soil, an air monitoring plan was prepared and implemented during remediation activities. This plan included provisions for both personal air monitoring, where sampling filters were attached to individual workers and the filters were sent to a laboratory for analysis, and real-time air monitoring, where a field monitor is placed near workers for instantaneous measurement of airborne dust concentrations. Personal air samples were taken in the breathing zone of workers expected to have the highest potential for exposure, and real-time air samples were taken in areas adjacent to workers, where airborne particulate levels were expected to be highest. The workers were informed of the results of the air monitoring at daily health and safety meetings.

8.3.1.1 Personal Air Monitoring

Personal air samples were collected during the first week of excavation activities. Workers expected to receive the highest exposure were monitored during an entire work shift. Samples were collected in the breathing zone of workers, and were analyzed for arsenic and lead by an American Industrial Hygiene Association (AIHA)-accredited laboratory, using the OSHA Method 125. AIHA-accredited laboratories are preferred because these laboratories participate in extensive quality control and quality assurance procedures that are monitored by OSHA.

8.3.1.2 Real-Time Air Monitoring

Real-time air monitoring was conducted using a mini-ram (personalDataRAM™, model pDR-1000AN, Monitoring Instruments for the Environment, Inc.) in order to ensure that that the permissible exposure limits (PELs) for arsenic and lead would not be exceeded. The use of the mini-ram was initiated during the first week of field activities. The frequency of sampling was determined based on the readings, changes in work patterns, or changes in soil conditions that could potentially result in increased dust emissions.

Using the highest measured lead concentration for the Site, the associated mini-ram concentration that would result in exposure to lead at the PEL of 5.0 mg/m^3 was calculated. Based on this calculation, a mini-ram action level of 2.5 mg/m^3 was established as a trigger for initiating the need for additional engineering controls or upgraded personal protective equipment. This mini-ram concentration was also protective for exposure to arsenic due to the lower concentrations of arsenic on Site.

8.3.2 Air Monitoring Results

8.3.2.1 2001 Interim Source Removal Actions - Personal Air Monitoring Results

Arsenic and lead were not detected in any of the samples above the sample detection limits that ranged from 0.2 micrograms per cubic meter (ug/m^3) to 0.5 ug/m^3. This detection limit was well below the WISHA PEL of 500 ug/m^3 for arsenic and 50 ug/m^3 for lead.

8.3.2.2 2002 Interim Remedial Actions - Personal Air Monitoring Results

All arsenic and lead levels were well below the WISHA PEL of 500 ug/m^3 for arsenic and 50 ug/m^3 for lead. The highest detected arsenic level was 3.32 ug/m^3, and the highest detected lead concentration was 16.9 ug/m^3.

8.3.2.3 2003 Final Site Remediation - Personal Air Monitoring Results

All arsenic and lead levels were well below the WISHA PEL of 500 ug/m^3 for arsenic and 50 ug/m^3 for lead. The highest detected arsenic level was 10.0 ug/m^3, and the highest detected lead concentration was 23.9 ug/m^3.

8.3.2.4 2001 Interim Source Removal Actions - Real-Time Air Monitoring Results

During periods of heavy equipment operation and times of maximum soil disturbance, continuous

particulate readings were taken adjacent to the worker assumed to have the maximum exposure. This person was chosen as the ground worker who directed the excavator operator. At no time were air concentrations above the 2.5 mg/m^3 action level. The maximum-recorded reading was 1.312 mg/m^3.

8.3.2.5 2002 Interim Remedial Actions - Real-Time Air Monitoring Results

During periods of heavy equipment operation and times of maximum soil disturbance, continuous particulate readings were taken next to workers expected to have the potential for maximum exposure. Workers chosen for monitoring included Heavy Equipment Operators, Archeologists and Ground People working adjacent to heavy equipment. There were three instances where the average air concentrations were above the 2.5 mg/m^3 action level. When these results were noted, additional soil wetting was implemented to reduce airborne dust levels. All average air concentrations were below the PEL of 5.0. The maximum average concentration was 3.47 mg/m^3.

8.3.2.6 2003 Final Site Remediation - Real-Time Air Monitoring Results

During periods of heavy equipment operation and times of maximum soil disturbance, continuous particulate readings were taken next to workers expected to have the potential for maximum exposure. Workers chosen for monitoring included Heavy Equipment Operators, Archeologists and Ground People working adjacent to heavy equipment. There were no instances where the average air concentrations were above the 2.5 mg/m^3 action level. The maximum average concentration was 1.39 mg/m^3.

8.4 Perimeter Air Monitoring for Off-Site Particulate Emissions

Perimeter air monitoring involved measurement of respirable particulate matter (PM_{10}) on Site, along the property fence line, to serve as a worst-case surrogate for particulate levels that may migrate off Site. The purpose of the PM_{10} sampling was to document the effectiveness of engineering controls in limiting off-Site migration of particulate during on-Site excavation and remediation work.

PM_{10} sampling was done during perimeter soil excavation conducted at the Site between June 19 and July 12, 2002, and between September 2 and November 14, 2003. Final perimeter PM_{10} air monitoring reports were prepared for both sampling periods (PIONEER and WSNW, 2003b; PIONEER and WSNW, 2004b). These reports are presented in Appendix G. The PM_{10} sampling approach for each phase of the perimeter soil excavation was similar, and is summarized below. Following the summary of the PM_{10} sampling approach, sampling results from each phase of PM_{10} sampling are presented.

8.4.1 PM_{10} Sampling Approach

Sampling for PM_{10} was conducted using Hi-Volume particulate samplers (GMW Model IP 10-8000 PM PM_{10}). PM_{10} samplers were set up along the south fence on the Site boundary, approximately 250 feet apart. Samplers were located directly adjacent to excavation activities to enable measurement of "worst case" particulate levels. Samplers were moved regularly to stay adjacent to the excavation activities as they progressed along the Site boundary. Depending on the size of the area to be excavated, three to four PM_{10} samplers were set up each day during excavation activities. Samples were collected on a 24-hour basis. The sample filters were removed daily and sent for analysis of PM_{10}, arsenic, and lead.

8.4.2 PM_{10} Sampling Results

During both the 2002 and 2003 sampling periods, all PM_{10}, arsenic, and lead levels were below health-based concentrations established to be protective of residential exposures. Based on the 2002 PM_{10} sampling results, and an evaluation of the wind speed and direction during the sampling period and other typical time periods, the following conclusions were made:

- The engineering controls used during the perimeter interim corrective action were successful in limiting off-Site particulate transport.
- The location of the excavation activities, as well as the wind speed and direction during the sampling period, could be considered a "worst case" scenario. Therefore it is unlikely that future excavation work would result in off-Site particulate levels that are of concern.
- The results from this program indicate negligible impacts to surrounding property from Site dust even under "worst case" conditions.

During the 2002 sampling event, the highest concentration of lead (0.019 parts-per-billion [ppb], 2003) was an order of magnitude below the health-based concentration (1.5 ppb). The highest concentration of arsenic (0.011 ppb, 2002) was below the health-based concentration of 0.017 ppb. Arsenic and lead were not detected in any samples collected during the 2003 sampling event.

FORMER DUPONT WORKS SITE ARCHAEOLOGICAL CORRESPONDENCE

CORRESPONDENCE.PDF

Description of Contents of Correspondence.pdf
▪ Transmittal to Stephenie Kramer, WA OAHP, re: 2003-2004 Monitoring Report
▪ Transmittal to Roxanne Woodruff, Descendants of Fort Nisqually Employees Association, re: Report on Treatment of Human Remains at 45PI712
▪ Transmittal to Stephenie Kramer, WA OAHP, re: archaeological testing reports 45PI712, 45PI576, 45PI713, 45PI55
▪ Transmittal to John Simmons, Nisqually Indian Tribe, and Dr. Allyson Brooks, WA OAHP, re: Report on Archaeological Testing at 45PI713
▪ Notification to Dr. Allyson Brooks, WA OAHP, and The Honorable Larry Sanchez, Nisqually Indian Tribe, re: Archaeological Testing planned for April 5-8, 2005, at HRA-26
▪ Notification to Gail Thompson, HRA, re: approval of blanket permit for burial, Archaeological Excavation Permit No. 04-03, with copies of notification letters to Roxanne Woodruff (Descendants of Fort Nisqually Employees Association), Larry Sanchez (Nisqually Indian Tribe), Dr. John Howard (Pierce County Chief Medical Examiner), Steve Young (Mayor, City of DuPont), Linda Naomi Goetz (President, AWA), and Bob Martin (Project Manager, DuPont Works Cleanup Project)
▪ Copy to Gail Thompson of letter from Descendants of Fort Nisqually Employees Association to Allyson Brooks, WA OAHP, re: HRA Application -- DuPont
▪ Notification to Allyson Brooks, WA OAHP, and Larry Sanchez, Nisqually Indian Tribe, re: archaeological testing planned for February 15-16, 2004, at 45PI713
▪ Copies to Gail Thompson of letters to Dr. John Howard (Pierce County Chief Medical Examiner), Judy Bridges (Descendants of the Employees of Fort Nisqually Association), Larry Sanchez (Nisqually Indian Tribe), Steve Young (Mayor, City of DuPont), Linda Naomi Goetz (AWA), and Bob Martin (Project Manager, DuPont Works Cleanup Project), re: HRA application for burial removal excavations within Parcel 1, former DuPont Works Site
▪ Copies of notification letters dated January 23, 2004, to Larry Sanchez (Nisqually Indian Tribe), Linda Naomi Goetz (AWA), Steve Young (Mayor, City of DuPont), and Bob Martin (Project Manager, DuPont Works Cleanup Project, re: approval of blanket permit for burial, Archaeological Excavation Permit No. 03-22
▪ Notification to Gail Thompson, HRA, re: approval of blanket permit for burial, Archaeological Excavation Permit No. 03-22
▪ Copies to Gail Thompson of letters to Larry Sanchez (Nisqually Indian Tribe), Steve Young (Mayor, City of DuPont), Linda Naomi Goetz (AWA), and Bob Martin (Project Manager, DuPont Works Cleanup Project), re: HRA application to conduct test excavations
▪ WA OAHP to G. Wessen, re: assignment of Smithsonian trinomials to three sites
▪ Request to Bill Tobin, Attorney, Nisqually Indian Tribe, re: Joe Kalama's participation in an Archaeology Month Event about the former DuPont Works site
▪ Copy to Gail Thompson of letter to Dr. Howard, Pierce County Medical Examiner, re: human remains from DuPont
▪ Transmittal to Ed Duke, Chief Investigator, Pierce County Medical Examiner's Office, of March 14, 2003, letter from Robert Martin, Weyerhaeuser, to Bill Tobin (Attorney, Nisqually Indian Tribe) and Allyson Brooks (State Historic Preservation Officer, WA OAHP), re: transfer and storage of remains from the Former DuPont Works Site; and April 16, 2003, letter from Burke Museum to Robert Martin, Weyerhaeuser
▪ Notification to Gail Thompson, HRA, re: determination of eligibility 45PI563

APPENDIX A.2 (AVAILABLE ON DVD)

FORMER DUPONT WORKS SITE ARCHAEOLOGICAL CORRESPONDENCE

CORRESPONDENCE.PDF

Description of Contents of Correspondence.pdf
▪ Response to Robert Whitlam, WA OAHP, re: determination of eligibility for 45PI563 (HRA-1), request for additional information in letter dated September 19, 2002
▪ Notification to Gail Thompson, HRA, re: determination of eligibility for HRA-1
▪ WA OAHP to Alex Maas, HRA, re: assignment of Smithsonian trinomial 45PI563 for HRA-1
▪ Request to Rob Whitlam, WA OAHP, for determination of eligibility, HRA-1
▪ Comments to Gail Thompson, HRA, re: Draft Research Design for Boundary Determination at 45PI55
▪ Transmittal to Larry Sanchez, Nisqually Indian Tribe, re: work plan for 45PI55 boundary delineation
▪ Transmittal to Allyson Brooks, WA OAHP, re: work plan for 45PI55 boundary delineation
▪ Comments to Gail Thompson, HRA, re: Draft Research Design for Boundary Determination at 45PI485
▪ Comments to Gail Thompson, HRA, re: Draft Research Design for Boundary Determination at 45PI404
▪ Transmittal to Larry Sanchez, Nisqually Indian Tribe, re: work plan for 45PI404 boundary determination
▪ Transmittal to Allyson Brooks, WA OAHP, re: work plan for 45PI404 boundary determination
▪ Transmittal to Larry Sanchez, Nisqually Indian Tribe, re: work plan for 45PI485 boundary determination
▪ Transmittal to Allyson Brooks, WA OAHP, re: work plan for 45PI485 boundary determination
▪ Fax to Dr. R. Daugherty re: request for boundary information at 45PI404

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

SA6-71-35	1.5-2	10/15/99	Yes	SA6-71-35	7439-92-1	Lead	6.9		mg/kg

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Sample Results for CM-05 Remediation Unit
Former DuPont Works: Weyco Site

Site ID	Depth (ft)	Sample Date [1]	Still In Place [2]	Sample No.	Cas No.	Constituent	Result	Qualifier	Units
SA2-44-69	2.5-3	10/14/99	Yes	SA2-44-69	7439-92-1	Lead	0.9	U	mg/kg
T337	0-0.5	04/17/03	Yes	01-SS-[T337]-C1_04/17/03_0	7439-92-1	Lead	73.3		mg/kg

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

T352	1-1.5	07/31/03	Yes	02-SS-[T-352]-C2_AVG_07/31/03_1	7440-38-2	Arsenic	19.8		mg/kg

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Table B.13
Sample Results for GC-05 Remediation Unit
Former DuPont Works: Weyco Site

Site ID	Depth (ft)	Sample Date [1]	Still In Place [2]	Sample No.	Cas No.	Constituent	Result	Qualifier	Units
T286	0-0.5	04/15/03	Yes	01-SS-[T286]-C1_04/15/03_0	7439-92-1	Lead	62.0		mg/kg

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

Note:

1. Exact sample dates were not available for a few historical samples collected in the third quarter of 1993. These were assigned a sample date of 7/2/1993.
2. "Yes" identifies the constituent concentration that met the cleanup goal. This is the last quantified concentration of this constituent at this location. Additional excavation may have occurred at this location to remove another constituent that was present in a concentration higher than the cleanup goal. "No" identifies constituent concentrations that were were above the cleanup goals and were therefore removed in later rounds of excavation.

1 Introduction

This report describes the activities that were undertaken in order to excavate hot spot soils at the former DuPont Works Site. This program was done as an interim action as allowed under the July 1991 Consent Decree signed by the Weyerhaeuser Company (Weyerhaeuser), E.I. duPont de Nemours and Company (DuPont) and the Washington State Department of Ecology (Ecology). The program was initiated in September of 1999 and completed in July of 2000.

1.1 Background

Areas with high arsenic and lead concentrations (referred to throughout this report as "hot spots") were discovered in isolated locations during site characterization sampling events at the former DuPont Works Site[1]. The majority of the elevated arsenic locations were along the narrow gauge railroad (NGRR) track while the majority of the elevated lead concentrations were within the immediate vicinity of specific building foundations.

The overall plan for the former DuPont Works Site involves excavating affected soils and placing them in specific areas (i.e., Placement Areas) within the future Golf Course boundary. Remediation Levels (RLs) for arsenic (530 mg/kg) and lead (4,100 mg/kg) have been agreed upon for the Placement Areas[2,3]. Hot Spot soils that have arsenic or lead concentrations greater than these RLs cannot be placed in the Placement areas.

The planned uses for the area within the Parcel 1 Consent Decree Boundary north of Sequalitchew creek are industrial purposes or open space. Additional excavations were completed in the area zoned for industrial use in order to achieve compliance with the Model Toxics Control Act (MTCA) Method C Soil Cleanup Levels (CL) of 90 mg/kg for arsenic, 33 mg/kg for 2,4,6-trinitrotoluene, and 1,000 mg/kg for lead[2].

1.2 Objectives

The two objectives of the hot spot program were:

1. **Commercial, Golf Course, and Open Space Areas** - Remove hot spots in property south of Sequalitchew creek that exceed the Golf Course Placement Area RLs (i.e., 530 mg/kg for arsenic and 4,100 mg/kg for lead).

2. **Industrial Area** - Remove the hot spots and other affected soils in the Industrial Area north of Sequalitchew creek in order to achieve compliance with Industrial CLs (i.e., 90 mg/kg for arsenic, 33 for 2,4,6-Trinitrotoluene and 1,000 mg/kg for lead).

A summary of the field activities is presented in Appendix A. The hot spot soils were excavated and stockpiled for future treatment and disposal which will be done as an interim action during the first half of 2001. Soils removed from the Industrial Area where the concentrations were less than 530 mg/kg arsenic and 4,100 mg/kg lead were placed in Golf Course Placement Area number two. Soils containing 2,4,6-trinitrotoluene were stockpiled separately and will be disposed of off-site during the first half of 2001. These 2,4,6-trinitrotoluene soils were not placed in the Placement Areas.

[3] Letter from Mike Blum, Washington State Department of Ecology to Vern Moore, Weyerhaeuser Company and Izzy Zanikos, Dupont Specialty Chemicals, Regarding: Soil Arsenic Non-Residential Remediation Levels, June 25, 1999.

2 Commercial, Golf Course, and Open Space Areas

2.1 Commercial and Golf Course Areas – Historical Data

The historical hot spot samples in the Commercial and Golf Course Areas (i.e., the portion of the property south of Sequalitchew creek) are identified in Table 1. Figures 1, 2, and 3 present the extent of the excavations as well as the post-excavation arsenic confirmation sample locations. Figures 4, 5, and 6 present the extent of the excavations as well as the post-excavation lead confirmation sample locations The sampling results are presented in Appendix C-1.

Sample 26-B-503-S-1 is located in a future Placement Area and was not removed because it will be covered with more than 15 feet of fill. All of the excavation samples and lateral confirmation samples are below the Golf Course Placement Area RLs. These areas will be evaluated further in the Remedial Investigation (RI), Risk Assessment (RA), and Feasibility Study (FS).

Table 1 – Historical Hot Spot Samples in the Commercial, Golf Course, and Open Space Areas

Sample ID	Analyte	Historical Result	Initial Sample Depth (feet)	Final Sample Depth (feet)	Action
1234-TP-510-S-1	Lead	8,200	0	1	Excavated to 1 foot

Figure 6

2.2 Commercial and Golf Course Areas – Hot Spot Data

During the hot spot program there were additional locations that were identified where the concentrations of arsenic and/or lead exceeded the Golf Course Placement Area RLs. All of these locations were excavated with the exception of the samples identified in Table 2. Samples 5-VS-125 and 5-VS-126 were not excavated because they are located in a future placement area and will be covered with more than 15 feet of fill. A cross section that identifies the sample locations and the depth of fill in the future placement area is presented in Figure 7.

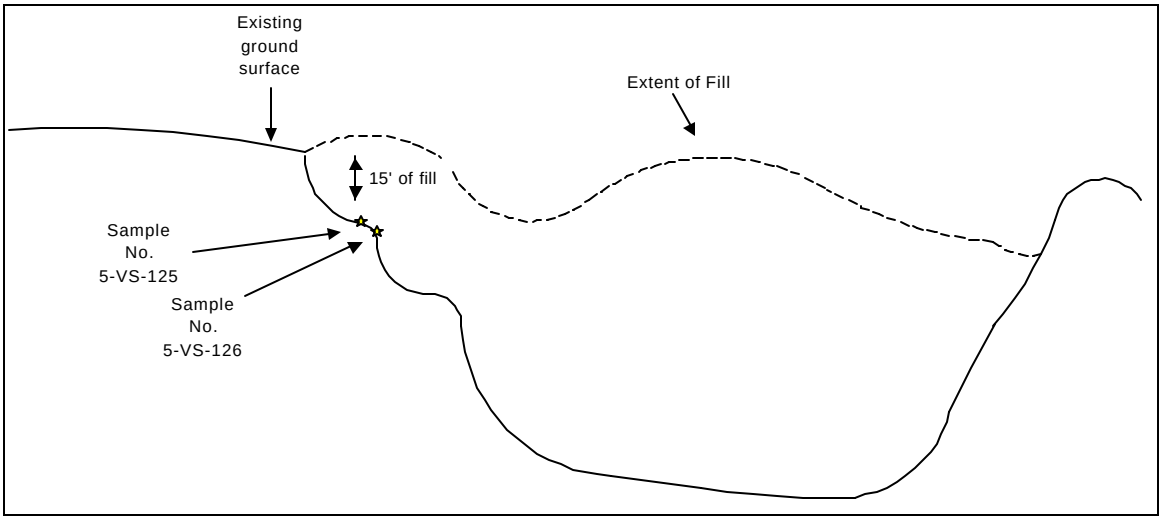
Table 2 – Hot Spot Samples Still in Place Greater Than 530 mg/kg for Arsenic

Sample Number	Analyte	Concentration (mg/kg)	Action
5-VS-125	Arsenic	1500	This sample is in a Placement Area and will be covered with more than 15 feet of fill.
5-VS-126	Arsenic	1500	This sample is in a Placement Area and will be covered with more than 15 feet of fill.
38-VS-56	Arsenic	970	This is a non-excavation confirmation sample result. In order to remove the sample the main haul road would have to be removed. This sample will be removed during site wide corrective action. This sample location will be addressed in the FS.

2.3 Open Space

No hot spot excavations were conducted in open space areas or in areas within or immediately adjacent to known historical sites. This included samples LR-311-25E, LR-68-B, LR-68-C, LR-68-S25, LR-68-S50, LR-68-S575, and LR-68-S75 which are located on or in the immediate vicinity of the NGRR within the Sequalitchew Creek Open Space Area. These and any other elevated sample locations within open space or historical areas will be addressed in the RI, RA and FS and will be remediated as part of the larger site-wide corrective action program.

Figure 7 – Cross Section With Existing Conditions, Sample Locations, and Elevation of Future Placement Area



3 Industrial Area

3.1 Hot Spots

The different historical hot spot samples that were present in the Industrial Area are identified in Table 3. Eight different excavation rounds resulted in the following 4 excavations in the Industrial Area:

- Burning Ground
- Narrow Gauge Railroad (NGRR)
- RR-546
- Area 10

The existing excavation in Area 10 was expanded to remove one 2,4,6-trinitrotoluene sample which exceeded the CL. The post-excavation confirmation sample locations and the associated excavation boundaries for each excavation are presented in Figure 8 for arsenic and 2,4,6-trinitrotoluene, Figure 9 for lead.

Table 3 – Historical Hot Spot Samples in the Industrial Area

Sample ID	Analyte	Historical Result	Initial Historical Sample Depth	Final Historical Sample Depth	Action
31-B-1,S-1	Lead	30,000	2.5	4	Excavated to 15 feet
31-B-501-S-1	Lead	25,000	0	3	Excavated to 2 feet (to gravel)
31-SS-2	Lead	240,000	0	0.5	Excavated to 2 feet (to gravel)

31-TP-13,S-1	Lead	17,000	0	3	Excavated to 2 feet (to gravel)
31-TP-15,S-1	Lead	6,500	0	3	Excavated to 2 feet (to gravel)
31-TP-16,S-1	Lead	25,000	0	3	Excavated to 2 feet (to gravel)
31-TP-8,S-1	Lead	6,300	0	3	Excavated to 2 feet (to gravel)
31-TP-9,S-1	Lead	28,000	0	3	Excavated to 2 feet (to gravel)
31-VS-13	Lead	29,000	0.5	1	Excavated to 2 feet (to gravel)
31-VS-14	Lead	56,000	0.5	1	Excavated to 2 feet (to gravel)
31-VS-16	Lead	75,000	0.5	1	Excavated to 2 feet (to gravel)
LR-104	Arsenic	690	0	0.5	Excavated to 2 feet
RR-546	Arsenic	950	0	0.5	Excavated to 1 to 2 feet
RR-546-A	Arsenic	640	0	0.5	Excavated to 1 foot
RR-595	Arsenic	570	0	0.5	Excavated to 1 to 2 feet

3.2 Evaluating Compliance With Cleanup Levels

The data for each of the four excavations and the remaining area were compared to the Industrial CLs of 90 mg/kg for arsenic, 33 mg/kg for 2,4,6-trinitrotoluene, and 1,000 mg/kg for lead. At Ecology's suggestion the following data were grouped in the following manner:

- Hot spot data outside each excavation (i.e., samples out to 25 feet from the perimeter of the excavation) were grouped together to demonstrate that the lateral extent of each of the excavations is in compliance with the CLs.
- Samples inside each excavation were grouped together to demonstrate that the vertical extent of each of the excavations are in compliance with CLs.

The compliance statistics are presented in Table 4. All four of the excavations, as well as the Industrial Area as a whole, are in compliance with the MTCA three-fold criteria.

Table 4 – Industrial Area MTCA Compliance Statistics

Analyte	Units	Num. Of Samps.	Num. Of Hits	Max Detect	Mean	95% UCL	Log Mean	95% Log UCL	Distribution type	MTCA UCL	Industrial Cleanup Levels	Number Greater than 2X the Cleanup Level	Percentage of samples greater than the Cleanup Level
All Data in Industrial Area (0 to 15 feet)													
Arsenic	mg/kg	405	380	180	21	23	10	25	Unknown	25	90	0	4.0%
Lead	mg/kg	445	398	2000	96	112	23	125	Unknown	125	1,000	0	1.1%

RR-546 Outside Excavation Samples													
Arsenic	mg/kg	8	8	89	58	70	56	75	Normal/Lognormal	75	90	0	0.0%
Lead	mg/kg	8	8	150	61	88	50	151	Normal/Lognormal	150	1,000	0	0.0%
NGRR Excavation Samples													
Arsenic	mg/kg	101	101	100	16	19	11	18	Lognormal	18	90	0	2.0%
Lead	mg/kg	101	99	390	22	30	11	24	Unknown	24	1,000	0	0.0%
Narrow Gauge Railroad Outside Excavation Samples													
Arsenic	mg/kg	56	55	110	34	40	23	49	Lognormal	49	90	0	7.1%
Lead	mg/kg	56	56	830	93	128	40	133	Lognormal	133	1,000	0	0.0%

Note: The following decision rules were followed for duplicate samples in order to develop a dataset for statistical analysis:

1. If all of the results were detected values, then the two values were averaged.
2. If all the results were non-detects then use the highest non-detected value.
3. If there was a mixture of detects and non-detects, then take the highest detected value.
4. The resulting value was assigned to the primary sample ID and the other duplicate samples were excluded from the data tables and figures.

4 Conclusions

Based upon the evaluation of the existing and collected data this program met its goals. No known contamination, greater than the chemical concentrations allowed for placement under the golf course, exists on the site other than:

- Two locations that will be buried greater than 15 feet deep during the golf course cap construction. (Ecology has determined that, for metals on the Site, direct contact with contaminated soils is the primary exposure route to humans. Fifteen feet is the depth of exposure, under MTCA, for direct contact.)
- One sample directly adjacent to the paved road that will be addressed in the FS.
- The samples in the Sequalitchew Creek Open Space Area. Addressing these sample locations was not part of this program. These samples locations will be addressed either within the FS or by a separate study.

In addition, the area north of Sequalitchew Creek, known as the Industrial Area, is in compliance with MTCA criteria for that land use. Pending Ecology's agreement, no further work will be done in this area during interim or site wide corrective action.

A greater than expected volume (an estimated 18,500 cubic yards) of soil was removed to meet program goals. The majority of this increased volume was removed from locations within the industrial area.

Appendix A – Summary of Sampling Activities

A.1 Project Management/Resources

This program was performed under the direction of the Site Management Team (ST). Jeff King of the West Shore Corporation, NW (WSNW), performed day-to-day oversight of the project activities. URS performed the confirmation sampling, and Sound Analytical Services, Inc. was the Project laboratory. Active Construction (ACTIVE) of Gig Harbor, Washington was the remediation contractor. PIONEER Technologies Corporation (PTC) managed the analytical data and developed the maps. The Hot Spot Interim Action Report was created collectively by WSNW, PTC, and URS.

A.2 Cultural and Archaeological Management

The program followed the criteria listed in the Projects' Cultural and Archaeological Management Plan. This plan, which is based upon cooperative agreements established between Weyerhaeuser, the Nisqually Tribe, and the Washington State Department of Archaeology and Historic Preservation (OAHP), identifies the terms for compliance for Site construction activities. As a result of this plan the following activities took place:

- All individuals involved in this program were trained by the Project's Archaeology Consultant, Western Heritage, on the identification of items of cultural or historic significance prior to the start of field work.
- Western Heritage was present on the site during the excavation and site preparation phases of the program.

A report describing the findings of, and any observations made, during this program will be issued to Ecology and OAHP within the next month.

A.3 Site Preparation

Phase One of this program included locating and flagging the hot spot locations and clearing and grubbing each work area. ESM Incorporated (ESM) of Federal Way, WA located and flagged the location of each hot spot. A field check of the locations was conducted and the boundaries of the work areas flagged by PTC and WSNW. Olympia Timber cleared and grubbed any trees and vegetation within 50 feet of each hot spot sample location and any other areas needed to safely complete the project. In addition, Olympia Timber removed all the remaining narrow gauge railroad tracks of Site, except those within Sequalitchew Creek canyon. Each area was then re-staked by ESM, to outline the initial excavation limit (to be set at 25 feet in the north, south, east and west directions from the original sample location). This resulted in a 50-foot by 50-foot initial excavation. In select cases where the impacted soils are greater than 1.5 feet deep, the initial excavation was 10 feet by 10 feet.

A.4 Field Construction Activities

The excavation of the hot spots was initiated after the site preparation activities were completed. In general the process consisted of two steps.

1. ACTIVE initially excavated to the perimeter of the staked area to depth of 1 foot except for the burning ground excavation and Area 19 excavations where, due to very high lead concentrations, the initial excavation depth was set at 2 feet. Once an area was excavated ACTIVE moved on to the next excavation. Decisions for further excavation were made once initial laboratory results were available.

2. When confirmation sampling detected *in situ* concentrations greater than CLs or RLs within or along the perimeter of the initial excavation further work was done. If the detection was outside of the excavation an additional 25 feet of soil was removed to the same depth as the excavation. If the detection was within the excavation the quadrangle containing the sample was excavated an additional one foot deeper. Confirmation samples were collected in the secondary excavation in the same manner as original excavation.

A.5 Sampling Confirmation Activities

A Hot Spot Removal Program Work Plan summarizing characterization procedures was prepared before field activities were initiated[4]. This Work Plan was generally consistent with the sampling and analytical activities specified in the 1992 Management Plan[5]. URS prepared a site-specific health and safety plan for use by on-site URS personnel.

Sampling begin once ACTIVE had completed 2 days of work. Samples were collected in accordance with the Work Plan. Soil samples were collected by placing soil into clean stainless steel bowls, mixing the soil with a clean stainless steel spoon to homogenize the sample, and then placing the soil into 4-ounce glass jars. The sampling equipment was decontaminated according to the work plan immediately prior to collecting each. Samples were held under chain-of-custody procedures at all times. The samples were delivered to the Project laboratory on a 3-day turn around basis.

Eight samples were collected for each 50-foot by 50-foot excavation. Excavation perimeter samples (four collected in the north, south, east and west directions from the sample location) were discreet samples. The four remaining samples in the bottom of the excavation were composites of five locations within each of the northwest, northeast, southwest and southeast quadrangles of the excavation. Sample results were issued to the Project Team upon receipt from the laboratory in a non-QA/QC basis. Decisions for further excavation were made based upon these results.

A.6 Secondary Excavations

Confirmation samples were done in the secondary excavation in the same manner as original excavation.

[5] HartCrowser. January 17, 1992. Management Plan. Remedial Investigation/Feasibility Study Former DuPont Works Site, DuPont, WA.

Appendix B – Laboratory Analytical Data Validation Results

B.1 Summary

The data reviewed are acceptable for use based on a majority of acceptable quality control data. The data meet criteria specified in the 1992 Hart Crowser Management Plan[6]. The data may be used to assess analyte concentrations with the stated qualifications.

B.2 Introduction

This section presents a quality control (QC) review of data generated from collection and analysis of soil samples from the former DuPont Works Site in Dupont, Washington, from September 10, 1999 through July 17, 2000. Samples were submitted to Sound Analytical Services, Inc. for analysis. This review includes evaluation of the following:

- Laboratory report and reporting of required analyses
- Chain of custody and holding times
- Method blanks
- Matrix spike / blank spikes (MS / BS)
- Laboratory duplicates
- Field duplicates
- Reporting limits

The data quality review was conducted using guidance from the following documents:

- National Functional Guidelines for Organic Data Review, EPA, February 1994.
- Remedial Investigation/Feasibility Study, Former Dupont Works Site Management Plan, Hart Crowser, January 1992.

Criteria used to assess the data are found in Section 5 of the Management Plan. The analytical data has been compared to the Management Plan limits. The samples were analyzed for the following chemicals, using the noted analytical methods.

Arsenic	EPA 6010
Lead	EPA 6010

B.3 Sample Case

The sample data groups identified in Table B-1 were included in this data review.

[6] HartCrowser. January 17, 1992. Management Plan. Remedial Investigation/Feasibility Study Former DuPont Works Site, DuPont, WA.

89910	30 May 2000
90806	29 June 2000
91163	18 July 2000
91278	24 July 2000

B.4 Laboratory Report and Reporting of Required Analyses

The laboratory report was complete; all QC results were included. The project scope of work stated that URS would provide industry-accepted evaluation of data quality and documentation of sample acquisition and custody. Comprehensive data validation was not requested for this sampling event. The reports provide all necessary information to complete this review. All analytical methods were reported as requested.

B.5 Chain of Custody and Holding Times

Samples were maintained under chain of custody until arrival at the laboratory. Samples were preserved and cooled until arrival at the laboratory. Sample bottles were in good condition. The samples were extracted and analyzed within the 6 month holding time. Holding times were within specifications of the Management Plan.

B.6 Method and Field Blanks

Method blanks were used to determine if samples were contaminated through laboratory procedures or equipment. The laboratory method blanks were free of target analytes (see Table B-2). The QC frequency requirement of one laboratory blank per analytical batch was met. Eight rinse blanks were analyzed. The field rinse blanks had detections of lead or arsenic. No data require qualification based on field rinse blank contamination.

Table B-2 – Method Blanks

Sample ID	Batch	Analyte	Result (mg/L)
Rinse Blank (rinsate)	84078	Lead	0.0032
Rinse Blank (rinsate 2)	84117	Lead	0.026
Rinse Blank (rinsate 3)	84117	Lead	0.016
Rinse Blank (rinsate 4)	84151	Lead	0.088
Rinse Blank (rinsate 5)	84215	Lead	0.031
Rinse Blank (rinsate 6)	84245	Arsenic Lead	0.034 0.026
Rinse Blank (rinsate 7)	84297	Lead	0.0061
Rinse Blank (rinsate 8)	84401	Lead	0.0065

B.7 Matrix Spikes/Blank Spikes

Matrix spike (MS) analyses were used to assess matrix effects with respect to the analytical data. The QC frequency requirement of one MS and one blank spike (BS) per analytical batch or one MS and one BS per 20 samples, was met.

The MS and BS results were compared to evaluate the accuracy of laboratory procedures. The spike recoveries ranged from 76 to 125 percent and were within the control limits with the following exceptions.

- Matrix spike 84055-1 (9-15/99): The lead percent recovery was above the control limits. The concentration of the spiked sample was at least 10 times greater than the spike added; therefore, no data were qualified.
- Matrix spike 84055-21 (9-15/99): The lead percent recovery was above the control limits. The concentration of the spiked sample was at least 10 times greater than the spike added; therefore, no data were qualified.
- Matrix spike 84078-42 (9/20/99): The lead matrix spike was not recovered. The concentration of the spiked sample was at least 10 times greater than the spike added; therefore, no data were qualified.
- Matrix spike 84117-1 (9/17/99): The lead matrix spike was not recovered. The concentration of the spiked sample was at least 10 times greater than the spike added; therefore, no data were qualified.
- Matrix spike 84117-21 (9/20/99): The lead matrix spike was not recovered. The concentration of the spiked sample was at least 10 times greater than the spike added; therefore, no data were qualified.
- Matrix spike 84151-1 (9/20/99): The arsenic percent recovery was below the control limits at 74%. The associated blank spike was within the control limits; therefore, no data were qualified.
- Matrix spike 84215-2 (9/22/99): The lead percent recovery was above the control limits. The concentration of the spiked sample was at least 10 times greater than the spike added; therefore, no data were qualified.
- Matrix spike 84215-22 (9/22/99): The lead percent recovery was below the control limits at 74%. The associated blank spike was within the control limits; therefore, no data were qualified.
- Matrix spike 84245-2 (9/21/99): The lead percent recovery was below the control limits at 64%. The associated blank spike was within the control limits; therefore, no data were qualified.

- Matrix spike 84245-40 (9/23/99): The percent recoveries were below the control limits for arsenic at 74% and lead at 72%. The associated blank spike percent recoveries were within the control limits; therefore, no data were qualified.
- Matrix spike 84297-22 (9/27/99): The percent recoveries were below the control limits for arsenic at 73% and lead at 72%. Associated quality control data were within the control limits; therefore, no data were qualified.
- Matrix spike 84297-42 (9/27/99): The percent recoveries were below the control limits for arsenic at 71% and lead at 69%. Associated quality control data were within the control limits; therefore, no data were qualified.
- Matrix spike 84320-1 (9/28/99): The percent recoveries were below the control limits for arsenic at 71% and lead at 66%. Associated quality control data were within the control limits; therefore, no data were qualified.
- Matrix spike 84320-21 (9/28/99): The percent recovery was above the control limit for lead at 133%. Associated quality control data were within the control limits; therefore, no data were qualified.
- Matrix spike 59069-21 (4/21/00): The arsenic and lead matrix spike percent recoveries were not recovered. The associated LCS and an additional matrix spike percent recoveries were within the control limits; therefore, no data were qualified.
- Blank spike S382 (9/20/99): The lead percent recovery was greater than the control limits at 133%. Associated data were qualified as estimated (J).
- Blank spike S392 (9/17/99): The lead percent recovery was greater than the control limits at 130%. Associated data were qualified as estimated (J).

B.8 Laboratory Duplicates

The relative percent differences (RPDs) ranged from 0 to 34 percent and were within the control limits established by the laboratory, with the following exceptions. No data were qualified due to laboratory duplicate RPDs.

- Laboratory duplicate 84030-15 (9/14/99): The lead RPD was above the control limit at 49% due to matrix interference. Associated quality control data were within the control limits; therefore, no data were qualified.
- Laboratory duplicate 84078-42 (9/20/99): The lead RPD was above the control limit at 58% due to matrix interference. Associated quality control data were within the control limits; therefore, no data were qualified.
- Laboratory duplicate 84508-21 (10/4/99): The arsenic RPD was above the control limit at 200%. The sample and duplicate results were not greater than five times the reporting limit; therefore, no data were qualified.
- Laboratory duplicate 85323-41 (11/5/99): The lead RPD was above the control limit at 46% due to matrix interference. Associated quality control data were within the control limits; therefore, no data were qualified.
- Laboratory duplicate 87040-41 (1/27/00): The arsenic RPD was above the control limit at 50% due to matrix interference. Associated quality control data were within the control limits; therefore, no data were qualified.

B.9 Field Duplicates

Field duplicate samples were used to assess sampling precision and representativeness. The QC frequency requirement of one field duplicate for 5 percent of the total samples, or one field duplicate per day at a minimum, specified in the Management Plan, was met. Forty-two sets of field duplicate samples were collected. Table B-3 presents the RPD of detected compounds that were calculated for the duplicate pairs. The RPDs were acceptable with the following exceptions:

- Duplicate pair 38-VS-96/117: the arsenic and lead results were qualified as estimated (J) due to the high duplicate RPDs.
- Duplicate pair 31-VS-586/587: the arsenic and lead results were qualified as estimated (J) due to the high duplicate RPDs.

- Duplicate pair 31-VS-639/686: the arsenic and lead results were qualified as estimated (J) due to the high duplicate RPDs.

Table B-3 – RPD of Detected Compounds

SAMPLE ID & DUPLICATE ID	ANALYTE	PRIMARY RESULT (µg/L)	DUPLICATE RESULT (µg/L)	RPD %

B.10 Reporting Limits

To ensure the level of analytical reporting sensitivity meets project goals, reporting limits were reviewed. Reported results are acceptable.

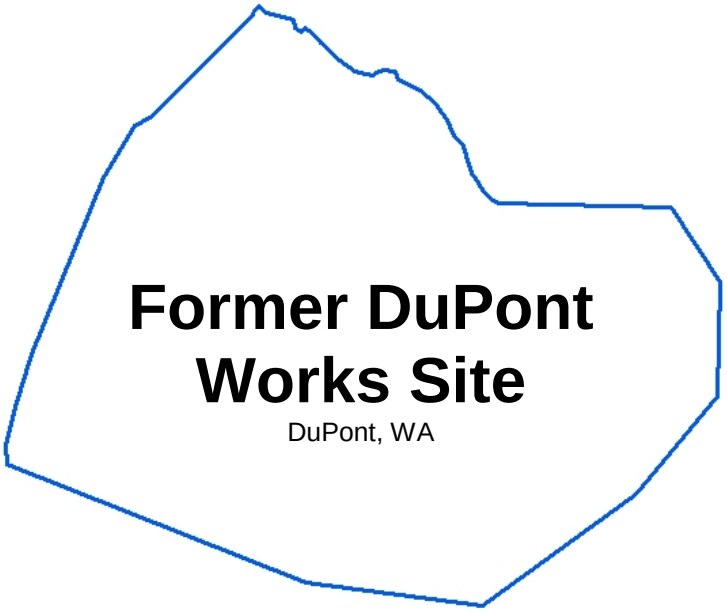
FINAL
Human Health and Ecological Risk Assessment for the Former DuPont Works Site



Prepared For:

The Weyerhaeuser Company **and** **E.I. duPont de Nemours and Company**

Prepared By:

July 2003

Preface

P.1 Introduction

These Volumes present information developed as part of the Final Remedial Investigation, Risk Assessment, and Feasibility Study (RI/RA/FS) for the Former DuPont Works Site (Site) located in DuPont, WA (See Figure P-1). These reports were stipulated in a Consent Decree, effective July 1991, between the lead agency, Washington State Department of Ecology (Ecology), and the principle responsible parties, Weyerhaeuser Company (Weyerhaeuser) and E.I. duPont de Nemours and Company, Inc. (DuPont). Per the Consent Decree, the reports were developed in accordance with the Model Toxics Control Act Cleanup Regulation (MTCA). Draft RI/RA/FS reports were completed in 1994 and 1995, submitted to Ecology, and underwent public review. The draft Final RI/RA/FS reports, presented here, have been developed to satisfy comments on the draft reports and to accurately reflect existing conditions and future land use at the Site. In addition, these reports incorporate a variety of agreements that have been reached with Ecology following completion of the draft studies in 1994 and 1995.

P.2 Property History

The Site property was originally used by Native Americans. European settlement began in 1832, when the Hudson's Bay Company established a cabin/storehouse on nearby Puget Sound at the mouth of Sequalitchew Creek, northwest of the Site (City of DuPont, 1995). In 1833, Hudson's Bay built Fort Nisqually, which was located in the northern portion of the Site. Ten years later, a new Fort Nisqually was built at a location adjacent to but outside the eastern edge of the Site.

The DuPont Company acquired the property in 1906 and constructed an explosives plant and the historical Village of DuPont as a company town for plant workers (the historical village area is located approximately 1 mile southeast of the Site). DuPont continued to manufacture explosives at the Site until the mid 1970s, when it sold the property and adjacent areas to the Weyerhaeuser Company. Weyerhaeuser and its subsidiary, Weyerhaeuser Real Estate Company (WRECO), still own the majority of the approximately 2,500 acres in the area, which they named Northwest Landing. Northwest Landing is a planned community in the City of DuPont and includes the Site. WRECO has begun to develop Northwest Landing on some of its lands within the City, but cannot develop the Site until the cleanup has been completed.

P.3 Site Regulatory History

The Site was used for the manufacture of commercial explosives from 1909 to 1976. Production of explosive material ceased and decommissioning of the buildings began in 1976, when Weyerhaeuser purchased the property from DuPont. As part of the cleanup process, asbestos was removed, salvageable materials were taken out, and structures were either burned or demolished. Actions taken at the Site subsequent to the shutdown in 1976 include the following:

- In 1985, Weyerhaeuser initiated studies to determine whether hazardous substances were present.
- In 1986, a Phase I Site Survey and Review was conducted to identify areas on Site that may be of environmental concern.
- In 1986, soil contamination was first documented and reported to Ecology.
- In 1987, a Phase II Site Characterization study was performed, which characterized the type, concentration, and distribution of constituents at 38 areas on the Site.

- In 1989, a Baseline Human Health Risk Assessment was performed using results of the Phase II survey.

- In 1991, Weyerhaeuser and DuPont signed a Consent Decree (No. 91 2 01703 1) with Ecology, where they agreed to study the Site and complete an RI, RA, and FS. The Site was divided into two main areas: Parcel 1 (approximately 636 acres); and Parcel 2 (approximately 205 acres).

- In 1994 and 1995, Draft RI, RA, and FS reports were submitted to Ecology and underwent public review.

- In 1996, based on the result of interim source removal actions, Ecology approved a Cleanup Action Plan (CAP) for Parcel 2 that provided for no further remediation activities except for the institutional controls to maintain the industrial use of Parcel 2.

- In 1997, Parcel 2 was deleted from the Consent Decree, and the deed requiring institutional controls to maintain the industrial use was recorded in the Pierce County Auditor's Office.

- Between 1990 and 2001, while studies and negotiations were ongoing, Weyerhaeuser and DuPont undertook numerous interim source removal actions to clean up soil and/or debris at the Site, in accordance with MTCA and the Consent Decree.

P.4 Description of Reports

In fulfillment of the provisions of the Consent Decree, RI, RA, and FS reports were prepared. A description of the contents of each of these reports is presented below.

- **RI** – The purpose of the RI was to collect sufficient information regarding the Site to enable the completion of the RA and FS. The RI characterizes the nature and extent of contamination based on the existing conditions at the Site. The RI Report presents the analytical data for the media that have been collected at the Site. The data are presented for each RI area, which was defined based on historical manufacturing and production operations at the Site.

- **RA** – In contrast to the RI, the RA evaluates Site conditions in relation to future land uses at the Site. The RA identifies default soil cleanup levels, and presents the methods used to derive Site-specific soil levels that are protective of human health and ecological receptors based on future land use. These cleanup levels and remediation levels are compared to Site constituent concentrations in order to identify which areas require additional evaluation in the FS.

- **FS** – The FS evaluates alternative potential cleanup methods designed to meet the remedial action objectives for the Site. The FS Report provides information for Weyerhaeuser and DuPont to recommend alternatives for remediation of selected areas, including both no action and action alternatives. Ecology will evaluate the FS and select the remedial measures it believes are appropriate. Weyerhaeuser and DuPont will complete the needed detailed design and implementation of the remedy selected by Ecology in the Cleanup Action Plan.

P.5 Report Organization and Documents

This RI/RA/FS report should be reviewed together to better understand the relationship between the Site study activities. The RI/RA/FS are interdependent Reports that are organized as follows:

Volume I – RI and Appendices
Appendix A - Field Procedures
Appendix B - Soil Quality Data
Appendix C - Groundwater, Surface Water and Freshwater Sediment Quality Data
Appendix D - Laboratory Physical Soils Testing

Appendix E - Data Quality Assessment

Volume II - RA and Appendices

Appendix A – Ecological Risk Assessment Summary
Appendix B – Evaluation Unit Sample Groupings
Appendix C – Letters and Other Documentation of Site-Specific Determinations
Appendix D – Toxicity Information For Select Constituents
Appendix E – Cleanup Level and Remediation Level Calculations
Appendix F – Summary Statistics and Comparison to Standards

Volume III - FS and Appendices

Appendix A – Description of Remediation Technologies for Soil
Appendix B – Overview of Soil Testing Procedures and Data Interpretation
Appendix C – Lead and Arsenic Soil characterization and Treatability Studies
Appendix D – Arsenic Wet Screening Study
Appendix E – Ranking of Alternatives
Appendix F – Cost Estimate for Remedial Alternatives Analyzed in Detail
Appendix G – Estimation of Minimum Soil Volume Required for Cost-Effective On-Site Treatment
Appendix H – Development of Soil Remediation Levels for the Golf Course Groundskeeper
Appendix I – Impracticability of Groundwater Remediation at the Former DuPont Works Site, DuPont, Washington.

An Executive Summary is included with each Volume.

Table of Acronyms and Abbreviations

Acronym/Abbreviation	Definition
BGS	Below Ground Surface
COPC	Constituent of Potential Concern
CPAHs	Carcinogenic Polycyclic Aromatic Hydrocarbons
CPF	Cancer Potency Factor
DNT	Dinitrotoluene
DuPont	E.I. duPont de Nemours and Company, Inc.
Ecology	Washington State Department of Ecology
EPA	U.S. Environmental Protection Agency
EU	Evaluation Unit
FS	Feasibility Study
IEUBK	Integrated Exposure Uptake Biokinetic Model for Lead
MSL	Mean Sea Level
MTCA	Model Toxics Control Act
NGRR	Narrow Gauge Railroad
PAHs	Polycyclic Aromatic Hydrocarbons
RA	Risk Assessment
RfD	Reference Dose for Noncarcinogenic Health Effects
RI	Remedial Investigation
RME	Reasonable Maximum Exposure
Subsurface	Greater than 1 foot to less than or equal to 15 feet below ground surface
Surface	0 to less than or equal to 1 foot below ground surface
TEF	Toxic Equivalency Factor
TNT	2,4,6-Trinitrotoluene
TPH	Total Petroleum Hydrocarbons
UCL	Upper Confidence Limit
WAC	Washington Administrative Code
Weyerhaeuser	Weyerhaeuser Company
WRECO	Weyerhaeuser Real Estate

Executive Summary

ES.1 Introduction

This Risk Assessment (RA) was conducted to evaluate the potential for adverse impacts to human health and the environment associated with the potential exposure to residual constituents present at the former DuPont Works Explosives manufacturing site (Site) located in Pierce County, Washington. Residual constituents are those constituents that remain in the soil, or other media, after the explosives manufacturing facility was decommissioned and after interim source removal of soil and debris. This Executive Summary summarizes the methods, inputs, and assumptions used to determine Site-specific cleanup and remediation levels, and identifies areas on the Site that are not in compliance with these standards, and that will therefore be addressed in the Feasibility Study (FS). The RA was conducted in accordance with a Consent Decree, effective July 1991, between the lead agency, the Washington State Department of Ecology (Ecology), and the principal responsible parties, Weyerhaeuser Corporation (Weyerhaeuser) and E.I duPont de Nemours and Company (DuPont).

The Site initially consisted of two parcels and is located within the limits of the City of DuPont, Pierce County, Washington (See Figure ES-1). Parcel 2 was remediated and is now used for industrial purposes. Parcel 1, which is the focus of this RA, is located in the western part of the City of DuPont.

ES.2 Background Information

Two risk assessment reports for the Site were written prior to this RA. In 1989, a preliminary draft RA was completed, and a second RA was completed in 1994. The 1994 draft RA underwent review cycles with Ecology and others, but was never finalized.

The RA presented here incorporates comments received on the 1994 Draft RA, and agreements and actions completed at the Site subsequent to that report. This RA was prepared in accordance with the Model Toxics Control Act (MTCA) Cleanup Regulation, Chapter 173-430 WAC. Using MTCA guidance, risk-based cleanup and remediation levels were developed for each constituent considering future land use, exposed populations, exposure pathways, and toxicity information, using prescribed noncancer and cancer risk goals. This was accomplished through completion of the following three tasks:

1. Data Evaluation, Reduction, and Screening.

2. Identification/Development of Cleanup Standards.

3. Comparison of Site Media Concentrations to Cleanup Standards.

The results of each of these tasks are presented in the following sections.

ES.3 Data Evaluation, Reduction, and Screening

Future land uses of the Site, evaluation units (EUs), media of concern, and a preliminary list of constituents of potential concern (COPCs), were identified in this task.

ES.3.1 Future Land Use

Based on a restrictive covenant, and in accordance with the Final Environmental Impact Statement, future use of the Site will include commercial, golf course, historical, industrial, and open space use. Commercial use will include development of offices and retail businesses, and will comprise approximately 636 acres of the Site. Most of the soil in commercial areas will be covered by buildings, parking lots, and roads. The remaining soil will be either professionally landscaped or covered with sidewalks. A golf course will cover approximately 187 acres of the Site. Historical areas on the Site include the 1833 Hudson's Bay Fort, the Shell Midden Site, the 404 Burial Site, and the Methodist Mission site (specific location is unkown). In total, the 1833 Fort, the Shell Midden, and the 404 site historical areas comprise approximately 6 acres of the Site. Industrial use may include activities ranging from

mining gravel to development of light industrial facilities. The area proposed for industrial use is north of Sequalitchew Creek and comprises approximately 36 acres of the Site. Open space use, which will occur in four areas of the Site, will encompass a total area of approximately 73 acres. The location of each of these future use areas is presented in Figure ES-2.

ES.3.2 Identification of Evaluation Units

The next step in the RA was identification of EUs. The EUs were developed based on the future Site uses described above, and were approved by Ecology. Future land use areas, such as the historical and open space areas, that were relatively small in size were evaluated without further division. The industrial land use area was also not divided. The commercial and golf course land use areas were divided into smaller EUs such that the smaller EUs were similar in size, consisted of contiguous property, and accounted for potential remedial alternatives. The RA EUs are presented in Figure ES-2.

ES.3.3 Media of Concern

Potentially affected media at the Site include surface soil (0-1 foot below ground surface [BGS]), subsurface soil (1 foot to 15 BGS), subsurface soil greater than 15 feet BGS, surface water (Old Fort Lake and Sequalitchew Creek), sediment (Old Fort Lake and Sequalitchew Creek), and groundwater. Based on the historical RI, preliminary and draft RAs, and ecological evaluations, it was determined that levels of COPCs in surface water and sediment were not of concern for protection of human and ecological receptors. Therefore, Ecology determined that no further action was warranted for these media (for more details see the current RI Report). In groundwater, DNT levels were slightly elevated above applicable groundwater standards.

ES.3.4 Preliminary Screening of COPCs

In the final step of this task, a preliminary list of COPCs was identified for further evaluation in the RA. This screening was conducted on a Site-wide basis (i.e., EUs were not screened individually in this step). In the initial screening step, sample results for all constituents were reviewed, and those constituents that were not detected in any samples were eliminated from further consideration. Following this screening step there were 38 detected constituents in surface soil and 52 detected constituents in subsurface soil >1 foot and $\leq$ 15 feet BGS, and 35 detected constituents in subsurface soil > 15 feet BGS.

In the last screening step, the maximum detected concentration for each constituent was compared to the most conservative (i.e., the lowest) soil cleanup levels and screening concentrations found in MTCA for the protection of groundwater, human health and ecological receptors. Following this screening step, there were 18 COPCs identified for surface soil and 19 COPCs identified for subsurface soil, and 3 COPCs identified for subsurface soil greater than 15 feet BGS. Constituents that did not have available risk-based screening concentrations were retained for further evaluation in the risk assessment. Soil samples analyzed for oil and grease were excluded from the RA due to the non-specificity of the analysis method, which measures both natural oils and greases and petroleum constituents.

ES.4 Identification of Soil Cleanup Levels and Remediation Levels

In this task, soil cleanup levels and remediation levels that are used to characterize potential impacts to human health and the environment, were identified. In addition, an area-specific background arsenic level was derived because the area background concentration is higher than MTCA soil cleanup levels. As previously mentioned, Ecology has determined that, with the exception of groundwater and soil, all media within the Consent Decree Boundary require “No Further Action”. Therefore, the cleanup levels and remediation levels identified were specific to soil. The presence of low levels of DNT in groundwater is addressed in the FS.

ES.4.1 Soil Cleanup Levels

Cleanup levels for soil are published in tables by Ecology, and are default values that can be used at any site. The only area on Site where these default cleanup levels apply is the industrial area located north of Sequalitchew Creek. These levels assume adult workers would be exposed to hazardous constituents through incidental soil ingestion, and were calculated using the algorithm and default exposure

assumptions identified in WAC 173-340-745. The other cleanup level used was 2,000 mg/kg for total petroleum hydrocarbons (TPH/diesel or heavier oils), which was taken from the MTCA Method A Table, in WAC 173-340-900. In addition, Site-specific cleanup levels for mercury, TPH (bunker C), total 2,4-dinitrotoluene and 2,6-dinitrotoluene (DNT), and 2,4,6-trinitrotoluene (TNT) were approved for use at the Site by Ecology (See Appendix C).

ES.4.2 Soil Remediation Levels

Soil remediation levels are site-specific levels based on protection of human health that are developed using exposure assumptions and other media-specific factors that reflect future site conditions. Remediation levels are calculated using human health risk assessment procedures and site-specific information, as specified in WAC 173-340-708. In order to apply remediation levels to site cleanup decisions, institutional controls (such as deed restrictions) are placed on properties with residual contamination to ensure that the exposure conditions applied to the derivation of these levels are maintained at the site in the future. Remediation levels were calculated for all constituents detected in at least one soil sample, unless the constituent did not have available toxicity information and was not directly linked to historical site operations.

The equations used to calculate remediation levels for all constituents except lead were obtained from WAC 173-340-740. Soil remediation levels were calculated using these equations, considering the potential reasonable maximum exposure (RME) for humans under each proposed land use with the exception of industrial use (for industrial use, MTCA default industrial cleanup levels were used, as described above). For lead, EPA has chosen to evaluate the potential adverse health effects using a physiologically-based model. The model currently used by EPA for establishing lead remediation levels in non-residential areas is the Adult Lead Model (EPA, 1996b). Using this model, site-specific remediation levels were developed for golf course worker, commercial landscape worker, and industrial worker scenarios. A hybrid approach using both the Adult Lead Model and the child Integrated Exposure Uptake Biokinetic Model for Lead (IEUBK), was used to derive a remediation level for open space areas.

ES.4.3 Ecological Soil Screening Concentration for Lead

Ecology has performed an evaluation of the Site and determined that lead is the indicator constituent for potential terrestrial ecological impacts. As part of this evaluation, Ecology determined that based on Site-specific information the potential species groups of concern included ground-feeding birds and herbivorous small mammals. The screening level identified by Ecology is 118 mg/kg and is intended to be protective of wildlife, including birds and small mammals. Exceedance of this value does not necessarily indicate that cleanup must occur, but that various other options could be explored to demonstrate that lead does not pose a threat to ecological receptors at the Site.

ES.4.4 Determination of Arsenic Background Level in Soil

In addition to the cleanup levels and remediation levels, an area background soil concentration was calculated for arsenic. As part of the RI investigation, soil samples were collected outside of the Consent Decree boundary to define the "Site Area Background" level of arsenic. As stipulated in WAC 173-340-709, twenty soil samples were collected to statistically establish area background levels. Based on the results of these samples, the site area background concentration for arsenic is 32 mg/kg. This value represents the 90^{th} percentile value of the distribution of the background samples.

A summary of the cleanup levels and remediation levels used for each future use scenario is presented in Table ES-1.

ES.5 Comparison of Site Soil Concentrations to Cleanup Levels and Remediation Levels

In this last task of the RA, soil concentrations for each EU were compared to the cleanup levels and remediation levels identified above. Only those COPCs that were detected in at least one sample and that had maximum concentrations that exceeded conservative risk-based screening criteria were evaluated in this task of the risk assessment.

The steps involved in this comparison included calculating the MTCA 95% Upper Confidence Limit (UCL) of the mean concentration (i.e., a conservative estimate of the mean) for each EU, comparing this concentration and the maximum detected concentration in each EU to cleanup standards applicable to the future use of each EU, and identifying EUs with COPC concentrations that do not comply with MTCA's Three-Fold Criteria [WAC 173-340-740 (7)(c),(d), and (e)]. In addition to the Three-Fold Criteria, constituents in each EU were also compared to MTCA's risk-based criteria.

ES.5.1 Comparison of EU Soil Concentrations to Cleanup Levels and Remediation Levels

The soil concentrations in each EU were compared to the cleanup standards to determine if the concentrations of COPCs in each EU comply with MTCA Three-Fold Criteria. The MTCA Three-Fold Criteria are the following:

1. The maximum soil concentration must be less than or equal to 2 times the site-specific cleanup level or remediation level.
2. The MTCA 95% UCL on the mean must be less than the site-specific cleanup level or remediation level.
3. Less than 10% of individual soil concentrations shall exceed the site-specific cleanup level or remediation level.

If any of these criteria are not met, then the EU is not in compliance, and was designated for evaluation in the FS.

ES.5.2 Comparison of EU Constituent Concentrations to MTCA Risk-Based Criteria

MTCA identifies risk-based criteria for constituents as follows:

1. The human health risk level for individual constituents may not exceed a hazard quotient of 1 or a cancer risk of one-in-a-million (1E-06) for historical, open space, golf course, and commercial EUs. The human health risk level for individual constituents may not exceed a hazard quotient of 1 or a cancer risk of one-in-one-hundred thousand (1E-05) for the industrial EU.
2. The total risk level at the site, based on cumulative exposure to all constituents, may not exceed a hazard index of 1 or a cancer risk of 1 in 100,000 (1E-05).

If an EU exceeds these criteria the EU does not comply with MTCA, and is carried through to the FS.

ES.5.3 Identification of EUs With COPCs in Soil That Exceed MTCA Three-Fold Criteria and/or MTCA Risk-Based Criteria

Each EU was evaluated using the MTCA Three-Fold Criteria and Risk-Based Criteria. Based on the results of this evaluation, the EU was determined to be in compliance or not in compliance with MTCA. The results of this evaluation are summarized below organized by future land use category.

ES.5.4 Commercial Land Use EUs

All commercial EUs were out of compliance with the MTCA Three-Fold Criteria and the Risk-Based Criteria. Arsenic and lead were the COPCs that exceeded the criteria most frequently.

ES.5.5 Golf Course Use EUs

All golf course EUs were out of compliance with the MTCA Three-Fold Criteria and the Risk-Based Criteria. Arsenic and lead were the COPCs that exceeded the criteria most frequently.

ES.5.6 Historical Use EUs

All historical EUs were out of compliance with the MTCA Three-Fold Criteria and the Risk-Based Criteria. Arsenic and lead were the COPCs that exceeded the criteria most frequently.

ES.5.7 Industrial Use EUs

There is only one industrial EU, which was in compliance with both the MTCA Three-Fold Criteria and the Risk-Based Criteria. There are a few instances though, where the soil concentrations exceed the soil-to-groundwater screening criteria.

ES.5.8 Open Space Use EUs

All open space EUs were out of compliance with the MTCA Three-Fold Criteria and the Risk-Based Criteria. Arsenic and lead were the COPCs that exceeded the criteria most frequently

ES.5.9 Summary of Results

All EUs were screened against MTCA's Three-Fold Criteria and Risk-Based Criteria. Using these criteria, all EUs except the industrial EU did not comply, and will require evaluation in the FS. Most criteria exceedances were noted in the surface soil samples. Arsenic and lead were the constituents responsible for almost all criteria exceedances in the EUs.

Table ES-2 presents a summary of the compliance status of each EU. Figures ES-3 and ES-4 present the EUs that did not comply with MTCA Three-Fold criteria and Risk-Based Criteria.

Table ES-1 – Soil Cleanup Levels and Remediation Levels Used for Evaluating EUs

Constituent	Commercial and Golf Course EU Cleanup and Remediation Levels (mg/kg)	Historical and Open Space EU Cleanup and Remediation Levels (mg/kg)	Industrial EU Cleanup Levels (mg/kg)
Explosives			
Monomethylamine Nitrate	19,900[(1)]	6,680[(1)]	28,350
Nitroglycerine	6,580[(1)]	368[(1)]	4,080
2,4,6-Trinitrotoluene	1.75[(2)]	1.75[(2)]	1.75[(2)]
Petroleum Hydrocarbons			
TPH (418.1)	7,600[(2)]	7,600[(4)]	7,600[(2)]
Inorganics			
Aluminum	NC	825,000[(1)]	NC
Arsenic	60[(2)]	32[(2)]	90[(2)]
Copper	90,900[(1)]	30,500[(1)]	130,000
Lead	118[(3)]	118[(3)]	1,000[(5)]
Mercury	24[(2)]	24[(2)]	24[(2)]
PAHs			
Benzo(a)Anthracene	126[(1)]	7.1[(1)]	18
Benzo(a)Pyrene	12.6[(1)]	0.71[(1)]	18
Benzo(b)Fluoranthene	126[(1)]	7.1[(1)]	18
Benzo(k)Fluoranthene	1260[(1)]	71[(1)]	18
Chrysene	12,600[(1)]	710[(1)]	18
Dibenzo(a,h)Anthracene	12.6[(1)]	0.71[(1)]	18
Indeno(1,2,3-c,d)Pyrene	126[(1)]	7.1[(1)]	18
Pesticides/PCBs			
Aldrin	5[(1)]	0.3[(1)]	7.7

Notes:
NC = Not of Concern. Concentration calculated was equivalent to a 100 percent concentration. Therefore, this constituent is not of concern for this future land use.
Cleanup Levels are shaded and are either calculated using MTCA default parameters or measured site-specific information.
[(1)] Calculated using Site-specific parameters.
[(2)] Based on agreement with Ecology.
[(3)] Ecological screening concentration.
[(4)] Ecology agreement for TPH that originated as Bunker C fuel. One Area has TPH that did not originate from Bunker C fuel. Those TPH data were compared to the MTCA Table A value of 2,000 mg/kg for heavy oils.

[(5)] MTCA default value used for Parcel 2.

Figure ES-4

Chapter 1 – Introduction

1.1 Introduction

This Risk Assessment (RA) was conducted to evaluate the potential for adverse impacts on human health and the environment associated with potential exposure to residual constituents present at the former DuPont Works Explosives manufacturing site (Site) located in Pierce County, Washington. Residual constituents are those constituents that remain in the soil, or other media, after the explosives manufacturing facility was decommissioned and after interim source removal of soil and debris. This report presents the methods, inputs, and assumptions used to identify areas on the Site with the potential for adverse impacts on human health and the environment that will be evaluated further in the feasibility study (FS). The RA was conducted in accordance with a Consent Decree, effective July 1991, between the lead agency, Washington State Department of Ecology (Ecology) and the principal responsible parties—The Weyerhaeuser Company (Weyerhaeuser) and E.I. duPont de Nemours and Company, Inc. (DuPont).

1.2 Location and Setting

1.2.1 Location and Site Characteristics

The Site initially consisted of two parcels and is located within the limits of the City of DuPont, Pierce County, Washington (see Figure 1-1). Remediation of Parcel 2 has been completed and this parcel was released for development by Ecology in December of 1997. Parcel 1, which is the focus of this RA, is located in the western part of the City of DuPont. The Site is bordered by Weyerhaeuser property to the north and west and Weyerhaeuser Real Estate Company (WRECO) property on the east, and south. Burlington Northern railroad property is adjacent to the Weyerhaeuser open space to the west. Puget Sound is located to the west of the Burlington Northern Railroad property.

1.2.2 Physical Setting

The significant physical features of relief across the Site are numerous glacial kettles (depressions), the east-west trending valley of Sequalitchew Creek, a steep bluff that partially borders Burlington Northern Railroad property, and a small kettle lake in the southern portion of the Site called Old Fort Lake. Site elevations generally range from 200 to 225 feet above mean sea level (MSL), except within the kettles, where elevations are approximately 150 feet above MSL. The Site lies in the Puget Sound area of the wet coniferous forest region and is generally forested with intermittent clearings associated with the former production activities. This document reflects Site conditions as of March 2002. Weyerhaeuser, DuPont, and Ecology recognize that there have been changes to the Site since that point in time.

Site soils consist primarily of Steilacoom gravels. These gravels are comprised of stratified sands and gravels. Soil horizons on top of the Steilacoom gravels consist of gravelly, sandy loam with variable amounts of organic matter.

Two water-bearing zones, or aquifers, occur beneath the Site—the shallow Water Table Aquifer, and the deeper Sea Level Aquifer. Across most of the Site, the relatively impermeable Aquitard within the "Olympia Beds/Possession Drift/Whidbey Formation/Double Bluff Drift sequence (Aquitard)" restricts vertical flow of groundwater, and separates the Water Table Aquifer from the deeper Sea Level Aquifer (Borden and Troost, 2001). Groundwater in the Water Table Aquifer flows toward the west-northwest, with local discharge via springs to upper Sequalitchew Creek. The deeper Sea Level Aquifer flows toward Puget Sound.

Surface water resources on the Site include Sequalitchew Creek and Old Fort Lake. The creek is fed by overflows from Sequalitchew Lake located approximately 1.4 miles east of the Site. The depth of Old Fort

Lake is shallow, and fluctuates with groundwater levels. Similar to Sequalitchew Creek, surface runoff to the lake is limited by rapid soil infiltration of rain water.

1.3 Risk Assessment Report Background

1.3.1 Preliminary Baseline Risk Assessment

In 1989, a preliminary baseline RA was conducted for the Site (ETI and Hart Crowser, 1989). Based on conditions present at the time, the preliminary baseline RA suggested that the estimated non-carcinogenic hazards associated with potential exposure to lead, arsenic and 2,4,6-trinitrotoluene (TNT) in soil were above levels of concern. In addition, the preliminary baseline RA suggested that the estimated cancer risks associated with potential exposure to 2,4-dinitrotoluene and 2,6-dinitrotoluene (DNT) and carcinogenic polycyclic aromatic hydrocarbons (cPAHs) in soil were above levels of concern.

The preliminary RA also evaluated the potential for ecological impacts. The preliminary ecological RA indicated that aquatic organisms were not likely to be exposed to concentrations that could cause adverse impacts. A qualitative evaluation of the potential impacts on terrestrial wildlife indicated that potential impacts might be associated with exposure to constituents in hot spots which were present at the Site. These hot spots have subsequently been removed (PIONEER and West Shore, 2001).

1.3.2 Draft Risk Assessment Former DuPont Works Site, DuPont Washington

In 1994, a draft RA was conducted to evaluate potential exposures at each RI Area (i.e., former production areas and other areas of concern) to constituents detected above MTCA screening levels (DERS and Hart Crowser, 1994). Future land uses evaluated in the draft RA included residential, recreational (including open space and golf course), commercial, and industrial land use. The potential hazards and risks for each land use were evaluated, and the results of the draft human health RA indicated that several residential land use areas required further evaluation in the FS including: Areas 36, 38, 39, AP-C, AP-E, and the narrow gauge railroad (NGRR) based on exposure to arsenic, lead, and/or mercury in soil. The only future golf course or commercial land use areas that were identified in the draft RA as requiring further evaluation in the FS were Area 19 A and C, because of elevated concentrations of lead in soil (The location of these RI areas is shown in Chapter 2, Figure 2-3). No future industrial or open space land use areas required further evaluation based on the results of the draft RA.

A quantitative ecological RA was also conducted following the U.S. Environmental Protection Agency's (EPA) general framework. Historical and current surveys of the Site were used to determine indicator species including blacktail deer, red fox, red-tailed hawk, and Townsend vole. Potential risks to these indicator species were evaluated using available habitat and feeding habit information along with available toxicity data. The results of the draft ecological RA indicated no potential risk to large terrestrial mammals or avian species. Hazard quotients greater than one were calculated for voles in soil based on exposure to arsenic and/or mercury exposure in six areas of the Site (Areas 16, 26, 38, 39, AP-E, and Narrow Gauge Railroad (NGRR)).

1.3.3 Final Risk Assessment

The 1994 draft RA was reviewed by Ecology and others, and comments were provided. Since that time there have been a number of technical work group meetings, and meetings with Ecology, to evaluate and address various issues. The work, agreements, and changes in proposed land uses that resulted from these meetings include the following:

- Comments on the draft RA from Ecology and the Public.

- An agreement with Ecology on soil cleanup levels for total dinitrotoluene (2,4-dinitrotoluene and 2,6-dinitrotoluene) (Ecology, 1996), 2,4,6-trinitrotoluene (Ecology, 2001), mercury (Ecology, 1993), total petroleum hydrocarbons (TPH) and carcinogenic polycyclic aromatic hydrocarbons (cPAHs) (Hart Crowser, 1996).

- An agreement with Ecology on a toxicity value for monomethylamine nitrate (MMAN) (Ecology and PIONEER, 1997).

- An agreement with Ecology on soil lead remediation levels for four land use types including, golf course, commercial, industrial, and open space (Ecology, 1999).

- An agreement with Ecology on soil arsenic remediation levels for three different land use types including, golf course, commercial, and industrial (Ecology, 1999b).

- A site background soil level for arsenic (See the RI).

- An agreement on the configuration of future land use evaluation units.

- A determination by Ecology that lead is the indicator compound for potential terrestrial ecological impacts.

- Extensive work to evaluate potential ecological risks at the Site (see Appendix A). Because no Site-specific agreements were reached regarding a lead cleanup level for ecological receptors, the current assessment utilizes an ecological soil screening concentration for lead developed by Ecology.

- Significant quantities of contaminated soil and debris have been removed and disposed of off-Site as the result of 2000 Hot Spot Removals and 2001 Interim Corrective Actions (PIONEER et al., 2000).

- Additional Site characterization data have been collected, including data for areas not addressed by the preliminary or draft RAs.

- Future land use has changed from what was evaluated in previous RAs.

1.4 Overview of the Risk Assessment Process

Risk assessment is an established approach to evaluate the potential for impacts to human health and the environment associated with exposure to toxic constituents. Risk assessment is a management-decision tool, and does not provide absolute statements about health and environmental impacts, and typically focuses on constituents and exposure pathways directly related to a site. These assessments do not address risks from other sources of exposure (e.g., dietary exposures), or risks from other constituents that are not associated with the site under evaluation. Risk managers use the results of risk assessments to assist in determining if a site, or portion thereof, requires remediation.

1.5 Comparison of the MTCA Risk Assessment Process with the EPA Superfund Risk Assessment Process

The risk assessment process identified in MTCA differs from the traditional EPA Superfund risk assessment process presented in Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (EPA, 1989). Under Superfund, risk assessments are typically comprised of the following five tasks:

1. **Data Evaluation, Reduction, and Screening**. This task identifies potential constituents of concern from analytical data obtained from the field-sampling program. Constituents detected in at least one sample during the field investigation are identified and screened against risk-based screening concentrations to obtain a final list of constituents of potential concern (COPCs) to be evaluated in the risk assessment.

2. **Exposure Assessment**. This task identifies potentially exposed populations (e.g., children, adults, and potentially, plants and animals), exposure scenarios, exposure pathways, and exposure factors. The algorithms used to calculate intake also are presented in this section.

3. **Toxicity Assessment**. This task identifies toxicity values for the COPCs identified in task 1. Toxicity values include noncarcinogenic reference doses and carcinogenic slope factors for humans and noncancer toxicity information for plants and animals.

4. **Risk Characterization**. This task presents the human noncancer and incremental cancer risks, and the ecological hazard quotients associated with exposure to the COPCs that were calculated using the information described in tasks 1 - 3.

5. **Uncertainty Analysis**. This task identifies key uncertainties that should be considered when assessing the risks developed in task 4.

After the initial Data Evaluation, Reduction, and Screening step, which is the first component of any evaluation, the MTCA risk assessment process could be described as performing an EPA Superfund risk assessment in "reverse". That is, risk-based cleanup levels and remediation levels are developed for each constituent considering land-use, exposed populations, exposure pathways, and toxicity information based on prescribed noncancer and incremental cancer risk levels. Under MTCA, human health risk assessments are typically comprised of the following 3 tasks:

1. **Data Evaluation, Reduction, and Screening (Chapter 2)**. This task identifies potential constituents of concern from analytical data obtained from the field-sampling program. Constituents detected in at least one sample during the field investigation are identified for further evaluation in the risk assessment. This is similar to task 1 in the Superfund risk assessment process.

2. **Development of Cleanup Levels and Remediation Levels (Chapter 3)**. This task identifies concentrations for each constituent that are protective of human health and/or the environment. For noncarcinogenic constituents these concentrations are established at levels that would not cause illness in humans. For carcinogenic constituents these concentrations are established at levels that would not cause exceedances of the allowable level of excess cancer risk (as defined in MTCA) in humans. If applicable to a particular site, cleanup levels and remediation levels also are established for each constituent at levels that would be protective of terrestrial or aquatic receptors (e.g., plants and animals). For human health risk assessments, this task generally incorporates elements of task 2 – Exposure Assessment and task 3 – Toxicity Assessment of the Superfund risk assessment process. That is, cleanup levels and remediation levels are developed for specific land-uses, potentially exposed populations, and typically incorporate the most current toxicity information.

3. **Comparison of Site Media Concentrations to Cleanup Levels and Remediation Levels (Chapter 4)**. This task compares the site media concentrations, identified and summarized in task 1, with the cleanup levels and remediation levels identified in task 2. This task is similar to the risk characterization task of the Superfund risk assessment process; but, the results of EPA Superfund risk assessments and MTCA risk assessments are expressed differently. The results of an EPA Superfund risk assessment are expressed as noncancer health effects or incremental cancer risks. In contrast, the results of a MTCA Risk Assessment are expressed as exceedances of the cleanup levels and remediation levels.

Throughout this report, tables and figures are presented at the end of each chapter in which they are discussed. Chapters in this report are supplemented by Appendices, that provide supporting documentation of items discussed in the text.

Chapter 2 – Future Land Use, RA Evaluation Units and Identification of COPCs

2.1 Introduction

The purpose of this Chapter is to identify the future land uses for the Site, delineate evaluation units (EUs), identify media of concern, and to identify COPCs that will be evaluated further in the risk assessment.

2.2 Future Land Use

In October 1999, Weyerhaeuser Company and WRECO filed a Declaration of Restrictive Covenant that specifies allowable land uses for the Site. The Restrictive Covenant was filed with the Pierce County Auditor (document no. 9910290750) and states that none of the property shall be developed or used for residential uses, schools, daycare facilities, parks or other recreational uses – with the exception that the golf course and related amenities shall be allowed. These restrictions on land uses apply to the current landowners and all future landowners, unless determined otherwise in a legal venue and with Ecology's approval.

Future Site use, according to the Final Environmental Impact Statement (Ecology, 2000), will include commercial, golf course, historical, industrial and open space uses (See Figure 2-1). North of Sequalitchew Creek is planned for industrial use and open space. South of Sequalitchew Creek is planned for mixed use. Most of the Site will undergo changes during development, including grading, paving, placement of buildings, addition of topsoil, soil amendments, and landscaping. Future Site use plans, as reflected in this RA, enable an assessment of potential future risk.

2.2.1 Commercial

The majority of the Site property will be used for commercial purposes such as offices and retail businesses. The majority of the soil in this area will be covered by buildings, parking lots, and roads. Areas that are not covered by a building or parking lot will have sidewalks and professionally maintained, landscaped areas. These landscaped areas will be prepared for planting by adding imported topsoil, plants, and shrubs. A layer of mulch, or similar cover, will be added for aesthetic and practical purposes (e.g., weed control). Figure 2-1 identifies the commercial land use areas that comprise approximately 334 acres.

2.2.2 Golf Course

Ecology has agreed that a golf course facility is compatible with the planned future use of the Site (Ecology, 2000). A golf course serves as an effective means to isolate soil on the Site that is contaminated with lead or arsenic. The golf course layout was designed in order to maximize coverage of areas that have elevated soil arsenic and lead concentrations. The golf course, presented in Figure 2-1, covers approximately 187 acres.

2.2.3 Historical

Three historical areas have been identified on the Site, including the Fort Nisqually Cemetery (45Pl404), the Shell Midden (45Pl72), and the 1833 Fort Nisqually Site (45Pl155). The historical areas consist of approximately 6 acres. The Methodist Mission site is an additional historical site (45-PI-66) but, whereas the size and actual location of the site are unknown, a stone marker has been placed in its approximate location. The location of each of these areas is identified in Figure 2-1.

2.2.4 Industrial

The area north of Sequalitchew Creek will be used for industrial purposes. Industrial use may include activities ranging from mining gravel to development of light industrial facilities. This area occupies 36 acres and is identified in Figure 2-1.

2.2.5 Open Space

A number of areas on the Site will be used for open space. The open space area north of Sequalitchew Creek encompasses the creek and the former NGRR bed leading down to Puget Sound. The open space area south of Sequalitchew Creek borders the creek and extends to the northern most portion of the consent decree boundary. The area surrounding Old Fort Lake has also been designated as open space. The open space areas comprise approximately 73 acres, 22 acres of which is the lake itself. The location of each of these areas is identified in Figure 2-1.

2.3 Identification of Evaluation Units

The RI Report presents data by RI Areas. For the purposes of the RI, the Site was separated into different areas based on former production activities or other related activities that may have resulted in releases of COPCs to the environment. For the RA, the Site has been separated into different EUs based on future land use. Figure 2-3 presents both the RI areas and RAs for comparison. In addition, Appendix B of the RA presents the sample numbers for each EU and identifies their associated RI Areas.

The EUs were derived based on future land uses of the Site and were approved by Ecology. Future land use areas such as the historical and open space areas, that are relatively small in size, were evaluated without further division. The industrial land use area also was not divided. The commercial and golf course areas were subdivided into smaller EUs using the following decision rules:

- EUs should be similar in size.
- EUs should consist of contiguous property.
- EU boundaries should take into account potential remedial alternatives. For example, the commercial area on the bluff overlooking Puget Sound would require a different remedial approach than the rest of the Site due to the topography. Therefore, this area was designated, as its own EU. Other small EUs include the 65-foot commercial buffers, which are on the southern, southeastern, and eastern borders of the Site. These areas may be left in their current state as a buffer, depending on the results of the RA.
- EUs for the Golf Course should be divided between groups of golf holes.

The RA EUs are presented in Figure 2-3 and the number of acres for each EU is summarized in Table 2-1.

2.4 Potentially Affected Media

Potentially affected media at the Site include surface soil (0-1 foot below ground surface [BGS]), subsurface soil (1 foot to 15 BGS), subsurface soil (greater than 15 feet BGS), surface water (Old Fort Lake and Sequalitchew Creek), sediment (Old Fort Lake and Sequalitchew Creek), and groundwater. Based on the historical RI, preliminary and draft RAs, and ecological evaluations, it was determined that levels of COPCs in surface water and sediment were not of concern for protection of human and ecological receptors. Therefore, Ecology determined that no further action was warranted for these media (for more details see the RI Report, Volume I). Soil and groundwater are discussed below. COPC concentrations in the RI indicated that, other than low DNT concentrations that were detected in 6 wells, groundwater is not a medium of concern. The presence of low levels of DNT in groundwater is addressed in the FS.

The RI identified elevated levels of COPCs in surface and subsurface soil. COPCs are identified for surface and subsurface soil based on frequency of detection and risk-based screening criteria in the following section.

2.5 Identification of COPCs

In an effort to focus the risk assessment on those constituents most likely to pose risk to human and ecological receptors, preliminary screening was performed. This screening was conducted on a Site-wide

basis (e.g., EUs were not screened individually in this step), and consisted of eliminating COPCs that were not detected in any samples, and eliminating COPCs that had maximum detected concentrations that were below conservative risk-based screening concentrations. These screening steps are discussed below.

Data quality has been assessed and is discussed in the RI (See Appendix E). The data review involved verification that chain-of-custody protocols were followed, verification that the laboratory followed its quality assurance program, and an independent evaluation by URS Inc. of any data quality exceptions noted by the laboratory. Although there were some data quality exceptions indicating that some concentrations are estimates, all of the data presented in the RI were deemed of sufficient quality to retain for use in the risk assessment.

2.5.1 Screening of Non-Detected COPCs

Sample results for all COPCs were reviewed, and those constituents that were not detected in any samples were eliminated from further consideration. A total of 38 detected constituents were detected in surface soil and 52 in subsurface soil. A summary of the COPCs detected in surface and subsurface soil is shown in Table 2-2.

2.5.2 Risk-Based Screening of COPCs

In this last screening step, the maximum detected concentrations of COPCs were compared to the most conservative (i.e., the lowest) soil screening concentrations found in MTCA. These screening criteria were based on the direct exposure to soil for both human and ecological receptors.

For protection of human health, based on direct contact exposure pathways with soil, the screening levels for all constituents except lead, gasoline, and total petroleum hydrocarbons (TPH 418.1) were MTCA Method B residential soil concentrations, obtained from Ecology's *Cleanup Levels and Risk Calculation (CLARC) Tables* (Ecology, 2001*).* These values were chosen because they were the most conservative values found for protection of human health. The screening concentrations for gasoline and TPH 418.1 were obtained from the MTCA Method A tables for soil because there are no corresponding MTCA Method B values. Soil greater than 15 feet BGS was not screened against these values as this depth of soil is not available for human contact.

Surface and subsurface soil COPC concentrations were also compared to MTCA soil screening concentrations that were derived to be protective of groundwater. Even though groundwater monitoring has shown DNT to be the only constituent of concern this screening was performed to identify any areas where leaching of COPCs from soil may potentially impact groundwater. The screening levels used were Ecology's MTCA Method B levels derived for the protection of groundwater, obtained from Ecology's *CLARC Tables* (Ecology, 2001*)*, and Site-specific levels designated for use by Ecology.

Ecology has performed an evaluation of the Site and determined that lead is the indicator compound for potential terrestrial ecological impacts. As part of this evaluation, Ecology determined that, based on site-specific information, the potential species groups of concern included ground-feeding birds and herbivorous small mammals. The soil screening level identified for lead by Ecology is 118 mg/kg, and is intended to be protective of wildlife, including birds and small mammals.

2.5.2.1 Screening Results for Soil-to-Groundwater

Results of this screening step for surface soil are shown in Table 2-3, results for subsurface soil (>1 foot to $\leq$15 feet bgs) are shown in Table 2-4, and results for deep subsurface soil (>15 feet bgs) are shown in Table 2-5. Based on this screening step, there were 5 COPCs that exceeded the soil-to-groundwater screening criteria in surface soil, 5 COPCs that exceeded the criteria in subsurface soil >1 foot to $\leq$15 feet BGS, and 3 COPCs that exceeded the criteria in subsurface soil > 15 feet BGS. A summary of the COPCs that exceeded soil-to-groundwater screening criteria is presented in Table 2-6. Groundwater remediation options for these COPCs are presented in the FS and groundwater was not evaluated further in the risk assessment as a medium of concern.

2.5.2.2 Screening Results for Soil

Results of this screening step for surface soil are shown in Table 2-3, and the results for subsurface soil (>1 foot to ≤15 feet BGS) are shown in Table 2-4. Following this screening step, there were 16 COPCs in surface soil that exceeded the screening criteria and 17 COPCs that exceeded the criteria in subsurface soil >1 foot to ≤15 feet BGS.

A summary of these COPCs identified in surface and subsurface soil is shown in Table 2-7. Those constituents that did not have available risk-based screening concentrations were included as COPCs to be carried through to the risk assessment. These constituents are also identified in Table 2-7. Soil samples analyzed for oil and grease (EPA Method 413.2) were excluded from the RA due to the non-specificity of the analysis method. This method measures natural oils and greases in addition to petroleum constituents.

Chapter 3 – Identification of Cleanup Levels and Remediation Levels

3.1 Introduction

This chapter identifies the cleanup levels and remediation levels that will be used in Chapter 4 to identify areas of the Site that will require further consideration in the FS. As stated in MTCA, preparation of the RI should involve identification of cleanup levels and remediation levels. Instead of including cleanup levels and remediation levels in the RI, they are presented here, so that their development can be explained in the context of protection of human and ecological receptors. For this Site, numerical criteria include cleanup levels, remediation levels, and an ecological screening concentration for lead.

As discussed in Chapter 2 of the RA, Ecology has determined that, with the exception of groundwater and soil, all media within the Consent Decree Boundary require "No Further Action" (See the RI) (URS, 2002). Groundwater was evaluated in Chapter 2, and carried from there to the FS where remediation options are considered. Therefore, the cleanup levels and remediation levels described below are specific to soil that is available for direct contact by human and ecological receptors.

3.2 Soil Cleanup Levels

Soil cleanup levels are published in tables (i.e., CLARC) by Ecology, and are default values that can be used at any site. Cleanup levels specified in MTCA are concentrations that are protective of humans for specific exposure scenarios (i.e., industrial land use and unrestricted future land use) (WAC 173-340-200). To supplement these MTCA table values, Ecology has approved Site-specific cleanup levels for a select group of constituents.

The only area on the Site where default cleanup levels are used is the industrial area located north of Sequalitchew Creek. These levels assume adult workers would be exposed to hazardous constituents through incidental soil ingestion, and were calculated using the algorithm and default exposure assumptions identified in WAC 173-340-745. These values are presented in Table 3-1. The other cleanup level used was 2,000 mg/kg for total petroleum hydrocarbons (TPH 418.1), which was obtained from the MTCA Method A Table, WAC 173-340-900.

Site-specific cleanup levels for mercury, total petroleum hydrocarbons (TPH), total dinitrotoluenes (DNT), and trinitrotoluene (TNT) are presented in Table 3-2. These Site-specific levels were approved for use at the DuPont Site by Ecology (See Appendix C).

3.3 Determination of Arsenic Background Level in Soil

In addition to the cleanup levels, an area background level was calculated for arsenic in soil because the cleanup level is below the background concentration. As part of the RI, soil samples were collected outside of the Consent Decree boundary to define the "Site Area Background" level of arsenic (See Chapter 2 of the RI). Area background samples are collected to determine the concentration of a constituent that is consistently present in the environment in the vicinity of a site, as a result of human activities unrelated to releases from the site.

As stipulated in MTCA regulations (WAC 173-340-709), twenty soil samples were collected to statistically establish area background levels. Based on the results of these samples, the site area background concentration for arsenic is 32 mg/kg. This value represents the 90^{th} percentile value of the distribution of the background samples. In accordance with MTCA (WAC 173-340-708), the cleanup level established for a constituent shall not be adjusted below the area background level.

3.4 Ecological Soil Screening Concentration for Lead

Ecology performed an evaluation of the Site and determined that lead is the indicator compound for potential terrestrial ecological impacts. As part of this evaluation, Ecology determined that based on site-

specific information, the potential species groups of concern included ground-feeding birds and herbivorous small mammals.

The soil screening level identified for lead by Ecology is 118 mg/kg. This value was obtained from the MTCA site-specific procedures for evaluating potential impacts to populations of terrestrial ecological receptors (WAC 173-340-7493). This value was derived by Ecology, using exposure models and chemical-specific input values for avian and mammalian species. Exceedance of this value does not necessarily indicate that cleanup must occur, but that various other options could be explored to demonstrate that lead does not pose a threat to ecological receptors at the site. Site-specific ecological studies and evaluations that have been performed are summarized in Appendix A.

3.5 Determination of Soil Remediation Levels

Soil remediation levels are site-specific levels based on protection of human health that are developed using exposure assumptions and other media-specific factors that reflect future site conditions. Remediation levels are calculated using human health risk assessment procedures and site-specific information, as specified in WAC 173-340-708. In order to apply remediation levels to site remediation decisions, institutional controls (such as deed restrictions) are placed on properties with residual contamination to ensure that the exposure conditions applied to the derivation of these levels are maintained at the site in the future. Remediation levels were calculated for all constituents detected in at least one soil sample, unless the constituent did not have available toxicity information and was not directly linked to historical site operations.

Remediation levels were calculated assuming exposure via incidental soil ingestion. The other most likely exposure pathway, inhalation of particulates, was not considered based on historical air monitoring conducted at the Site. As part of interim corrective actions on the Site, air monitoring was performed during times of soil excavation, where maximum soil disturbance was occurring in the most contaminated areas (i.e., hot spots) of the Site. Results from this air sampling indicated that airborne concentrations of arsenic and lead (the primary constituents of concern) were below analytical detection limits. The results from the most recent air monitoring activities are presented in *Interim Source Removal Actions: Air Monitoring Report* (PIONEER and West Shore, 2002). In addition, the majority of the Site will be developed and used for commercial purposes, industrial purposes, or for a golf course. The future development will result in very little property being available as a source for wind-blown particulate matter. Dermal contact with soil was not considered because the main constituents of concern at the Site (i.e., arsenic and lead) are not readily absorbed through the skin.

3.5.1 Scenarios for Future Site Use

According to the Final Environmental Impact Statement, future Site use will be commercial, golf course, historical, industrial, and open space (Ecology, 2000). As stated in Chapter 2, a restrictive covenant was filed for this Site stating that none of the property shall be developed or used for residential uses, schools, daycare facilities, parks, or other recreational purposes, aside from golf course use. The soil remediation levels presented below are based on these land uses. Each future Site use, including the potentially exposed populations is described briefly below. A more detailed description of the future land use at the Site is presented in Chapter 2.

3.5.1.1 Commercial Use

Some Site locations are anticipated to contain retail and commercial establishments, including municipal buildings. Most of the soil in these areas will be covered by buildings, parking lots, and roads. The receptor most likely to be exposed to soil in the commercial land use area is a professional adult landscaper who plants and maintains shrubs. The pathway of exposure considered for this worker is incidental soil ingestion.

3.5.1.2 Golf Course

Development of Site areas for a golf course will require addition of topsoil and turf to achieve the proper contouring. The finished golf course will have contouring soil plus turf separating golfers from residual constituents left in surface and subsurface soils. Under conditions of normal use, exposure to

constituents in soil will only occur for adult groundskeepers, who may be exposed while repairing irrigation lines, maintaining drainage ditches, or planting trees. The pathway of exposure considered for this worker is incidental soil ingestion. The FS evaluates a variety of different remedial alternatives including an engineered CAP/Cover. The RLs associated with an engineered cap/cover remedial alternative are discussed in Section 6.5.4 of the FS.

3.5.1.3 Historical Areas

Although access to historical areas on the Site will be limited to preserve any artifacts that remain, older children or adults occasionally may walk through these areas. Exposure to younger children (i.e., less than six years old) is considered unlikely due to access limitations. Exposure to these areas on the Site is assumed to be infrequent, and exposure to constituents in the soil in these areas is unlikely. However, to be conservative, it was assumed that an adolescent (age 7 to 18) could be exposed to constituents in soil in these areas in the same way they could be exposed in open space areas. As with open space areas, the pathway of exposure considered was incidental soil ingestion.

3.5.1.4 Industrial Use

Future industrial use may include activities ranging from mining gravel to development of light industrial facilities. Adult workers may have direct contact with soil containing residual levels of COPCs. As described in Section 3.2, Ecology has already developed soil cleanup levels based on default industrial exposure assumptions. These cleanup levels that were used for Parcel 2 of this Site will also be applied as cleanup levels in Parcel 1.

3.5.1.5 Open Space Areas

Part of the Site will be preserved as open space. Exposure to soil in these areas may occur to adolescents while playing there. Such exposure would be random, occurring primarily during the warmer, drier months. The pathway of exposure considered for the adolescents is incidental soil ingestion.

3.5.2 Remediation Level Equations

The equations used to calculate remediation levels were obtained from WAC 173-340-740. Soil remediation levels were calculated using these equations, considering the potential reasonable maximum exposure for humans under each proposed land use with the exception of industrial use (for industrial use, MTCA default industrial cleanup levels were used, as identified in Section 3.2).

3.5.2.1 Equation for Noncarcinogens

$$\text{Soil Remediation Level (mg/kg)} = \frac{RfD\ x\ ABW\ x UCF\ x HQ\ x AT_n}{SIR\ x AB1\ x EF\ x ED}$$

3.5.2.2 Equation for Carcinogens

$$\text{Soil Remediation Level (mg/kg)} = \frac{RISK\ x\ ABW\ x\ AT_c\ x UCF}{CPF\ x SIR\ x AB1\ x EF\ x ED}$$

Where:

RfD = Reference Dose (oral) for noncarcinogenic health effects (mg/kg-day).
ABW = Average Body Weight for the exposed person exposed (kg).
UCF = Unit Conversion Factor (mg/kg).
HQ = Target Hazard Quotient (unitless).
AT_n = Averaging Time for noncarcinogenic effects (days).
AT_c = Averaging Time for cancer effects (days).
SIR = Soil Ingestion Rate (mg/day).
AB1 = Gastrointestinal Absorption Fraction (unitless).
EF = Exposure Frequency (days/year).

ED = Exposure Duration (years).
RISK = Target Cancer Risk (unitless).
CPF = Carcinogenic Potency Factor $(mg/kg\text{-}day)^{-1}$.

3.5.2.3 Equation Input Values

The input values for these equations consist of exposure factors, which describe the exposure patterns of the receptors (i.e., exposure frequency, exposure duration, ingestion rate, gastrointestinal absorption fraction, body weight, and averaging time); toxicity values (i.e., reference doses and carcinogenic potency factors), and benchmark risks (i.e., target hazard quotients and target cancer risks). These input values are discussed below.

Exposure Factors

Exposure factors are used to estimate the intake level of a constituent. Using this estimated intake and incorporating the other input values, including toxicity values and benchmark risks (as defined in MTCA), soil constituent concentrations that are protective for each future Site use were calculated. Each of the exposure factors has a range of possible values associated with it. The exposure factor values chosen for each receptor (i.e., commercial, golf course, historical, industrial, and open space) were selected so that the combination of all exposure variables resulted in a reasonable maximum exposure (RME) for the given receptor. The six basic exposure factors are described below. All of these values were derived in collaboration with Ecology (Ecology, 1999a and 1999b).

- *Exposure Frequency* – The number of days per year that a person is exposed. For the commercial worker and golf course groundskeeper, exposure is assumed to occur 52 days/year (once per week); for the historical area and open space users, exposure is assumed to occur 104 days/year (2 days/week).

- *Exposure Duration* – The number of years over which exposure is assumed to occur. For the commercial landscaper and the golf course groundskeeper, the exposure duration was assumed to be 20 years, which is the MTCA default value for worker exposure duration. For the historical area and open space users, the exposure duration was assumed to be 12 years, which is the age range of the adolescent receptor.

- *Ingestion Rate* – The amount of soil ingested per day of exposure. For the commercial landscaper, golf course groundskeeper, historical area user, and open space user the soil ingestion rate was assumed to be 200 mg/day. This is a conservative (i.e., health protective) ingestion rate typically assumed for childhood exposure. For comparison, the MTCA default ingestion rate value typically used for adults is 50 mg/day.

- *Gastrointestinal Absorption Fraction* – This is the percentage of a constituent that is available for absorption by the gastrointestinal tract once ingested. This is typically a constituent-specific value, but based on direction given by Ecology this value was conservatively chosen to be 100% for all constituents.

- *Body Weight* – The average body weight, in kilograms, of the receptor being evaluated. For the commercial landscaper and golf course groundskeeper this value was assumed to be the MTCA default of 70 kg, the average weight of an adult (average of both females and males). For the recreational users (both historical and open space areas), this value was assumed to be 47 kg, the average weight of females and males between the ages of 7 and 18 (EPA, 1996a).

- *Averaging Time* – The number of days over which exposure is averaged. Exposure levels for carcinogens are averaged over the lifetime of the exposed individual (i.e., 75 years) while exposure levels for noncarcinogens are averaged over the duration of exposure. Therefore, for carcinogens, the averaging time is calculated as the exposure frequency (days/year) X 75 years lifetime expectancy. The averaging time for noncarcinogens is calculated as the exposure frequency (days/year) X exposure duration (years). The carcinogenic averaging time is calculated using 75 years as the exposure duration because it is assumed that exposure to a

carcinogen can cause cancer at any later time in your life. For noncarcinogens, it is assumed that the effect of exposure will be seen during the period of exposure.

A summary of the exposure factors used to calculate remediation levels is presented in Table 3-3.

3.5.2.4 Toxicity Values

The toxicity values used in this assessment include noncarcinogenic reference doses (RfDs) and carcinogenic potency factors (CPFs). Both carcinogenic and noncarcinogenic health effects must be considered when evaluating potential human health impacts. The potential for producing carcinogenic effects is limited to certain constituents (i.e., carcinogens); conversely, adverse noncarcinogenic health effects can potentially result from exposure to any constituent. Therefore, in many cases a constituent may only have a noncancer toxicity value and no carcinogenic toxicity value.

RfDs and CPFs are derived through an evaluation of the relationship between the amount of a constituent (either administered, absorbed or believed to be effective) and changes in certain aspects of the biological system (usually toxic effects) in the exposed population (animals and/or humans) in response to that chemical. EPA has evaluated numerous chemicals and has published the corresponding toxicity values, which have undergone peer review. The following sources of toxicity information were consulted to identify toxicity values for this assessment:

- The Integrated Risk Information System (IRIS) (EPA, 2001).
- The Health Effects Assessment Summary Tables–Annual Update (HEAST) (EPA, 1997).
- Ecology's Cleanup Levels and Risk Calculation (CLARC) Table Updates (Ecology, 2001b).
- EPA Region IX Preliminary Remediation Goal (PRG) Tables (EPA, 2000).

The values presented in IRIS have been "verified" by either the EPA Reference Dose/Reference Concentration (RfD/RfC) Work Group or the EPA Carcinogen Risk Assessment Verification Endeavor (CRAVE). These agency work groups conduct a verification process that leads to internal agency scientific consensus regarding risk assessment information for a chemical. All of the toxicity values presented in the HEAST document are considered "provisional" by EPA because an agency work group has not verified them. Provisional values are not listed in IRIS. EPA Region IX PRG Tables were consulted because they frequently contain provisional values published internally within EPA, by the National Center for Environmental Assessment (NCEA).

Since multiple toxicity values were available for some chemicals, the sources of toxicity information were prioritized as follows to select the toxicity values used in the risk assessment:

1. IRIS values
2. HEAST values
3. CLARC table values
4. PRG table values

The toxicity of any chemical depends on its route of entry into the body. In some cases a chemical may produce toxicity only at or near a specific route of entry and may not be toxic through other routes of exposure. Only oral toxicity values were used in the derivation of remediation levels because soil ingestion was the only exposure pathway considered. A description of RfDs and CPFs, including an explanation of how they are derived, is provided below.

<u>Reference Doses Definition</u>

The term RfD was developed by EPA to refer to a daily intake of a constituent to which an individual, including sensitive subpopulations, can be exposed without any expectation of adverse noncarcinogenic health effects (e.g., organ damage, biochemical alterations, birth defects). EPA has developed RfDs for

subchronic (i.e., short-term exposures) and chronic exposures (multiple exposures occurring over an extended period of time). An RfD is defined as "an estimate (with uncertainty spanning perhaps an order of magnitude or greater) of a daily exposure level for the human population, including sensitive subgroups, that is likely to be without an appreciable risk of deleterious effects during a portion of the lifetime (EPA, 1989)." RfDs are expressed in units of mg/kg-day.

RfD Derivation

Noncarcinogenic constituents are thought to exhibit threshold characteristics. That is, exposures less than a specific threshold dose will not result in adverse health effects, whereas exposures exceeding the threshold dose may produce adverse health effects. The assumption of a threshold for toxicity is based on the concept that the body has certain protective mechanisms that must be overcome before adverse effects are manifest. For example, there could be a large number of cells performing the same or similar function whose population must be significantly depleted before the effect is seen.

The threshold concept is important in the regulatory context. The individual threshold hypothesis holds that a range of exposures from zero to some finite value can be tolerated by the organism without expression of the toxic effect. Further, it is often prudent to focus on the most sensitive members of the population; therefore, regulatory efforts are generally made to keep exposures below the population threshold, which is defined as the lowest of the thresholds of the individuals within a population (EPA, 2001).

In general, an RfD is derived from a no-observed-adverse-effects-level (NOAEL) or a lowest-observed-adverse-effects-level (LOAEL) obtained from animal studies (however, occasionally they may be derived from human studies) by the application of standard order-of-magnitude uncertainty factors. In certain cases, an additional modifying factor is employed to account for professional assessment of scientific uncertainties in the available data (EPA, 1989).

A NOAEL is an experimentally determined dose at which there was no statistically or biologically significant indication of the toxic effect of concern. The study chosen to establish the NOAEL is based on the criterion that the measured endpoint represents the most sensitive target organ or tissue (i.e., critical organ) for that chemical. In an experiment with several NOAELs, generally the lowest one is chosen as the critical NOAEL. Since many constituents can produce toxic effects on several organ systems, with each toxic effect possibly having a separate threshold dose, the distinction of the critical toxic effect provides added confidence that the NOAEL is protective of human health.

Once the critical NOAEL is identified, the next step is to derive the RfD by dividing the NOAEL by safety factors, as follows:

$$RfD\ (average\ daily\ human\ dose) = \frac{NOAEL_{Experimental\ Dose}}{Safety\ Factors + Modifying\ Factor}$$

Generally, each safety factor represents a specific area of uncertainty inherent in the available data and accounts for uncertainties, such as:

- Differences in responsiveness between humans and animals in prolonged exposure studies (factor of 10) (EPA, 2001).
- Variation in susceptibility among individuals in the human population (factor of 10) (EPA, 2001).
- Incomplete databases (e.g., those for which only the results of subchronic studies are available) (factor of 10) (EPA, 2001).

In addition to the safety factors, EPA applies a modifying factor in some instances. Modifying factors range from 0 to 10 and are included to reflect a qualitative professional assessment of additional uncertainties in the critical study and in the entire database for the chemical not explicitly addressed by the uncertainty factors. The default value for the modifying factor is 1 (EPA, 1997).

Cancer Potency Factors Definition

A cancer potency factor (CPF) is a numerical estimate of the carcinogenic potency of a constituent. CPFs are expressed in units of the inverse of milligrams of constituent per kilogram of body weight per day (kg-day/mg). CPFs were used in this assessment to calculate remediation levels that would result in carcinogenic risks within acceptable benchmark levels (see explanation of benchmark levels presented below).

CPF Derivation

The mechanism for carcinogenesis is considered to be a "non-threshold" process, since any level of exposure to such a constituent is considered to pose a small, but finite, probability of generating a carcinogenic response. Since risk at low exposure levels cannot be measured directly either by animal experiments or by epidemiologic studies, a number of mathematical models and procedures have been developed for use in extrapolating from high to low doses. Different extrapolation models or procedures, while they may reasonably fit the observed data, may lead to large differences in the projected risk at low doses. EPA assumes in developing CPFs that a single interaction with DNA can initiate cancer, so that low-dose extrapolation can be performed to nearly zero exposure. Making zero a data point affects the slope of the extrapolation curve and, therefore affects the CPF. This means that the relatively high doses that are often used in animal studies can be extrapolated downward to extremely small doses, with some incremental risk of cancer always possible. This assumes that even a small number of molecules (possibly a single molecule) of a carcinogen may cause changes in a single cell that could result in the cell dividing in an uncontrolled manner, eventually leading to cancer.

There is some dispute as to whether linear extrapolation to zero is a valid approach since cells have a number of detoxification mechanisms, such as DNA repair enzymes, that can repair damage from carcinogens at low doses. This would result in a threshold below which damage from carcinogens could be rectified. The presence of a threshold would result in a different slope for the extrapolated dose-response curve, and would result in a different CPF.

CPFs are usually derived by EPA using a linearized multistage model and reflect the upper-bound limit of cancer potency of any constituent. As a result, the calculated carcinogenic risk is likely to represent a plausible upper limit to the risk. The actual risk is unknown, but is likely to be lower than the predicted risk, and may be as low as zero (EPA, 1989).

Previously, EPA used a weight-of-evidence approach to classify the likelihood that a constituent is a carcinogen. Each chemical was placed in one of the weight-of-evidence groups presented in Table 3-4. New EPA guidance recommends using a different weight-of-evidence approach for characterizing carcinogens. EPA though, has not made any changes to IRIS reflecting the new weight-of-evidence guidelines.

Toxic Equivalency Factors Used to Derive CPFs

Toxic equivalency factors (TEFs) were used to derive CPFs for the carcinogenic polycyclic aromatic hydrocarbons (PAHs) evaluated in this assessment. TEFs are estimates of the toxicity of carcinogenic PAHs relative to the toxicity of benzo(a)pyrene, which is assigned a TEF of 1.0. The CPF for a carcinogenic PAH was derived by multiplying the CPF of benzo(a)pyrene by the TEF value for the carcinogenic PAH. The TEF values used in this assessment are presented in Table 3-5.

COPCs With No Available Toxicity Values

The COPCs with no available toxicity information were benzo(g,h,i)perylene, 2-methylnaphthalene, monomethylamine nitrate (MMAN), and phenanthrene. With the exception of MMAN, remediation levels were not calculated for these COPCs. Because MMAN is a constituent that was directly linked to explosives manufacturing at the Site, special effort was made to derive a toxicity value for use in this assessment. A description of the steps used to derive the toxicity value for MMAN is presented in Appendix D.

Toxicity Values Used to Calculate Remediation Levels

The toxicity values used to calculate remediation levels for each constituent are presented in Table 3-6.

Risk Benchmark Values

The last category of equation input values are the risk benchmark values that Ecology has used to define the "acceptable" risk level for a person exposed to COPCs. The benchmark values used are the target hazard quotient (HQ), which is the benchmark for noncarcinogenic effects, and the target cancer risk (RISK), which is the benchmark for carcinogenic risk. These are discussed below.

Target Hazard Quotient

The potential for adverse noncarcinogenic effects from exposure to a site-related constituent is quantitatively expressed as a hazard quotient (HQ). The HQ is the ratio of the estimated dose of a particular constituent to the reference dose (RfD) for that constituent:

$$HQ = Estimated\ Dose \div RfD$$

The RfD is the average daily intake of a constituent to which an individual, including members of sensitive subpopulations, can be exposed for a lifetime of 70 years without any expectation of adverse noncarcinogenic health effects (e.g., organ damage, biochemical alterations, birth defects). The average daily intake was calculated using the exposure factors described in this Chapter.

If the HQ for a constituent is less than 1.0, it indicates that adverse noncarcinogenic health effects are unlikely. If the hazard quotient is greater than 1.0, it indicates that adverse health effects are possible but the magnitude of these effects is uncertain. In other words, the hazard quotient does not represent a probability of occurrence or a quantification of the magnitude of noncarcinogenic health effects. In accordance with MTCA guidance (173-340-740 WAC and 173-340-745 WAC) the target HQ for individual constituents was set at 1.0 for all land use scenarios.

Target Cancer Risk

The risk of developing cancer from exposure to a constituent is described in terms of the probability that an exposed individual will develop cancer during a lifetime from that exposure. The risk estimate is calculated by multiplying the estimated dose of a particular constituent over a lifetime by the carcinogenic potency factor.

$$RISK = Estimated\ Dose \times CPF$$

A 1 in 1,000,000 cancer risk (i.e., 1E-06) means that an individual could have an additional 1 in 1,000,000 chance of developing cancer over a 70-year lifetime due to exposure to the constituent. The target RISK for individual constituents was set at 1E-06 for open space and historical land uses (using the target risk for residential exposures set by MTCA in 173-340-740 WAC) and at 1E-05 for commercial and golf course land uses (using the target risk for industrial exposures set by MTCA in 173-340-745 WAC).

3.5.2.5 Site-Specific Remediation Levels

The Site-specific remediation levels calculated for future commercial, golf course, historical, and open space uses are presented in Table 3.7. Spreadsheets containing remediation level calculations are presented in Appendix E.

3.5.3 Approach for Derivation of Soil Lead Remediation Levels

EPA has chosen to evaluate the potential adverse health effects of lead using a physiologically-based model. Therefore, lead has not been assigned toxicity values (i.e., no RfD or CPF is available), which are required to calculate Site-specific remediation levels using the MTCA formulas described above. The model currently used by EPA for establishing lead remediation levels in non-residential areas is the Adult Lead Model (EPA, 1996b). This model utilizes a methodology to estimate a fetal blood lead concentration in women exposed to lead contaminated soils. A developing fetus is considered the most sensitive

receptor associated with adult exposure to lead. The adult lead model is the only currently available tool for the development of non-residential remediation levels that has undergone sufficient peer review and technical refinement to justify its use in Washington State (Ecology, 1998). Using this model, Site-specific remediation levels were developed for golf course worker, commercial worker, and industrial worker scenarios. A hybrid approach using both the Adult Lead Model and the child Integrated Exposure Uptake Biokinetic Model for Lead (IEUBK) (EPA, 1994) was used to derive a remediation level for open space areas. This approach is discussed separately below.

3.5.3.1 Derivation of Commercial, Golf Course, and Industrial Remediation Levels

The adult lead model used to derive commercial, golf course, and industrial remediation levels uses a simplified representation of lead biokinetics to predict quasi-steady state blood lead concentrations among adults (i.e., women of child-bearing age) who have relatively steady patterns of exposure to lead contaminated soil. Fetal blood lead concentrations are then predicted assuming that they are proportional to maternal blood lead concentrations. The acceptable lead concentration in soil is based on limiting the fetal blood lead level to 10 *u*g/dL. The equations used to calculate the risk-based remediation level (RBRL) are the following:

$$RBRL = PbS = \frac{\left(PbB_{adult,central,goal} - PbB_{adult,0}\right) \times AT}{\left(BKSF \times IR_s \times AF_s \times EF_s\right)}$$

and

$$PbB_{adult,central,goal} = \frac{PbB_{fetal,0.95,goal}}{GSD_{i,adult}^{1.645} \times R_{fetal/maternal}}$$

Where:

RBRL	=	Risk-based remediation level for lead (ug/g).
PbS	=	Soil lead concentration that would be expected to result in a protective fetal blood lead concentration (ug/g).
$PbB_{adult,central,goal}$	=	Goal for the central estimate of blood lead concentration (ug/dL) in women of child-bearing age that have site exposures. The goal is intended to ensure that $PbB_{fetal,\ 0.95,goal}$ does not exceed 10 ug/dL.
$PbB_{adult,0}$	=	Typical blood lead concentration (ug/dL) in a woman of child-bearing age who does not receive exposure to lead-contaminated soil at the site.
AT	=	Averaging time; the total period during which soil contact may occur (365 days/year).
BKSF	=	Biokinetic slope factor relating (quasi-steady state) increase in typical adult blood lead concentration to average daily lead uptake (ug/dL blood lead increase per ug/day lead uptake).
IR_S	=	Intake rate of soil, including both outdoor soil and indoor soil-derived dust (g/day).
AF_S	=	Absolute gastrointestinal absorption fraction for ingested lead in soil and lead in dust derived from soil (unitless).
EF_S	=	Exposure frequency for contact with assessed soils and/or dust derived in part from these soils during the averaging time (days/year).
$PbB_{fetal,0.95,goal}$	=	Goal for the 95th percentile blood lead concentration (ug/dL) among fetuses born to women having exposures to the site soil lead.
$GSD_{i,adult}$	=	Estimated value of the geometric standard deviation (unitless) for women of child-bearing age. This value addresses the difference in response (i.e., difference in intakes and biokinetics) among women exposed to similar on-site concentrations. The exponent, 1.645, is the value used to calculate the 95th percentile

$R_{fetal/maternal}$ = Proportionality constant between fetal blood lead concentration and maternal blood lead concentration (unitless).

More detailed information regarding the derivation of this equation and assumptions used in the model are presented in *Recommendations of the Technical Review Workgroup for Lead for an Interim Approach to Assessing Risks Associated with Adult Exposures to Lead in Soil* (EPA, 1996b). The equation input parameters used for each scenario are presented below in Table 3-8.

3.5.3.2 Derivation of Historical and Open Space Use Remediation Level

The historical and open space use remediation level for lead was derived by Ecology, using a hybrid approach that combined results from using the IEUBK with results obtained from using the Adult Lead Model (Ecology, 1999a). A hybrid approach was used for recreational use areas because exposure under this scenario is to a child of age between 7 and 18 years and neither model used is specific for this age group. There is no specific age at which an older child's biokinetics respond similarly to an adult (it is therefore hard to determine how applicable the adult model is), and most researchers agree that young children (0-6 years old- the age that the IEUBK was designed for) absorb lead more readily than an older child. The use of each lead model and the final derivation of the historical and open space use remediation level are described below.

Use of the IEUBK Model

The IEUBK model evaluates childhood residential exposures to lead. The model was developed considering children since they are more sensitive to the neurological effects of lead than adults. The IEUBK model integrates exposure from lead in air, water, soil, dust, diet, and paint with pharmacokinetic modeling to arrive at a "screening level" for lead in residential soils (EPA, 1994). Using Site-specific and standard default input parameters, a soil lead screening level of 450 ug/g was obtained (Ecology, 1997). At this soil concentration, the probability of exceeding a child's target blood lead concentration of 10 ug/dl should be no more than 5 percent.

Using the screening level of 450 mg/kg, an exposure ratioing approach was used to modify this number to reflect the exposure frequency expected for a child playing in the open space areas on the Site (the exposure frequency assumed in derivation of the screening level is 7 days/week, which is much higher than that assumed for a child playing in open space areas). Accordingly, if a child were assumed to play in the open space areas one day per week, the screening level would be modified as follows:

(7 days/week ÷ 1 day/week) * (450 mg/kg) = 3,150 mg/kg

Exposure frequencies of 2 and 3 days per week result in remediation levels of 1,575 and 1,050, respectively.

Use of the Adult Lead Model

The adult lead model is described in detail in Section 3.5.3.1. For use in calculating remediation levels for an older child, the maternal/fetal blood lead ratio was eliminated and the goal of protecting 95% of the older child population from exceeding 10 ug/dl blood lead was retained. The geometric standard deviation and baseline blood lead level input remained unchanged. Using the Adult Lead Model in this manner, and assuming exposure frequencies of 1, 2,and 3 days per week resulted in remediation levels of 3,512 mg/kg, 1,756 mg/kg, and 1,171 mg/kg, respectively.

Historical and Open Space Use Remediation Level

Use of the two different models yielded remediation levels of approximately 1,050 to 3,150 mg/kg (IEUBK Model) and 1,200 to 3,500 mg/kg (Adult Lead Model). Using these ranges, and considering the previously developed site-specific residential cleanup level for lead of 450 mg/kg, Ecology set the soil-lead remediation level for historical and open space areas at 1,500 mg/kg. This decision was based on consideration of the range of calculated values and on best professional judgment regarding risk management at this site. Ecology thought than an exposure frequency of twice a week was appropriate, resulting in remediation levels of 1,575 and 1,750 mg/kg using the ratio approach (IEUBK model) and the Adult Lead Model, respectively.

3.6 Summary of Site Cleanup Levels and Remediation Levels

This chapter identified the soil cleanup levels and remediation levels that will be used to evaluate Site conditions based on future land use in Chapter 4. A summary of the future use scenarios and applicable cleanup and/or remediation levels is presented in Table 3-9.

Because more than one cleanup or remediation level was available for some constituents, some values were given precedence over others. In deciding which value to use for screening constituent concentrations, priority was given to levels that were specifically agreed upon with Ecology (Table 3-2 values). After these values, priority was given to the lowest available cleanup or remediation level applicable to the land use in question. A summary of the specific screening values used for commercial and golf course land uses, industrial land use, and historical and open space land uses are presented in Tables 3-10, 3-11, and 3-12, respectively.

Table 3-1 – Human Health Industrial Cleanup Levels

Constituent	MTCA Method C Industrial Cleanup Level (mg/kg)[(1)]
Explosives	
Monomethylamine Nitrate	28,350
Nitrobenzene	3,500
Nitroglycerine	4,080
2,4,6-Trinitrotoluene	7,000
Inorganics	
Aluminum	NC
Arsenic	90
Copper	130,000
Lead	NA
Mercury	1,050
PAHs	
Benzo(a)Anthracene	18
Benzo(a)Pyrene	18
Benzo(b)Fluoranthene	18
Benzo(k)Fluoranthene	18
Chrysene	18
Dibenzo(a,h)Anthracene	18
Indeno(1,2,3-c,d)Pyrene	18
Pesticides/PCBs	
Aldrin	7.7

Notes:
NA = No toxicity value for lead is available.
NC = Not of Concern: Concentration calculated was equivalent to a 100 percent concentration. Therefore, this constituent is not of concern through this exposure scenario.
[(1)]Industrial cleanup levels were calculated using equations and exposure factors identified for MTCA Method C (WAC 173-340-745), and toxicity factors identified in Table 3-7.

Table 3-2 – Site-Specific Soil Cleanup Levels[(1)]

Constituent	Concentration (mg/kg)
Mercury	24
TPH – Bunker C	7,600
Total DNT	3[(2)]
TNT	1.75

Notes:
[(1)]Information regarding these concentrations can be found in Appendix C.
[(2)]Includes the sum of the concentrations of 2,4-DNT and 2,6-DNT.

Table 3-3 – Exposure Factors Used to Calculate Site-Specific Soil Remediation Levels

Exposure Factor[(1)]		Exposure Scenario			
		Site-Specific Commercial Landscaper	Site-Specific Historical Areas	Site-Specific Open Space Areas	Site-Specific Golf Course Grounds-keeper
		Adult	Adolescent Child	Adolescent Child	Adult
Average Body Weight (kg)	ABW	70	47[(2)]	47[(2)]	70
Unit Conversion Factor (unitless)	UCF	1E+06	1.0E+6	1.0E+6	1.0E+6
Averaging Time (noncarcinogenic) (days)	AT_n	7,300	4,380	4,380	7,300
Averaging Time (carcinogenic) (days)	AT_c	27,375	27,375	27,375	27,375
Soil Ingestion Rate (mg/day)	SIR	200	200	200	200
Gastrointestinal Absorption Rate (unitless)	AB1	100%	100%	100%	100%
Exposure Frequency (days/year)	EF	52	104	104	52
Exposure Duration (years)	ED	20	12	12	20

Notes:
[(1)]Factors were derived in collaboration with Ecology (Ecology 1999a; Ecology 1999b). Memorandums outlining the derivation of these factors are contained in Appendix C.
[(2)]Value is the average weight of females and males between the ages of 6 and 18 (EPA, 1996a).

Table 3-4 – EPA Weight-of-Evidence Categories for Carcinogenicity[(1)]

EPA Group	Description of Group	Description of Evidence
Group A	Human carcinogen.	Sufficient evidence from epidemiological studies to support a causal association between exposure and cancer.
Group B	Probable human carcinogen.	B1: Limited evidence of carcinogenicity in humans from epidemiological studies; sufficient evidence in animals. B2: Sufficient evidence of carcinogenicity in animals and no or inadequate evidence in humans.
Group C	Possible human carcinogen.	Limited evidence of carcinogenicity in animals.
Group D	Not classified.	Inadequate evidence of carcinogenicity in animals.
Group E	No evidence of carcinogenicity in humans.	No evidence of carcinogenicity in at least two adequate animal tests or in both epidemiological and animal studies.

Notes:
[(1)]Carcinogenic classification group information was obtained from IRIS (EPA, 2001).

Table 3-5 – Toxicity Equivalency Factors (TEF) for Carcinogenic PAHs

Constituent	TEF[(1)]	Slope Factor (mg/kg-day)$^{-1}$
Benzo(a)pyrene	1.0	7.3
Benzo(a)anthracene	0.1	0.73
Benzo(b)fluoranthene	0.1	0.73
Benzo(k)fluoranthene	0.01	0.073
Chrysene	0.001	0.0073
Dibenz(a,h)anthracene	1.0	7.3
Indeno(1,2,3-cd)pyrene	0.1	0.73

Notes:
[(1)]Values were taken from the Supplemental Guidance for RAGS, Region IV Bulletins, Human Health Risk Assessment. EPA Region IV, Atlanta, GA 1995.

Table 3-6 – Oral Reference Doses and Carcinogenic Potency Factors Used in Remediation Level Calculations

Constituent	RfD (mg/kg-day)	Source of RfD	CPF $(mg/kg\text{-}day)^{-1}$	EPA Carcinogen Classification Group	Source of CPF

Pesticides/PCBs			
Aldrin	5	5	0.3

Notes:
NC = Not of Concern: Concentration calculated was equivalent to a 100 percent concentration. Therefore, this constituent is not of concern through this exposure scenario.
[(1)]Where remediation levels were calculated for both carcinogenic and noncarcinogenic effects, the value shown in the table is the lower of the two values.

[(2)]Value is site-specific background level for arsenic. This level was approved for use by Ecology (Ecology, 1999b).
[(3)]Values were derived by Ecology using the lead biokinetic models for children and adults (Ecology, 1999a).
[(4)]These levels represent levels based on direct contact with soil. The site-specific cleanup level of 24 mg/kg takes into account potential impacts to groundwater.

Table 3-8 – Site-Specific Input Parameters[(1)] and Results of the Adult Lead Model

Input Parameter	Units	Commercial Exposure Scenario	Golf Course Exposure Scenario	Industrial Exposure Scenario
$PbB_{fetal,0.95}$	ug/dl	10	10	10
$R_{fetal/maternal}$	(unitless)	0.9	0.9	0.9

Chapter 4 – Comparison of Site Concentrations to Cleanup and Remediation Levels

4.1 Introduction

In this chapter soil concentrations for each EU (identified in Chapter 2) are compared to cleanup and remediation levels identified in Chapter 3 to determine if the EU is in compliance with the MTCA three-fold criteria [WAC 173-340-740 (7)(d) and (e)]. As noted in Chapter 2, only those COPCs that were detected in at least one sample and had maximum concentrations that exceeded conservative risk-based screening criteria, were evaluated in this chapter of the risk assessment. In addition, EU COPC concentrations are compared to MTCA Risk-Based Criteria to evaluate if individual COPC concentrations and cumulative COPC concentrations in each EU meet risk-based goals.

4.2 Comparison of EU Soil Concentrations to Cleanup and Remediation Levels

4.2.1 MTCA Three-Fold Criteria

The soil concentrations in each EU were compared to the cleanup and remediation levels identified in Chapter 3 to determine if the concentrations of COPCs in each EU comply with MTCA three-fold criteria. The three-fold criteria are:

1. The maximum soil concentration for a COPC must be less than or equal to 2 times the site-specific COPC cleanup or remediation level.
2. The MTCA 95%UCL must be less than the site-specific cleanup or remediation level.
3. Less than 10% of individual soil concentrations shall exceed the site-specific cleanup or remediation level.

A modified version of this three-fold criteria is used when the cleanup level is based on a background concentration (i.e., historical and open space land use areas, for evaluation of arsenic only). The modified three-fold criteria are the following:

1. The maximum allowable concentration depends on the number of samples collected in the EU, the percentile used in development of the background concentration, and the coefficient of variability of the lognormal distribution (for EU samples). For relatively small sample sizes ($n < 30$) the criterion of no sample concentration more that two times the background concentration is suitable. In other cases, a higher factor of exceedance is required (requires consultation with Ecology).
2. The 95% UCL on the mean must be less than the background concentration.
3. For sample sizes less than 30, not more than 20% of the samples should exceed a background concentration that was based on the 90^{th} percentile background concentration. Ecology is consulted for other cases.

If an EU has any COPCs that exceed any element of the three-fold criteria outlined above, then the EU does not comply with MTCA, and is carried through to the FS for evaluation of remediation options. Results of this three-fold criteria evaluation are presented below.

4.2.2 MTCA Non-Cancer and Cancer Risk-Based Criteria

In addition to the three-fold criteria, MTCA identifies risk-based criteria for constituents as follows (WAC 173-340-708(4) and (5):

- The human health risk level for individual constituents may not exceed a hazard quotient of 1 or a cancer risk of one-in-a-million (1E-06) for historical and open space EUs. The human health risk level for individual constituents may not exceed a hazard quotient of 1 or a cancer risk of one-in-one-hundred thousand (1E-05) for the golf course, commercial and industrial EUs.
- The total risk level at the site, based on cumulative exposure to all constituents, may not exceed a hazard index of 1 or a cancer risk of 1 in 100,000 (1E-05).

If an EU exceeds these criteria, the EU does not comply with MTCA and is carried through to the FS.

4.2.3 Calculation of EU Soil Concentrations

Representative soil concentrations for each EU were calculated using SiteSTAT™ Statistical Software. Following combination of duplicate samples, statistical concentrations were calculated. The concentrations used for comparison to cleanup levels and remediation levels were the MTCA 95% Upper Confidence Limit (UCL) concentration and the maximum detected concentration.

The MTCA UCL concentration was calculated based on the following criteria:

1. The 95%UCL of the mean concentration for normally distributed data sets.
2. The Logarithmic 95%UCL (Log 95%UCL) of the mean concentration for all lognormally distributed and non-normally distributed data sets.
3. The maximum detected concentration in instances where the 95%UCL or Log 95%UCL exceeded the maximum detected concentration.

Before statistical calculations were performed, duplicate samples were combined to produce one concentration for each sample location. The decision rules used for combining duplicate samples were the following:

1. If both results were detected values, then the two values were averaged.
2. If one result was detected and one was not detected, then the highest detected value was used as the concentration for that sample location.
3. If both results were not detected, the highest detection limit value was used as the concentration for that sample.

The MTCA UCL calculations and other summary statistics calculated for the COPCs in each EU are presented in Appendix F. The statistical formulas used by the SiteSTAT are also presented in Appendix F.

4.3 Identification of EUs With COPCs That Exceed MTCA Three-Fold Criteria

Each EU was screened using the MTCA Three-Fold Criteria. Based on the results of this evaluation, the EU was determined to be in compliance or not in compliance with MTCA. Results of this evaluation are summarized below, organized by future land use category of the EUs. A detailed list of all screening results for each EU is presented in Appendix F.

EU evaluations of soils data over a depth interval of 1 to 15 feet are broad and they may not reflect realistic exposure scenarios. In addition, there is the potential to “dilute” exposure point concentrations. For remediation purposes, initial soil excavation depths will be determined based on individual characterization sample results and depths.

4.3.1 Commercial Land Use EUs

The compliance status of each EU is presented below in Table 4-1. As seen in this table, all EUs were out of compliance for at least one depth. Most criteria exceedances were found in surface soil, and arsenic and lead were the COPCs that exceeded the criteria most frequently.

4.3.2 Golf Course Use EUs

The compliance status of each EU is presented below in Table 4-2. As seen in this table, all EUs were out of compliance for at least one depth, and all but 2 EUs were out of compliance at both soil depth intervals. Arsenic and lead were the COPCs that exceeded the criteria most frequently.

4.3.3 Historical Use EUs

The compliance status of each EU is presented below in Table 4-3. As seen in this table, all EUs were out of compliance, and arsenic and lead were the COPCs that exceeded the criteria most frequently. There were no samples collected from subsurface soil, therefore all exceedances pertain to the top foot of soil.

4.3.4 Industrial Use EUs

The compliance status of this EU is presented below in Table 4-4. As seen in this table, the industrial EU passed the MTCA three-fold criteria.

4.3.5 Open Space Use EUs

The compliance status of each EU is presented below in Table 4-5. As seen in this table, all EUs were out of compliance in at least one depth. Most criteria exceedances were found in the surface soil, and arsenic and lead were the only COPCs that exceeded the criteria.

4.4 Identification of EUs that Exceed the MTCA Risk-Based Criteria

Each EU was screened using the MTCA Risk-Based Criteria. Based on the results of this evaluation, the EU was determined to be in compliance or not in compliance with MTCA. Results of this evaluation are summarized below, organized by future land use category of the EUs. Table 4-6 presents the individual hazard quotient and cancer risk for each COPC for each EU. Table 4-7 presents the total hazard index and the cumulative cancer risks for each EU.

4.4.1 Commercial Land Use EUs

When risk due to individual constituents was evaluated, only EU (COM 8) was out of compliance based on the cancer risk associated with arsenic. In addition, the individual non-cancer risk was out of compliance for TPH in one of the EUs. When cumulative risk was evaluated, one EU was out of compliance based on the cumulative non-cancer hazard index, and three were out of compliance based on the cumulative cancer risk.

4.4.2 Golf Course Use EUs

When risk due to individual COPCs was evaluated, all EUs were out of compliance based on the cancer risk associated with arsenic. In two EUs, the individual cancer risk was also out of compliance for benzo(a)pyrene. When cumulative risk was evaluated, nine of the EUs were out of compliance based on the cumulative cancer risk.

4.4.3 Historical Use EUs

When risk due to individual COPCs was evaluated, all EUs were out of compliance based on the cancer risk associated with arsenic. In addition, the individual cancer risk was out of compliance for aldrin in one of the EUs. When cumulative risk was evaluated, all of the EUs were in compliance.

4.4.4 Industrial Use EUs

The industrial EU was in compliance with the MTCA risk-based criteria.

4.4.5 Open Space Use EUs

When risk due to individual COPCs was evaluated, all EUs were out of compliance based on the cancer risk associated with arsenic. When cumulative risk was evaluated, all of the EUs were in compliance.

4.5 Summary of Screening Results

All EUs were screened against MTCA's Three-Fold Criteria and Risk Criteria. Using these criteria, all EUs except the industrial EU were not in compliance, and will require evaluation in the FS. More criteria exceedances were noted in the surface soil samples than in the subsurface soil samples. Arsenic and lead were the COPCs responsible for most criteria exceedances in the EUs.

Table 4-8 presents a summary of the compliance status of each EU. Figure 4-1 presents a map of the Site showing the compliance status of each EU with MTCA criteria arsenic and lead in the surface soil. Figure 4-2 presents a map of the Site showing the compliance status of each EU with MTCA criteria for arsenic and lead in subsurface soil.

Table 4-1 – Summary of COPCs that Exceed MTCA Three-Fold Criteria for Commercial EUs

EU	Soil Depth	COPCs Exceeding Criteria	Criteria Exceeded[1]	EU in Compliance with MTCA Three-Fold Criteria
COM 1	≤1 Foot BGS	Arsenic	10%; 2X	No
		Lead	UCL; 10%; 2X	
		TPH	UCL	
	>1 to ≤15 Feet BGS	Lead	UCL; 10%; 2X	No
COM 2	≤1 Foot BGS	Lead	10%; 2X	No
	>1 to ≤15 Feet BGS	None	None	Yes
COM 3	<1 Foot BGS	Arsenic	10%; 2X	No
		Lead	UCL; 10%; 2X	
	>1 to <15 Feet BGS	None	None	Yes
COM 4	≤1 Foot BGS	Arsenic	10%; 2X	No
		Lead	UCL; 10%; 2X	
	>1 to ≤15 Feet BGS	None	None	Yes
COM 5	≤1 Foot BGS	Arsenic	10%; 2X	No
		Lead	10%; 2X	
COM 6	≤1 Foot BGS	Lead	UCL; 10%; 2X	No
	>1 to ≤15 Feet BGS	None	None	Yes
COM 7	≤1 Foot BGS	Arsenic	10%; 2X	No
		Lead	UCL; 10%; 2X	
	>1 to ≤15 Feet BGS	2,4,6-Trinitrotoluene	UCL; 2X	No
		Lead	UCL; 10%; 2X	
COM 8	≤1 Foot BGS	Arsenic	UCL; 10%	No
		Lead	UCL; 10%; 2X	
	>1 to ≤15 Feet BGS	None	None	Yes
COM 9	≤1 Foot BGS	Arsenic	2X	No
	>1 to ≤15 Feet BGS	None	None	Yes

Notes:
COM = Commercial Areas.
[1]Criteria Exceeded: UCL = 95% Upper Confidence Limit concentration exceeds the cleanup levels and remediation levels. 10% = Ten percent of the COPC concentrations exceed the cleanup levels and remediation levels. 2X = Maximum concentration is greater than 2 times the cleanup levels and remediation levels.
[2]TPH 418.1 results above the cleanup levels and remediation levels were all associated with paraffin-coated cardboard except in one location where automobile parts were observed. Paraffin wax is generally regarded as biologically inert. Additionally, no CPAHs were detected in samples analyzed from this area. Thus there is no toxic fraction associated with paraffin-derived TPH concentrations.

Table 4-2 – Summary of COPCs that Exceed MTCA Three-Fold Criteria for Golf Course EUs

EU	Soil Depth	COPCs Exceeding Criteria	Criteria Exceeded[(1)]	EU in Compliance with MTCA Three-Fold Criteria
GC 1	<1 Foot BGS	Arsenic	UCL;10%; 2X	No
		Lead	UCL; 10%; 2X

OS 4	≤1 Foot BGS	- -	- -	- -	1.1E-06	- -

Notes:
COM = Commerical. GC = Industrial. HI = Historical. IN = Industrial. OS = Open Space.
Shaded values indicate risk levels that exceed MTCA's risk criteria. The EUs associated with these risks will be evaluated in the FS. Non-cancer hazards or risks for EUs and associated COPCs not presented in the table are below a HI of 1 and a cancer risk of 1E-06, respectively.
- - = Constituent has a hazard quotient less than 1, a cancer risk less than 1E-06, or is not a COPC for that EU.
(1)The background soil concentration for arsenic is 32 mg/kg. This Site-specific background concentration, in combination with the different exposure scenarios, results in cancer risks of 5.3E-06 for Commercial and Golf Course Land Use, 1.0E-05 for

Historical and Open Space and 3.6E-06 for Industrial. Consistent with MTCA, these areas would not be considered to be out of compliance unless the cancer risk exceeded these levels.

Table 4-7 – Cumulative Hazard Indices and Cancer Risks for Each EU

Evaluation Unit	Depth	Hazard Index	Cumulative Cancer Risk
COM 1	≤1 Foot BGS	1.4	2.2E-05

Chapter 5 – Uncertainty Analysis

5.1 Introduction

The results presented in this RA depend on a number of factors, including the availability of pertinent scientific information, standard RA practices, exposure assumptions, toxicity assumptions, and Ecology policy decisions.

Uncertainties are introduced into a RA because a range of values could be used for each assumption (i.e., parameter). Typically, more conservative (i.e., upper bound) values are generally chosen for each parameter, while other values (i.e., values closer to the central tendency) may be more representative of site-specific conditions. Choosing upper bound values for each parameter typically results in overly conservative risks that do not reflect site-specific conditions.

5.2 Uncertainties

Sources of uncertainty identified in the human health evaluation and professional judgment regarding the direction and magnitude of the impacts on the risk results are presented in Table 5-1. The direction and magnitude are those assumed to remain after any actions listed in the comment field have been implemented. This is done to qualitatively evaluate how much the risks and associated CLs might change if different values were used or if an alternative assumption or decision was made. In other words this uncertainty analysis provides a qualitative estimate of the confidence that the cleanup and remediation levels presented herein will be protective of the land-use and receptors on which they are based. The key study-specific uncertainties associated with the risk calculations and associated CLs and RLs are discussed in detail below.

5.2.1 Future Land Use

There is uncertainty associated with future land use at the Site. The RA assumed that future land use would include commercial, recreational (i.e., a golf course), historical, and open space for the purposes of developing RLs. If the Site was used for other purposes (e.g., residential) the RLs may not be protective. This uncertainty is very low because there are land use restrictions being imposed on the property to ensure that future land use is consistent with the assumptions made in the RA. Deed restrictions to limit Site uses will be imposed for different land uses including commercial, recreational (golf course), historical, industrial, and open space (Ecology, 2003). The City of DuPont zoning for the Site does not include any areas to be used for residential purposes (City of DuPont, 2001). An additional deed restriction will be required for the property inside the golf course footprint that limits this property to that sole use and places restrictions on activities that could disturb the cap/cover. In addition, the construction of an engineered cap/cover as part of the golf course placement areas also reduces the uncertainty that the property will be used for other purposes which would result in unaccounted for exposures to affected soil. Overall, the confidence that the future land-use will be consistent with what was evaluated in the RA is very high.

5.2.2 Exposure Factors

There is uncertainty associated with the exposure factors used to determine the CLs and RLs including the incidental soil ingestion rates. The default MTCA Method C scenario assumes that an adult industrial worker ingests 50 mg of soil each day. The CLs and RLs identified in this evaluation are based on the assumption that the commercial or golf course worker ingests 200 mg of soil each day. The uncertainty surrounding incidental soil ingestion rates is low due to the fact that a higher ingestion rate was used to develop the CLs and RLs.

5.2.3 Groundwater as a drinking water source

Drinking water was not evaluated in the RA because COPC concentrations in the RI indicated that, other than low DNT concentrations that were detected in 6 wells, groundwater is not a medium of concern. There is though, uncertainty associated with the use of groundwater as a drinking water source. Site groundwater is not currently used as a drinking water source. In the future, a deed restriction will be placed on the Site to restrict the use of groundwater to non-potable uses only, until such time as it meets

CLs. In addition, the capacity of off-Site drinking water supplies (which are located upgradient of the Site) is more than double the capacity needed for the projected population of DuPont through the year 2020 (WSNW, 2003). Therefore, the uncertainty associated with future groundwater use is low.

5.2.4 Arsenic Area Background Concentration

There is uncertainty associated with determining the background arsenic concentration at the Site. This area background concentration was determined after collecting twenty-three soil samples from unbiased locations outside of the Site consent decree boundary to define "Site background" soil quality in accordance with MTCA. The majority of samples were obtained from locations to the south and east of the Site. Ecology approved the use of the 32 mg/kg (i.e., ppm) as the area background concentration for arsenic in 1996. The confidence in this value being representative of area background concentrations is high.

5.2.5 Ecological Evaluation

There is uncertainty associated with ecological evaluation. Ecology performed an evaluation of the Site and determined that lead is the indicator compound for potential terrestrial ecological impacts. As part of this evaluation, Ecology determined that, based on site-specific information, the potential species groups of concern included ground-feeding birds and herbivorous small mammals. The soil screening level identified for lead by Ecology is 118 mg/kg, and is intended to be protective of wildlife, including birds and small mammals. This concentration is based on an exposure scenario which assumes that there are earthworms present in the contaminated soil and that robins are eating the earthworms. Overall, the confidence in this value being protective of ecological receptors is very high.

5.3 Conclusion

The MTCA rule, scientific information, site-specific factors, and the associated uncertainties were considered during the process of developing CLs and RLs. In general, when faced with uncertainty, more stringent assumptions were used in the evaluation so that the final result is CLs and RLs that are more health protective.

Table 5-1
Summary of Uncertainties in the Human Health Evaluation and Site-Specific Characteristics

Source of Uncertainty	Direction[(a)]	Magnitude[(b),(c)]	Comment
Key Uncertainties			
Future Land Use	+/-	0	Deed restrictions, zoning, and physical cap over the placement areas in the golf course together minimize the chance that future land use will be different than what was assumed in the RA.
Incidental Soil Ingestion Rate	+	2	The incidental soil ingestion rate that was used is 4 times higher than the MTCA default value.
Groundwater as a drinking water source.	+/-	0	The groundwater at the Site is not currently used as a drinking water source and deed restrictions will ensure that it is not used as a source in the future.
Area-wide arsenic background concentration	+/-	0	The area-wide concentration was determined according to the methodology prescribed in MTCA and ultimately approved by Ecology for use at the Site.
Ecological Evaluation	+	2	The screening concentration identified by Ecology was used as the cleanup level.
Other Uncertianties			
Quality of Analytical Data	+/-	0	Quality-assured data were used in the evaluation.
Identification and characterization of COCs present in soil.	+/-	0	The Site is well characterized with 21,933 soil sample analyses (5,182 samples), 12,038 groundwater sample analyses (283 samples), and 1,528 surface water sample analyses (344 samples).
Soil samples were not sieved through a < 250 mm screen.	-	1	EPA issued guidance recommending sieving soil samples for lead only. If this was done the lead concentrations in soil would be higher (i.e., the lead concentrations reported by the laboratory would be higher because lead is generally found in the finer soil fraction).
Exposure Frequency and Duration	+	1	MTCA default and Site-specific exposure Factors were used in the evaluation. The exposure frequency assumes that a commercial landscaper is working in the affected soil 2 days/week for 20 years.
Extrapolation from animal studies to human toxicity	+	3	U.S. EPA's conservative approach incorporating safety factors and upper-bound estimates was used in the evaluation.
Historical versus recent RA assumptions impact on CLs and RLs	+/-	0	Site-specific CLs and RLs have been developed over the course of many years and in some cases this results in differences in exposure scenarios and associated assumptions (see Appendix C) between older and newer agreements.

[(a)]Direction of Effect on Risk Calculations + = May result in risks that are overly conservative.
- = May result in risks that are not conservative.

[b]Magnitude of Effect on Risk Calculations
0 = Negligible impact on risk calculations.
1 = Small effect on risks calculations.
2 = Medium effect on risk calculations.
3 = Large effect on risk calculations.

[c]Direction and Magnitude values based on professional judgment.

Appendix A – Ecological Risk Assessment Summary

A.1 Introduction

In 1991, a Consent Decree between Ecology, Weyerhaeuser, and DuPont was signed. The MTCA regulations, as well as the Consent Decree, require that potential risks to human health and the environment be evaluated at the Site. This memo summarizes the qualitative and quantitative evaluations performed to evaluate the potential impacts to ecological receptors at the Former DuPont Works Site.

A.2 Nature and Extent of Contamination

Soil, groundwater, surface water (fresh and marine), and sediment were all potentially impacted from the activities of the Former DuPont Works. Constituent concentrations in these media (except for soil where there are no published standards) were compared to Federal and State environmental standards that are protective of the environment. No constituent concentrations in surface water and fresh water sediments exceeded any of the standards. Based on these comparisons and other factors such as diversity of species in fresh water sediments, it was determined that surface soil is the only medium of potential ecological concern (Hart Crowser, 1994).

Petroleum, DNT, TNT, mercury, arsenic, and lead were detected in soil at the Site. Petroleum, DNT, TNT, and mercury have been remediated and residual concentrations do not pose a risk to upland species of plants and animals. Human health standards for arsenic are protective of ecological organisms. Therefore, remediating arsenic contamination to meet human health standards will ensure protection for ecological receptors. The only remaining COPC for ecological receptors is lead.

The bulk of lead contamination in surface soil at the Site is, in general, localized around building foundations which will be remediated. The removal of soil around these foundations will reduce significantly the overall lead contamination Site-wide, and therefore, the overall risk to ecological receptors. Nevertheless, as currently envisioned, there will remain relatively small areas on the Site where either remediation or active land development are not planned. It is these areas, such as future Open Space and buffer areas, where the potential for exposure of ecological receptors to lead remains. The concerns raised by potential exposure to lead in these areas, and approaches to addressing these concerns is the focus of the following discussion.

A.3 Ecological Risk Assessment

A.3.1 General

Ecological risk assessment is a process that is used to estimate the likelihood and magnitude of harm to ecological receptors that results from exposure to one or more stressors. It is a tool that helps in the decision making process, hence the results of the ecological risk assessment are one of several considerations involved in making the ultimate decision as to what action might need to be taken at a site. In general, the ecological assessment process follows the concept of tiering. The assessment begins with a relatively simple screening process which allows the risk assessor to determine what receptors and what constituents are of concern. If the potential for ecological impacts are not found during this screening step, the assessment ends. If, however, there are potential ecological risks found, the assessment may progress to more complex and lengthy investigations. In this way, evidence is collected in a stepwise fashion allowing the decision maker to determine whether or not additional information is needed to make a scientifically supportable decision. Where sufficient information is available, such that the decision maker is no longer faced with a high degree of uncertainty, there may be no need for further assessment. There are at least two, perhaps more, approaches to ecological risk assessment: the top down approach, and the bottom up approach.

A.3.2 Top Down Approach

The top down approach takes a macro scale view of the existing conditions on-Site, including the plants, animals and habitats, and considers whether or not there are obvious signs of harm. The judgment as to whether or not harm is present is based on a comparison of the area of interest to a similar nearby area where the stressors of concern, such as metals, are not present. If the comparison suggests that there are no obvious signs of harm (i.e., the nearby site is not substantially different than the site of interest), the assessment can typically be stopped. The strength of the top down approach is that the "sum" of the functioning of the plants and animals is measured, and judged against a similar "sum" from a relatively clean area. It is analogous to "taking a big picture view of potential ecological risks". A weakness of this approach is that the resolution, or ability to see small things clearly, is not great enough to observe subtle, micro scale differences that might be present.

A.3.3 Bottom Up Approach

Conversely, the bottom up approach begins by measuring concentrations of constituents in important media, perhaps conducting toxicological tests on these media, and later attempting to integrate these measures into an estimate of ecological risk. The bottom up approach is analogous to viewing the individual trees in the forest and using that information to determine if there has been harm to the total forest. In contrast, the top down approach does not look at individual trees *per se*, but the total forest, to determine if there is potential harm. The strength of the bottom up approach is that discrete measurements of potential exposure and harm to individual components of the system are made, providing both a qualitative and quantitative estimate of potential risk. A weakness of this approach is that the overall functioning of the plants and animals, the "sum" of the system, may or may not match up with the bottom up information. That is, the overall system may be functioning appropriately even when individual components may not be.

At the former DuPont Works Site, both the top down and the bottom up approaches were applied as discussed below. Taken together, the two approaches complement one another and thus reduce the likelihood that either micro scale or macro scale problems are missed.

A.4 Site-Specific Ecological Studies - A Top Down Approach

A number of Site-specific qualitative and quantitative ecological studies have been conducted at the former DuPont Works Site. These included the following:

- **Biological Survey** – Terrestrial ecology studies were conducted from January 1977 through February 1978 to document existing conditions including the diversity and composition of plant and animal species (Melchiors and Motobu, 1978). The investigations included determining the species composition and extent of plant communities, bird, large and small mammals (e.g., mark-recapture trapping of small mammals), reptiles and amphibian populations.

- **Biological Resources Summary (The Weyerhaeuser Export Facility FEIS)** – This document provides a detailed summary of all previous biological investigation work regarding existing flora, fauna, and associated habitats at and in the vicinity of the Site (U.S. Army Corps of Engineers, 1982). The document also provides a series of maps and tables compiling all of the biotic information related to the Site. These data and observations support the conclusion that the former DuPont Works site is a relatively robust ecological area containing a diverse assemblage of plants and animals common to the Pacific Northwest.

- **Biological Resource Assessment** — To update the FEIS and previous work on Site, a biological resource assessment was performed in 1996 to re-evaluate the diversity of plant and animal species (Adolphsson and Associates, 1996). The studies compared highly contaminated areas within the Consent Decree boundary to similar uncontaminated off-Site reference areas by placing grids over the study areas and identifying and counting plants and wildlife. The majority of plants and animals observed were common to the on-Site and off-Site areas with small differences likely attributable to the higher degree of physical disturbance within the Consent Decree associated with various human activities, such as Site cleanup. There was no indication of plant or animal stress within the Consent

Decree areas. The study concluded that plant and animal populations appear to be healthy. No abnormal growth forms or patterns were observed in either plants or animals in the course of the study. Plant communities appear to be generally healthy and responding to changes in their physical environment that have resulted from initial cleanup and forest thinning activities. Wildlife also are relatively abundant on the Site, and at least some species were observed nesting and/or rearing young within the Consent Decree boundary. This comparative biological assessment found little differences between off-Site and on-Site communities; however, only gross impacts would have been noticed.

A.5 Site-Specific Ecological Studies - A Bottom Up Approach

Quantitative Site-specific studies have been conducted at the former DuPont Works Site as shown below.

- **Screening Soil Bioassays** — The Washington State Department of Ecology performed screening level bioassays on soil samples from the Site as part of its ongoing effort to develop methods to assess potential biological impacts (Norton and Stinson, 1993). The bioassays included (1) *Daphnia magna* percent survival; (2) Plant vigor based on biomass, percent germination, and percent survival; (3) Earthworm percent survival; (4) Fathead Minnow percent survival; (5) FETAX (Frog Embryo Teratogenesis Assay) percent survival, percent malformation, and mean growth of *Xenopus laevis* as presented in Table A-1. These bioassay results suggest that potentially detrimental effects were only observed at the high concentrations (the high concentration was 110,000 ppm). During 1999, 2000, and 2001 the areas with the highest lead concentrations (i.e., any sample where the lead concentration exceeded 4,100 mg/kg) have been removed from the Site (See the RI).

- **Draft Ecological Risk Assessment** — This study evaluated the impacts of Site-related COPCs on the environment (DERS and Hart Crowser, 1994). The assessment employed a food web model to quantify potential exposure of larger animals to contaminants in the soil and compared surface water and sediment constituent concentrations to standards. The assessment concluded that: (1) the potential risk to avian species under current Site conditions was minimal; (2) cleanup of lead to levels protective of human health would be reasonably protective of ecological receptors; and (3) that no potential risks to aquatic species were indicated under current Site conditions. Results of the food web modeling analysis indicated that no potential risk to large terrestrial mammals exists (deer and fox). Potential risks to herbivorous rodents (voles) were identified for some areas. A short coming of this study was that it did not take into account future land use (i.e., what habitat will remain after remediation and development).

- **Food Web Modeling** — A nationally recognized ecological risk assessor selected by Ecology and the PLPs initiated the development of a food web model which focused on highly exposed indicator species found at the site and taking into account the COPCs (Greg Linder, 1996). Ecology and the PLPs came to separate but similar conclusions that future land use was becoming an overriding factor with respect to potential ecological risk: hence this evaluation was no longer needed for making a final decision at the Site.

A.6 Conclusions

A variety of different studies, using both the top down and bottom up approaches to ecological risk assessment, have been conducted at the Site in order to provide information for making an ecologically-based, risk management decision. The conclusions that can be drawn from these studies include:

- The only constituent and medium of potential ecological concern is lead in surface soil. Ecology has performed an evaluation of the Site and determined that lead is the indicator compound for potential terrestrial ecological impacts. As part of this evaluation, Ecology determined that based on site-specific information, the potential species groups of concern included ground-feeding birds and herbivorous small mammals. The conclusion that lead is the only constituent of concern is supported by the fact that the value for arsenic (see Table 749-3 of MTCA) that is protective of wildlife is higher than any of the proposed soil arsenic remediation levels (except for the golf course placement area

remediation levels where an ecological exposure barrier will be present) that are protective of human health.

- Areas that will not be developed in the future are the only areas of concern for evaluating the potential impacts to ecological receptors.
- Lead contamination in surface soil at the Site is primarily localized around building foundations. The soil around these foundations will be remediated, reducing or eliminating exposure to lead.
- No differences in the numbers or condition of plants and animals in contaminated and uncontaminated areas were observed in the qualitative environmental evaluations at the Site. Generations of plants and animals have lived at the Site in the current state since the plant began operating in 1909.
- Screening bioassays performed at the Site suggest that some impacts might be expected to occur to ecological receptors of concern where concentrations of lead are greater than 500 mg/kg. With the exception of soils adjacent to the building foundations, there are minimal areas on site where this level of contamination is present.
- The potential ecological concerns at the site have diminished as development plans have become more concrete and as a result of the Interim Source Removals and Interim Corrective Actions.

As discussed previously, the results of the ecological risk assessment are but one of several pieces of information used by decision makers in reaching risk management decisions. In the case of the former DuPont Works Site, there are healthy and robust flora and fauna Site-wide. Remedial actions planned to protect human health will substantially reduce or eliminate further risk to ecological receptors in many areas of the Site, except in relatively small areas which will remain as Open Space or buffers. In these latter areas, based on the Site-specific data generated to date, the potential risk to ecological receptors is believed to be minimal. Two lines of evidence support this conclusion: 1) the presence of viable, healthy flora and fauna; and, 2) the comparatively small areas where soil lead is in excess of 500 mg/kg. Based on planned land use, it is also evident that these viable and valued habitats will remain so in the future. Overall, the incremental reduction of ecological risk that might be gained by active remediation in the Open Space and buffers is insufficient to outweigh the ecological costs that would result. Therefore, not pursuing additional remedial action in the Open Space and bugger areas will result in a net environmental benefit.

Table A-1 – Soil Bioassay Results

COPC Concentrations	Lead (mg/kg)	Results
Low	8.8	No significant effects.
Medium	490	Four of five bioassay results indicated no significant effects. FETAX results were different from the controls for percent survival and percent malformations.
High	110,000	Three of five bioassay results indicated effects different from the controls. These included percent survival in the *Daphnia magna* and Earthworms, and percent survival and percent malformations for the FETAX bioassay.

Appendix B – Evaluation Unit Sample Groupings

B.1 Introduction

This appendix presents all of the samples that were included in each evaluation unit. The short sample identifier, and the RI evaluation are presented for each sample. This provides a way to examine specific samples that are presented in the RI. Note that verification samples (i.e., data that were collected after soil was excavated) were excluded from the RA to ensure that the summary statistics were not biased low.

The following Tables are presented in Appendix B:

- Table B-1 – Commercial Area Samples <= 1 Foot BGS.
- Table B-2 Commercial Area Samples >1 Foot and <=15 Feet BGS.
- Table B-3 – Golf Course Area Samples <=1 Foot BGS.

Appendix C – Letters and Other Documentation of Site-Specific Determinations by Ecology

C.1 Introduction

The purpose of this appendix is to document the letters and other documentation of site-specific determinations that have been provided by the Department of Ecology.

This appendix contains letters and other documentation organized as follows:

- C.2 Arsenic and Lead Soil Cleanup and Remediation Levels
- C.2.1 Cleanup Levels and Remediation Levels for the Former DuPont Works Site
- C.2.2 Residential Soil-Lead Cleanup Level and Remediation Level for Former DuPont Works Site
- C.2.3 Non-Residential Remediation Levels at the Former DuPont Works Site
- C.2.4 Soil Arsenic Non-Residential Remediation Levels
- C.2.5 Arsenic in Soil – Area Background Levels
- C.3 DNT Soil Cleanup Level Protective of Groundwater
- C.4 Mercury Cleanup Levels Summary and Mercury/Lead Leaching Study
- C.5 TNT Soil Cleanup Level Protective of Groundwater
- C.6 TPH Soil Cleanup Level Protective of Groundwater
- C.6.1 Review of TPH Soil Cleanup Level Protective of Groundwater
- C.6.2 TPH/PAH Cleanup Level Summary

C.2 Arsenic and Lead Soil Cleanup and Remediation Levels

C.2.1 Cleanup Levels and Remediation Levels for the Former DuPont Works Site

STATE OF WASHINGTON
DEPARTMENT OF ECOLOGY

April 21, 2000

Dennis Clark
DuPont City Hall
303 Barksdale
DuPont WA 98327

Hello Dennis,

Re: Cleanup Standards and Remediation Levels for the Former DuPont Works Site

Thank you for spending time with me yesterday talking about land use and the cleanup site. I have enclosed a copy of three letters from Ecology to Weyerhaeuser and DuPont companies, per our discussion. The City of DuPont (former Mayor Shenkel) had received copies of these letters in the past.

Letter #1 (10/1/97) establishes a soil-lead cleanup standard for residential property at 450 parts per million (ppm). This cleanup standard is specific for the DuPont site and was developed using an EPA risk and exposure model and site-specific information. This cleanup standard was developed back when residential development was still being considered within Parcel 1.

Letter #2 (5/3/99) establishes soil-lead remediation levels for 4 different land use types:

1) golf course – 4,100 ppm
2) commercial – 2,100 ppm
3) Industrial – 1,000 ppm
4) Open space – 1,500 ppm

These remediation levels were developed using an EPA risk exposure model. The first three are based on adult worker exposure assumptions and the open space land use is based on an older child (7 to 18 years of age) exposure assumption. The soil-lead cleanup standard is still 450 ppm. That does not change. Any location where contaminants are left behind above the cleanup standard must be addressed through engineering and/or institutional controls, which includes deed restrictions.

Letter #3 (6/25/99) establishes soil-arsenic remediation levels for 3 different land use types:

1) golf course – 530 ppm
2) commercial – 60 ppm
3) industrial – 90 ppm
4) open space – to be determined

These remediation levels were developed using the standard Model Toxics Control Act risk formula and making adjustments to the exposure frequency parameter. Like the soil-lead remediation levels, the first three are for adult workers and the open space will be based on the older child exposure assumption. The open space soil-arsenic remediation level will probably be set at 32 ppm, the same average concentration identified in the twenty background soil samples collected outside the cleanup site boundary many years

ago. The cleanup standard for soil-arsenic is 20 ppm, based on the Model Toxics Control Act Method A number. The likely source of the elevated area-wide arsenic concentrations is the former ASARCO smelter in Ruston.

If you have any questions about the enclosed letters or want more detail on how the numbers (remediation levels and cleanup standards) were developed, please give me a call and I will provide you with that information.

On another subject, yesterday we discussed the City's year 2000 comprehensive land use plan being developed and the proposed location of future residential development. You were aware of the existing deed restrictions covering Parcels 1 and 2 of the cleanup site, which precludes residential development, now and into the future. You mentioned that conditions might change allowing for residential development within the cleanup site. Those changes included further cleanup might be conducted in the future, Weyerhaeuser might change its mind on the restrictive covenant, new technologies might be developed for easier and cheaper cleanups, etc. While I heard what you were saying yesterday, I am not sure that identifying deed restricted property for future residential development is a wise decision. The companies (Weyerhaeuser and DuPont) have stated to me, numerous times, that they have no intention of every allowing residences within the cleanup site due to long-term liability concerns. If you need additional copies of the restrictive covenants, let me know. A copy was provided most recently to former Mayor Shenkel in a letter dated 11/15/99. They are also on file with the Pierce County Assessor's office.

One last item. Sometime in the not too distant future, I would like to set up a meeting with you and Mayor Krill and whoever else is necessary from the City and Ecology (and the companies if appropriate) to discuss the DuPont Works Environmental Impact Statement before the final version is released. Before having the meeting, I need more time to go through all the comments Ecology received on the draft and determine how we will address them. The responses to the comments will be contained in a Responsiveness Summary. I am hoping that the final EIS will be ready for release in about 6 weeks.

If you have any questions about this letter or the enclosures, please give me a telephone call at (360) 407-6262. I understand that City Hall staff are now "on line". I can also be contacted at the following e-mail address mblu461@ecy.wa.gov .

Sincerely,

Mike Blum

Re: Residential Soil-Lead Cleanup Standard for Former DuPont Works Site

Dear Vern and Jack:

This letter is in reply to Tim Bingman's August 25, 1997, letter to me regarding site-specific inputs to the Integrated Exposure Uptake BioKinetic (IEUBK) model for determining residential soil-lead cleanup levels. I will also summarize our recent discussions about soil-lead cleanup in the future residential areas of the former DuPont Works Site and provide you with a decision regarding a site-specific soil cleanup standard for lead. As you know, Ecology is adopting the use of the Environmental Protection Agency's IEUBK model as a basis for setting site-specific residential cleanup levels for the protection of children. The Model Toxics Control Act (MTCA) Science Advisory Board has also concurred in the use of the model for making site-specific decisions.

Over the past several years, the Ecology Team has reviewed numerous submissions from Weyerhaeuser and DuPont Companies related to the topic of soil-lead cleanup standards, most of which dealt with the development of site-specific inputs into the IEUBK model. The most recent discussions on this topic have dealt with the soil-to-dust transfer coefficient input to the model. The standard default value for the soil-to-dust transfer coefficient is seventy percent (70%). We all agreed that 70% may not be a reasonable value to use for the Site, however, we needed adequate site-specific justification to change the default value.

Ecology used the services of Dr. Terri Bowers of Gradient Corporation to review the current literature for information that could provide a value for the soil-to-dust transfer coefficient that would be appropriate for the former DuPont Works Site. Terri provided Ecology with a report dated February 12, 1997 entitled Estimating the Soil-to-Dust Transfer Coefficient, and a memo regarding the Review of Leadville and Sandy Soil-to-Dust Relationships, dated June 24, 1997. On July 11, 1997, after initial review by the Ecology Team, I sent those same materials to Dr. Greg Glass for peer review. Greg is knowledgeable about risk assessment and has familiarity with the issue of soil-to-dust transfer at other cleanup sites. Greg responded on August 12, 1997, to my July 11 letter, which included a list of questions needing his response.

Based on the work by Terri and Greg, it appears that the 70% default value for the soil-to-dust transfer coefficient is an overestimate for this parameter at the former DuPont Works Site. This conclusion is mostly based on the fact that 1) the new homes to be constructed at the Site will not contain lead-based paint, 2) leaded gasoline will not be used in motor vehicles in the future, and 3) the future roads in the area will not have been impacted by past leaded gasoline use. Both consultants provided similar ranges of soil-to-dust transfer coefficients that would be defensible for use at the Site.

As noted in Tim's letter, Terri recommended using a soil-to-dust transfer coefficient on the order of 15 to 45%. Greg's opinion was that the range was 15 to 50% "with relatively high confidence", or 20 to 45% "with somewhat lesser but still appreciable confidence." The Ecology Team has selected 45%, a value from the upper portion of the soil-to-dust transfer coefficient range, to account for uncertainties in the underlying data, and its application at this site. The Ecology Team then applied the 45% transfer coefficient along with a site-specific ground water lead level of 2.0 ug/l to the IEUBK model. Using these inputs, the Ecology Team determined the residential soil cleanup level that would be protective of 95% of the child population (0 to 84 months of age) at a blood-lead level of 10 ug/dl.

Using the input parameters noted above, the IEUBK model estimates a soil-lead cleanup value of 443 mg/kg as protective. The proposed future development of the residential areas of the Site includes removal of the lead-contaminated topsoil prior to home construction, followed by replacement with clean topsoil and sod after the new homes are constructed. Considering the proposed future conditions at the Site, and the accuracy of the soil-to-dust transfer coefficient estimate, Ecology approves a risk management concentration of 450 mg/kg as protective of human health in the future residential areas at the former DuPont Works Site.

The Ecology Team recognizes that agreement on this issue marks a significant milestone in the project. We look forward to resolving the remaining technical issues including a soil-lead cleanup standard for the non-residential areas of the Site. If you or any of your team have any questions regarding this letter, please give me a telephone call at (360) 407-6262.

Sincerely,

Mike Blum

Dear Vern and Izzy:

Re: Non-Residential Remediation Levels at the Former DuPont Works Site

The Department of Ecology (Ecology) Team working on this project has made some decisions regarding remediation levels for lead in soil at the site. These remediation levels, formerly known as action levels, are for land uses other than residential. These remediation levels are levels at which we believe there is limited threat to human health and the environment based on assumed exposure scenarios and the implementation of various institutional controls and property deed restrictions. As a reminder, remediation levels are not synonymous with cleanup levels or cleanup standards.

I received Tim Bingman's letter of December 18, 1998 on the 21st of December. That letter proposed remediation levels for lead and arsenic in soils for the future golf course, industrial, commercial, and open-space land use areas. Remediation levels for arsenic in soil will be addressed in another letter in the near future.

First let me identify the site-specific soil-lead remediation levels to be established by Ecology and then explain how we arrived at those levels. Some levels are the same or slightly higher than what you proposed, while others have been reduced based on different exposure assumptions.

Table #1
Summary of Ecology-Derived Remediation Levels
For the Former DuPont Works Site

Future Land Use Area	Lead in Soil
Golf Course	4,100 ppm
Commercial	2,100 ppm
Industrial	1,000 ppm[1]
Open Space	1,500 ppm

[1] Use same soil-lead remediation level as in Parcel 2 as opposed to Adult Lead model value of 1,963 ppm.

Tim Bingman and I made a presentation to the Model Toxics Control Act Science Advisory Board in November 1998 regarding the use of EPA's Adult Lead model to develop soil-lead remediation levels at cleanup sites in Washington. They gave their approval to the use of the model and the model's guidance document. As proposed in Tim's December 1998 letter, Ecology concurs with the use of the region-specific baseline blood-lead level (Washington State) and blood-lead geometric standard deviation (Western U.S.); 1.36 micrograms per deciliter (ug/dl) and 1.81, respectively. Table #2 below outlines the specific input parameters to the Adult Lead Model equation and the values selected by Ecology as appropriate for the former DuPont Works site.

Table #2 - Adult Lead Model Input Variables

Description of Input Variables	Equation Variables	Units	Commercial Exposure Scenario	Golf Course Exposure Scenario	Industrial Exposure Scenario
95th Percentile PbB (Blood Lead) in Fetus	$PbB_{fetal,0.95}$	ug/dl	10	10	10
Fetal/Maternal PbB Ratio	$R_{fetal/maternal}$	----	0.9	0.9	0.9
Biokinetic Slope Factor	BKSF	ug/dl per ug/day	0.4	0.4	0.4
Geometric Standard Deviation PbB	$GSD_{i,adult}$	----	1.81	1.81	1.81
Baseline PbB	$PbB_{adult,0}$	ug/dl	1.36	1.36	1.36
Soil Ingestion Rate	IRs	g/day	**0.200**	0.100	0.050
Absorption Fraction	AFs	----	0.12	0.12	0.12
Exposure Frequency	EF	days/year	52	52	**219**
Averaging Time	AT	days/year	365	365	365
Remediation Levels	PbS	mg/kg	**2,067**	4,134	**1,963**

(The values in **bold** are different from those proposed by Weyerhaeuser and DuPont)

The Ecology Team considered the input variables proposed by the companies. The choice of input variables is a risk management decision and is based on best professional

judgement, unless of course site-specific data is available. We decided that the above variables should be used for the following reasons:

1. The golf course cap is an engineered containment facility. As such, greater controls, both physical and institutional, can and will be implemented.

2. The commercial areas worked in by landscapers may not have the same protective measures as the golf course, nor will workers necessarily be aware that the areas they are working in are part of a hazardous waste site with possible residual soil contamination. Draft EPA Region 10 guidance recommends 200 mg/day as an adult soil ingestion rate for occupational exposures involving soil contact activities. The golf course worker will be better informed about the site being a hazardous waste containment facility, and as such, will be required to take better precautions to reduce exposure to (ingestion of) contaminated soils, as compared to commercial area landscape workers. That is why we have chosen 100 mg/day as the appropriate ingestion rate for the golf course worker versus the 200 mg/day recommended by EPA. To further reduce exposures, the companies have stated that the irrigation lines at the golf course will be located either in clean backfill or above the contaminated soil layer. This can be ensured through course design, which will occur with Ecology oversight.

3. The frequency of contact for the industrial land use scenario was changed to match the default value in the Adult Lead Model. The 40% value (146 days) from the Model Toxics Control Act soil/carcinogen risk formula is not appropriate for use in this model.

4. The exposure frequency for the golf course worker is set at 52 days per year. As noted in Tim's letter and the attached appendices, the Ecology Team agrees that an appropriate estimate for the exposure frequency is 36 days per year (possibly even less, depending upon site layout and engineering controls), however a minimum value of 52 days per year must be used to avoid "violating" the adult lead model assumptions (steady-state blood lead levels).

5. The industrial land use remediation level has been reduced from 1,963 to 1,000 ppm to match the Model Toxics Control Act Method A industrial cleanup value established for Parcel #2 in the 1997 Cleanup Action Plan, as recommended by the companies.

6. The Adult Lead Model is set to be protective of the fetus of a pregnant woman, the most susceptible sub-population. To be protective of an adult (non-pregnant worker), the remediation levels for each land use scenario would be considerably higher. The target blood lead level of 10 ug/dl was established to be protective of the fetus as well as very young children.

Next let me describe how the Ecology Team selected 1,500 ppm as the soil-lead remediation level for open space areas. The companies proposed a ratio approach based on using the results of the site-specific residential cleanup levels established for the site - 450 ppm. That level was determined using EPA's Integrated Exposure Uptake Biokinetic (IEUBK) Model and is based on young children up to 84 months old. The most frequently exposed population in the open space areas, which are the natural areas and not developed parks or ball fields, would most frequently be the "older child". The older child is somewhere between 7 and 18 years of age. There is no specific age at which the older child's biokinetics responds similarly to an adult, especially in terms of absorption of lead. Most researchers agree that the younger child absorbs lead more readily than the older child or the adult. So, how does one develop a remediation level when no soil-lead exposure model exists for the older child? As noted above, the companies proposed an "exposure ratioing" approach that results in a remediation level of 3,159 ppm. That level is based on a once a week exposure compared to daily exposure at the residential cleanup level of 450 ppm. [(7 days/week ÷ 1 day/week) * (450 ppm) = 3,150 ppm] (The difference between Ecology's (3,150 ppm) and the companies' (3,159 ppm) remediation level is the minor difference between the use of a 1 day per week ratio versus a 52 days per year ratio.) The goal of the IEUBK model is to protect 95% of the children from exceeding a blood lead level of 10 ug/dl. Exposure frequencies of 2 and 3 days per week result in remediation levels of 1575 ppm and 1050 ppm respectively.

Using the Adult Lead Model to develop remediation levels for the older child is another approach. Using the adult lead model with exposure frequencies of 1, 2, and 3 days per week results in remediation levels of 3512 ppm, 1756 ppm, and 1171 ppm respectively.

Under all scenarios, the maternal/fetal blood lead ratio was eliminated and the goal of protecting 95% of the older child population from exceeding 10 ug/dl blood lead level was retained. As a point of reference, the adult blood lead level goal ("not to exceed" value) is based on industrial exposures and is generally set at 25 to 30 ug/dl for males. The geometric standard deviation and baseline blood lead level input remained unchanged.

The two approaches yield ranges of approximately 1,050 to 3,150 ppm and 1,200 to 3,500 ppm. The site-specific residential cleanup level for lead in soil is 450 ppm. The value for open space proposed by the companies was 3,159 ppm. The upper bound is dependent on the assumed exposure scenario and the input parameters. The Ecology Team has set the soil-lead remediation level for the open space as 1,500 ppm based on consideration of the above criteria and best professional judgement regarding this risk management decision. As you know, most of the open space areas are relatively clean, with some isolated areas of elevated contaminant concentrations (e.g., hot spots). The Team carefully thought about exposure frequency and considered twice a week as appropriate, resulting in remediation levels of 1575 and 1750 ppm using the ratio approach and the adult lead model, respectively. In making this risk management decision, the Ecology Team also considered the older child transporting lead

contamination back home on their shoes and clothes, which could create additional exposures to themselves and/or to other/younger children in the house.

One last issue. The Toxics Cleanup Program is currently in the midst of a major change to the Model Toxics Control Act. The program is also wrestling with some significant issues related to arsenic in soil. Those things will affect how we address arsenic remediation levels at the former DuPont Works site. Due to the above changes as well as ongoing discussions with the companies, the Ecology Team is addressing arsenic issues separate from lead. Site-specific arsenic remediation levels will be established in a letter that will follow in the near future.

In conclusion, the Ecology Team has spent considerable time considering your remediation levels proposal contained in Tim Bingman's December 1998 letter. We feel that the input variables chosen by Ecology are reasonable and protective. As stated earlier in this letter, we feel that the golf course cap/containment facility provides the best physical and institutional controls on future exposure to contaminated soils. As in the past, this project's cleanup Team (Weyerhaeuser, DuPont, and Ecology) is once again breaking new ground, this time with use of EPA's Adult Lead Model. These innovative approaches take more time to evaluate than following the well-worn path others have used. We are comfortable that the soil-lead remediation level decisions Ecology has made will stand up to public scrutiny, when we get to that point. There is adequate conservatism built into the assumptions used, while not being overly conservative.

If you have any questions regarding this letter or the calculations and risk management decisions regarding remediation levels, please give me a call at (360) 407-6262.

Sincerely,

Mike Blum

Dear Vern and Izzy:

Re: Soil Arsenic Non-Residential Remediation Levels

The Department of Ecology (Ecology) Team received Tim Bingman's letter dated June 1, 1999, regarding the development of non-residential remediation levels for arsenic in soil at the former DuPont Works cleanup site. Tim's letter was received on June 2nd. The letter incorporated the issues we had discussed during our May 25, 1999, meeting at the site as well as some issues related to open space land use areas that were not discussed that day. The Ecology Team (Dan Alexanian, Kelly Susewind, and myself) is in concurrence with the proposed remediation levels with the proviso that engineering controls will be used to limit exposure to golf course workers. The assumed exposed individual based on that particular land use is the basis for the associated remediation level, which are as follows:

PROPOSED LAND USE	POTENTIALLY EXPOSED INDIVIDUAL	REMEDIATION LEVEL
Commercial	Adult landscape worker	60 milligrams per kilogram (mg/kg) or parts per million
Golf Course	Adult golf course worker	530 mg/kg
Industrial	Adult worker	90 mg/kg

I have included the specific input variables as an attachment to this letter, which I copied directly from Tim's letter.

The open space land use areas do not have a proposed soil-arsenic remediation level. A "combination of engineering solutions" was proposed in Tim's letter that includes some soil removal and some in-place capping/containment. Ecology believes that the soil-arsenic remediation goal for the open space areas should be 32 mg/kg, which is the same as the area background for the site. In working towards that goal, Ecology also wants to ensure that the net environmental benefit of any proposed action is positive. We have talked numerous times about the issue of net environmental benefit of cleanup in open space areas.

That includes the impacts of either excavation and/or capping of contaminated soils versus leaving the contaminants in place and not disrupting the environment. Our teams have collectively reached a verbal understanding of generally what needs to occur and why. What is lacking is that reasoning written down in a more formal manner. Your request needs to be a "stand alone" document, like most of the past proposals you have submitted. When someone outside our respective team reads your request letter as well as Ecology's response, they should have a clear understanding of the issues and the reasoning behind your request and Ecology's response.

In general, as well as specifically in terms of the open space areas, a goal of Ecology and the companies is to safeguard water quality in Sequalitchew Creek, Old Fort Lake and Puget Sound. A couple protective measures includes limiting work on steep slopes and creating erosion problems as well as saving trees and habitat where possible - especially in the designated open spaces. As we have discussed, specific open space locations needing remediation will be made on a case by case basis. As discussed in Tim's letter, remediation of arsenic impacted soils along the narrow gauge railroad corridor, within the Sequalitchew Creek canyon open space area (Open Space #1), will be capped with gravel. That action will serve as both a physical barrier to exposure as well as creating part of the planned walking trail down the Sequalitchew Creek canyon to Puget Sound. Your request letter should discuss why other more permanent options are not feasible, such as excavation and off-site disposal or on-site treatment, and why those options may cause more harm than good.

I would like to point out a few things about the gravel capping approach for the narrow gauge railroad corridor mentioned in Tim's letter. There are some difficulties, or potential opportunities, depending on how one looks at it. In reviewing the existing narrow gauge sampling data within Open Space #1, it appears that there were four or five samples collected (RR-596, RR-597, RR-598, RR-599, and LR-68), all of which exceeded the area background arsenic concentration of 32 ppm. Therefore, that entire section of track would need to be covered with gravel. Tim's letter proposed a "six-inch thick layer of gravel extending five feet on either side of the railroad centerline". Why five feet? That proposal needs to be justified. The railroad corridor data from the site includes samples collected along the centerline and some samples 25 and 50 feet on either side of the centerline. Further "downstream" of Open Space #1, there were no samples collected along the narrow gauge railroad. That area is outside the consent decree boundary. When we established the boundary, it was based on soil-lead contamination. At that time, 1991, arsenic was not known to be a contaminant at the site. Do you have any information about whether that section of track was sprayed with arsenic-based herbicides in the past? I understand that there is a mitigation agreement between the City of DuPont (City) and Lone Star Northwest (Lonestar) regarding conversion of a portion of the railroad corridor to a trail along Sequalitchew Creek canyon. I have not yet seen or read that agreement, so I do not know the details. I understand that section of track/railroad corridor is to be covered with wood chips. Is there a possibility of working with the City and Lonestar to pave or gravel the entire railroad corridor down the canyon, thereby addressing both remediation concerns and gravel mining mitigation at the same time? Also, gravel would make a better (more permanent) path than wood chips.

A couple other final comments and questions. In Open Space Area #3, the buffer zone along the southern and eastern site perimeter, a 75-foot strip of vegetation will be left. Does the 75-foot border start at the fence line or the inside edge of the existing dirt road? If the existing dirt road is part of that open space, do you think vegetation will be planted or will it in be naturally re-vegetated? Capping in the open space areas will reduce the exposure potential by cutting off or reducing that exposure pathway. It does not however reduce the contaminant concentration remaining, as mistakenly stated in Tim's letter.

It is Ecology's desire to work with the companies to protect the open spaces and the ecological resources to the extent practicable. If you have any questions regarding this letter or what the Ecology Team is expecting regarding the open space areas and additional net environmental benefit evaluation, please give me a call at (360) 407-6262.

Sincerely,

Mike Blum

Attachment #1

Bases for Input Variables Used to Calculate Non-Residential Arsenic Remediation Levels

A description of the major inputs to the MTCA intake equation, as well as an explanation for values used in calculating arsenic remediation levels, is described below.

RISK – Represents the acceptable incremental carcinogenic risk level. In the case of all three land use scenarios, this value is 1×10^{-5}. The 1×10^{-5} value is codified for industrial settings in the MTCA at WAC 173-340-745 (4)(a)(iii)(B). The policy to use a value of 1×10^{-5} for the commercial areas (which is also applicable to the golf course area) was established by Pete Kmet in a memorandum dated February 14, 1995.

ABW – Describes the average body weight for the potentially exposed population under consideration. For the commercial, golf course and industrial areas, this would be an adult, with an average body weight of 70 kg.

LIFE – Represents the duration of a human lifetime over which the exposure is averaged. Per WAC 173-340-740 (3)(a)(iii)(B), the default value is 75 years.

UCF – This is a unit conversion factor of 1×10^{6} applied to calculate remediation levels in units of mg/kg.

CPF – This describes the carcinogenic potency factor for arsenic. The current value for arsenic in USEPA's IRIS database is 1.5 $mg/kg/day^{-1}$.

SIR – Represents the soil ingestion rate for exposure to site soils. Ecology has recommended a value of 200 mg/day for establishing remediation levels for the future commercial land use area. A value of 100 mg/day has been recommended by Ecology for use in the golf course area, in light of the training that golf course workers receive. The 50 mg/day value is the MTCA default for industrial exposure.

AB – Represents the gastrointestinal absorption rate. DuPont and Weyerhaeuser believe that current scientific evidence supports the value of 0.4 (40%) as specified for arsenic in the MTCA "Cleanup Levels and Risk Calculation" document. However, we understand that Ecology anticipates modification of this value as a matter of policy to 100% absorption in the near future. Hence, the updated value has been used in these calculations.

DUR – Describes the duration of exposure in years. The value of 20 years for industrial exposure is the MTCA default value. The value of 20 years for the commercial and golf course areas is specified in Pete Kmet's memorandum of February 14, 1995, and is appropriate, given that adults represent the potentially exposed population.

FOC – Represents the frequency of contact term. Frequency of contact, as used in the MTCA equation, is calculated from the exposure frequency for the commercial, industrial and golf course land use scenarios. The value of 52 days/year represents a once-per-week exposure in the commercial area. The 12 days/year value for the golf course worker is based on a combination of interviews of golf course managers describing the approximate frequency for subsurface soil exposure during maintenance activities, and the anticipated use of clean backfill material around irrigation main lines at the golf course. The 40% frequency of contact for the industrial areas (corresponding to an exposure frequency of 146 days/year) is the MTCA default for industrial exposure.

C.2.5 Arsenic in Soil – Area Background levels

STATE OF WASHINGTON

DEPARTMENT OF ECOLOGY

P.O. Box 47775 • Olympia, Washington 98504-7775 • (360) 407-6300

March 11, 1996

P.O. Box 100
DuPont, WA 98327-0100

Mr. Jack Frazier
The DuPont Company
DuPont Chemicals, B-12230
1007 Market Street
Wilmington, DE 19898

Dear Vern and Jack:

Re: Arsenic in Soil - Area Background Levels - 32 Parts Per Million

This letter is to confirm our recent discussions about arsenic and the area background soil concentration that has been determined for the former DuPont Works Site. The Ecology Team has reviewed the data submitted in the draft Remedial Investigation (RI) report dated December 22, 1994, as well as a separate but similar undated 6 page paper entitled Area Background Arsenic Levels, both prepared by Hart Crowser. The conclusion reached by Hart Crowser is that the area background concentration is 32 mg/kg, following the Model Toxic Control Act (MTCA) regulations and associated guidance. The Ecology Team concurs with the determination of 32 parts per millions (ppm) as the area background concentration for arsenic in soil.

So, what does that 32 ppm determination mean in terms of site cleanup decisions? Ecology will not require any soil cleanups to be more stringent than 32 ppm, irrespective of land use. Site-specific cleanup standards and action levels for arsenic in soil have not been determined for this Site. You and your consultant, Sciences International, Inc., are currently working on a proposal to reassess the toxicity of arsenic, which may affect soil-arsenic cleanup levels for this Site. As a point of reference, at this point in time, the arsenic cleanup standard for the Site would be 32 ppm for residential land use and 200 ppm for industrial land use. Cleanup standards for other land uses such as commercial, recreational, open space, etc., would fall somewhere in between 32 and 200 ppm.

It is interesting to note a couple points about natural background concentrations of arsenic in surficial soil throughout Washington State. Sampling conducted by the United States Geological Survey, under a project[1] through Ecology, found the following results:

Areas of the State	Arsenic (GFAA[2] Lab Method)	Arsenic (ICP[3] Lab Method)
Puget Sound Area	7.30 mg/kg	22.80 mg/kg
Western Washington	6.37 mg/kg	46.21 mg/kg
Statewide	6.99 mg/kg	41.81 mg/kg

[1] Ecology, Natural Background Soil Metals Concentrations in Washington State October 1994, publication #94-115
[2] Graphite Furnace Atomic Absorption (GFAA), EPA Methods 7060 & 7740
[3] Inductively Coupled Plasma (ICP) Atomic Emission Spectroscopy, EPA Methods 3050 & 6010

Mr. Vern Moore
Mr. Jack Frazier
March 11, 1996
Page 2

As shown above and noted in the 1994 Ecology report, using GFAA for arsenic analysis allows one to achieve lower detection limits than using ICP methods and is therefore more accurate at lower levels. ICP analysis can produce higher values for arsenic because of iron (iron acts as an interferant and is difficult to correct for when analyzing for arsenic using ICP Methods).

One last point that we all need to keep in mind. All future characterization and confirmation/verification analyses should use the same analytical methods that we have been using to date. We need to ensure all the data, past and future, is comparable. The original Quality Assurance Project Plan identified GFAA as the primary methodology for soil-metals analyses, with the exception of mercury.

If you have any questions regarding this letter and area background levels for arsenic in soil, please give me a call at (360) 407-6262.

Dear Vern and Jack:

Re: Acceptance of Two Issue Papers - 1) Determination of a DNT Soil Cleanup Level Protective of Groundwater, and 2) Impracticability of Groundwater Treatment

The Ecology Team reviewed the two latest drafts of the above mentioned documents for the Former DuPont Works Site as drafted by Hart Crowser. We find them to be acceptable and agree with the conclusions contained in those issue papers. No further rewrites are necessary nor should other changes be made to them prior to their incorporation as is into the final draft remedial investigation and feasibility study reports.

The Ecology Team is still reviewing numerous other issues and/or papers submitted or raised at previous meetings. Some of those issues are listed below. Of course, this is not an exhaustive list:

1) The paper entitled Summary - Potential Leachability of Lead and Arsenic in Golf Course Use Areas.
2) The question of leachability of Bunker C in Area 8 and whether the excavations can be backfilled.
3) Exposure units.
4) Arsenic background concentrations.
5) Arsenic cleanup standards and Sciences International, Inc., work.
6) MTCA Lead cleanup standards using the IEUBK model.
7) Site-specific lead bioavailability study.
8) Statistics
9) Ecological risk assessment and Greg Linder's work, just to name a few.

The Ecology Team is close to finalizing or making a decision on more than half of the above mentioned items.

If you have any questions regarding this letter, please give me a call at (360) 407-6262.

Sincerely,

Mike Blum

**DETERMINATION OF A DNT SOIL CLEANUP LEVEL
PROTECTIVE OF GROUNDWATER
FORMER DUPONT WORKS SITE
DUPONT, WASHINGTON**

Conservative evaluations of Site conditions indicate that a soil cleanup level for dinitrotoluene (DNT) of 3 mg/kg provides a high level of protection to groundwater at the Former DuPont Works Site (Site), assuming a hypothetical drinking water exposure.

Soil Cleanup Level Determination

The DNT soil cleanup level for drinking water protection was calculated probabilistically using the following method with conservative input assumptions:

soil cleanup level (mg/kg) = drinking water screening level (mg/L) * DAF (unitless)* K_d (L/kg) (1)

where

- the MTCA drinking water screening level for DNT is 0.00013 mg/L;
- DAF is the dilution/attenuation factor, which, for this evaluation, considered only dilution occurring as a result of natural mixing of infiltration with groundwater flow in the upper ten feet of Site aquifers; and
- K_d is the Site-specific DNT soil:water desorption coefficient determined from toxicity characteristic leaching procedure (TCLP) testing.

Equation (1) was run as a Monte Carlo simulation using Crystal Ball software, a forecasting and risk analysis add-on to Excel software. In the Monte Carlo simulation, equation (1) was solved 5,000 times using input parameter values picked randomly from probability distributions for K_d and DAF developed from Site-specific and regional information. The soil cleanup level results determined from the 5,000 iterations were compiled automatically into a probability distribution for which percentiles were generated. The 5th percentile value of that distribution represents a conservative estimate of a DNT soil cleanup level protective of Site groundwater under a hypothetical drinking water exposure scenario, i.e., there is 95 percent probability that a 3 mg/kg DNT soil cleanup level is protective of Site groundwater.

Cleanup Level Determination Assumptions

Because the DNT drinking water screening level was set as a constant in equation (1), assumptions were required only for the desorption coefficient (K_d) and DAF in determining a Site-specific soil cleanup level for DNT. The assumptions follow, and supporting information is provided in Attachment A.

Desorption Coefficient (K_d) for DNT. A Site-specific DNT soil:water desorption coefficient (K_d) was developed from TCLP results for 27 samples of Site soils. Informal discussions with the Washington State Department of Ecology (Ecology - Charles San Juan, personal communication, August 1995) indicate that TCLP is an acceptable method for obtaining desorption coefficient (K_d) estimates for organic compounds like DNT. Statistical evaluation of the K_d values indicates that they are lognormally distributed with a geometric mean of 20 L/kg and geometric standard deviation of 4.0 L/kg (see Table 1). The geometric standard deviation was decreased, such that the K_d probability distribution in the Monte Carlo simulation was constrained within the range of Site-specific values determined from TCLP testing. Without the adjustment of standard deviation, the modeled distribution projected well outside the range of measured values. The resulting K_d probability distribution extends from 2 to 190 L/kg (refer to page A-5 in Attachment A [values are in natural logs]), which encompasses all but the single lowest and single highest measured values (0.2 and 248 L/kg, respectively; see Table 1). Figure 1 provides a comparison of the modeled and measured probability distributions for K_d for DNT at the Site.

Dilution/Attenuation Factor (DAF). A dilution/attenuation factor (DAF) represents the reduction in concentration occurring during transport from the bottom of the impacted soil, through the vadose zone, to a monitoring point within the aquifer. The DAF includes dilution (e.g., mixing and dispersion) and attenuation (e.g., sorption, reaction, and degradation) occurring both in the vadose zone and in the aquifer. Consistently low DNT concentrations detected in Site monitoring wells located downgradient of areas where high DNT soil concentrations existed prior to interim source removal may suggest a large DAF for DNT at the Site.

For this evaluation, the DAF was limited to reflect only the natural dilution occurring in the upper ten feet of Site aquifers (i.e., all other dilution/attenuation processes were not considered). A ten-foot thickness of aquifer was selected as a conservative assumption based on protecting a hypothetical drinking water exposure. Groundwater discharging at the sea level seeps is not a potential drinking water source because of salinity (per WAC 173-340-720-[1][a][ii][B]; refer to Hart Crowser, 1994), and the

seeps are submerged daily by high tides. DNT was not detected in freshwater springs discharging to Sequalitchew Creek in four years of monitoring. Therefore, a drinking water exposure at the Site could only occur by constructing and operating a water supply well. In practice, a well would be installed as far below the water table as practical to provide for pump clearance and well losses, and to maximize available drawdown and thus well yield. A well completed deeper in the aquifer would draw water from a greater aquifer thickness, and thus allow greater mixing to occur. Considering dilution in only the upper ten feet of aquifer, corresponding to a small (ten-foot) well penetration, provides an additional conservative assumption in developing a DAF for the Site. Because this DAF considers only physical mixing of the infiltration water with groundwater in the aquifer, and does not include any chemical attenuation processes, it is applicable for all constituents at the Site.

The dilution factor represents the ratio of the groundwater flux (through a one-foot-wide by ten-feet-thick vertical cross sectional area of aquifer) to the infiltration flux (through a one-square-foot surface area). The assumptions used in estimating the aquifer flux and infiltration flux in the Monte Carlo simulation are listed below.

Infiltration flux was calculated as follows:

$$Q_i = (P - ET - RO) * A_{surface} * (\text{foot}/12 \text{ inches}) * (7.48 \text{ gal}/\text{ft}^3) * (\text{year}/525{,}600 \text{ min})$$

where

Q_i = infiltration flux in gpm;
P = precipitation in inches/yr;
ET = evapotranspiration in inches/yr;
RO = runoff in inches/yr;
$A_{surface}$ = surface area of 1 ft^2; and
The last three terms on the right side of the equation are units conversion factors as indicated.

- For the Monte Carlo simulation, precipitation was assigned a triangular distribution with minimum, most likely, and maximum values of 25.6, 37.8, and 50.0 inches per year, respectively, based on annual precipitation data from the Tacoma station. The measured annual values ranged from 24.9 to 46.9 inches per year. The average (37.8 in/yr) and standard deviation (6.1 in/yr) of the annual precipitation values were calculated, and the average value was used as the most likely value in the triangular distribution. The average plus and minus two standard deviations represented the maximum and minimum values, respectively, in the distribution (see page A-5 in Attachment A).

- Evapotranspiration was assigned a uniform distribution with minimum and maximum values of 19.9 and 20.1 inches per year, respectively, based on estimated evapotranspiration values from the Tacoma (19.9 inches/yr) and Puyallup (20.1 inches/yr) stations reported in Washington State University (1968) (see page A-5 in Attachment A).

- Runoff was assigned a uniform distribution within minimum and maximum values of 0 and 5.0 inches per year (see page A-6 in Attachment A). Although regional measurements of surface runoff were not obtained (data are rarely measured), Thorthwaite and Mather (1957) suggest 10 percent of precipitation as a reasonable estimate for many soils. Because of the permeable Site soils and limited observable runoff at the Site, runoff was assumed to range from 0 in/yr (most conservative assumption) to 10 percent (reasonable upper-bound value) of the maximum precipitation value (10 percent of 50 in/yr = 5.0 in/yr).

Groundwater flux in the aquifer was calculated using Darcy's Law of the form:

$$Q_{gw} = (K * i * A_{aquifer}) * (\text{foot}/30.48\ \text{cm}) * (60\ \text{sec/min.}) * (7.48\ \text{gal/ft}^3)$$

where

Q_{gw} = flux of groundwater in gpm within the upper 10 feet of aquifer;
K = aquifer hydraulic conductivity in cm/sec;
i = hydraulic gradient in ft/ft;
$A_{aquifer}$ = aquifer vertical cross sectional area in ft^2 normal to groundwater flow; and

The last three terms on the right side of the equation are units conversion factors as indicated.

For the dilution factor to be applicable across the Site, probability distributions for hydraulic parameters were developed to represent both the Water Table Aquifer and unconfined Sea Level Aquifer at the Site.

- Hydraulic conductivity (K) was assigned a lognormal distribution with geometric mean of 5×10^{-2} cm/sec and a standard deviation of 25 percent of the mean. The mean value provides a reasonable conservative estimate for representing both Site aquifers based on available data (Hart Crowser, 1994). Because the aquifer dilution factor will be most sensitive to uncertainty in K, a standard deviation of 25 percent of the mean value was selected to provide a relatively constrained, thus useful, range of groundwater fluxes while encompassing the reasonable range of expected values for K in both

Site aquifers (5×10^{-3} to 5×10^{-1} cm/sec; refer to page A-6 in Attachment A [values are in natural logs]).

- Hydraulic gradient (i) was assigned a triangular distribution with minimum, most likely, and maximum values of 0.005, 0.028 (midpoint of range), and 0.05 ft/ft, respectively. The range of gradient values encompasses values measured in both Site aquifers (Hart Crowser, 1994).

- Aquifer cross sectional area was set at 10 ft^2, which is a one-foot width of aquifer by the 10-foot thickness of aquifer considered in this evaluation.

This probabilistic evaluation indicates that there is a 95 percent probability that the aquifer dilution factor (representing a minimum DAF for all constituents at the Site) is at least 2,400 (5th percentile value; refer to the dilution factor forecast statistics on page A-4 of Attachment A).

Soil Cleanup Level Determination Results

The results of the Monte Carlo simulation run with the aforementioned input assumptions indicates there is a 95 percent probability that a DNT soil concentration of 3 mg/kg is protective of Site groundwater under a drinking water scenario. The mean value in the DNT soil cleanup level distribution was 59 mg/kg and the most likely value (mode) was 20 mg/kg. Attachment A provides supporting information for the soil cleanup level determination, including forecasts with statistical output (pages A-1 through A-4) and assumptions (pages A-5 and A-6).

Conclusion

There is a high probability that a DNT soil cleanup level of 3 mg/kg will be protective of Site groundwater assuming a hypothetical drinking water exposure. The 3 mg/kg cleanup level was determined from a probabilistic evaluation which incorporated Site-specific data and their inherent uncertainty, while maintaining a high level of conservatism (e.g., not considering any of the dilution or attenuation processes occurring in the thick vadose zone at the Site). Because Site groundwater will not be used for drinking water supply under future use of the Site, higher DNT concentrations than 3 mg/kg in soil would be protective of the highest beneficial use of Site groundwater, which is discharge to surface water.

Re: Mercury Cleanup Levels Summary and Mercury/Lead Leaching Study

Dear Vern, Linda, and Jack:

This letter transmits the Department of Ecology's (Ecology) comments on the above reports dated July 19, 1993. The Ecology team (Dan Alexanian, Kelly Susewind, and myself) reviewed them and our approval/comments follow.

MERCURY CLEANUP LEVELS SUMMARY:

The Mercury Cleanup Levels Summary report is hereby accepted and approved. The Ecology team agrees with the approaches taken to establish site specific cleanup levels for mercury in soil. Based upon the work conducted by Hart Crowser, the soil cleanup level for mercury is 24.0 mg/kg (equivalent to parts per million (ppm)). That concentration of mercury, which is the Model Toxics Control Act Method "B" soil cleanup level, is protective of human health and the environment, including ground water and surface water. It should be noted that 24 mg/kg is the individual cleanup level for mercury, which may be adjusted downward depending on cumulative site risks associated with multiple hazardous substances or exposure pathways.

We do have comments on a couple statements made in the summary report. The summary report states, "...mercury concentration below 24 mg/kg in site soils will not leach to ground water..." and "...ground water and surface water have not and will not be impacted." These statements are overly definitive in relation to reality. More appropriate would have been statements such as the following, "...mercury concentrations below 24 mg/kg in site soils will not leach to ground water at harmful levels..." and "...ground water and surface water have not and will not be adversely impacted." Over time, be it geologic time, the mercury will eventually leach to ground water or surface water.

P 4, p 4: Flow rate varied between columns due to variations in dry soil density (compactness), and therefore "K".

Page 5, Table 3: Correct the location of the comma in the second column, third row from the top; 8,190 instead of 81,90.

P 6, p 2: The statement that the metals concentration in the leachate was proportional to the initial soil concentration is "a little strong." A preferable statement would be: metals concentration in the leachate increased with increasing initial soil concentrations.

P 6, p 3: "COL-3 ran for approximately twice as long as COL-1 and nearly ~~six~~ 5 times as long as COL-5." In that same paragraph, it refers to other columns with similar soil concentrations. Were other samples with similar concentrations tested? If not, it would be preferable to say "K_d was greater, indicating less leaching" or " K_d was same order of magnitude indicating similar leaching" or some other statement to indicate that the increased contact time did not adversely affect the results.

P 7, Table 5: The table needs to be modified to include another column showing averages. In our connotation, partition coefficient implies some sort of equilibrium, which is better represented by an average. The averages would be: column #1 is 32,000 L/kg, column #2 is 61,000 L/kg, and column #3 is 41,000 L/kg.

P 7, p 1: In that paragraph, please include the TCLP value for lead.

P 8, p 1: What is the "bonding/binding energy values from leaching solution thermodynamics" that is mentioned in that paragraph?

P 8, p 2: "Soil samples were leached using a 1:20 solid to liquid ratio." Is that ratio based upon weight? If by weight, the column tests used an average of 10.98 pounds (4.99 kilograms (kgs)) of soil and 10.28 kgs of water, therefore approximately a 1:2 ratio. Since all column tests reached or approached the detection limit of 0.2 ug/L, it is not too surprising that diluting the leachate ten fold in the ELP tests resulted in mostly non-detects, even with the increased contact. A brief comparison of the solid to liquid ratio for both tests would seem appropriate for the report.

P 10, Table 7: Is sample #ELP-IS-1 a TCLP test sample rather than an extraction leaching procedure sample? It is footnoted in Table 6 that #ELP-IS-1 is a TCLP sample. In general, the Tables need to be "cleaned up" to clearly identify or separate ELP results from TCLP results.

P 10, p 1: The first sentence states that the ELP data ranged from 16,000 to 36,000 L/mg for mercury. It is difficult to call that a "range," especially since those are only two data points and they are duplicate tests. Also, "This is also consistent with observed results from the column testing, indicating that both mercury and lead are preferentially adsorbed to site soils." Please explain how the underlined part of that sentence relates to the rest of that paragraph.

P 10, p 3: It states that a ratio of average leachate concentrations to initial concentrations was used. On page 9, it states soil:water partition coefficients were calculated from leachate and final soil concentrations. Which is it? Also, how did you calculate the lead ELP value of 2.6×10^{-5}?

P 11, p 1: We calculated that column test contact times ranged from 2 to 6 hours, based on pore volumes. How did you calculate contact times to get a range from 4.5 to 22 hours?

Because of the importance of these two reports, we want to ensure that they are as accurate and error-free as possible. If you have any questions or would like to arrange a meeting to discuss our comments and your responses on the two reports, please give me a telephone call at (206) 586-0364.

Sincerely,

Mike Blum

Admittedly, the mercury concentrations would be extremely low and the impact would probably be imperceptible, though the mercury will leach.

Also, in one of the footnotes, it states, "If mercury were leachable to groundwater it would have shown up in the groundwater sampling data since mercury sources have existed at the Site since the early 1900s." Mercury may have been used at the DuPont Works since the early 1900s, but when it was first released (spilled/discharged) into the environment and exposed to leaching and/or gravity is unknown.

MERCURY/LEAD LEACHING STUDY:

The Mercury/Lead Leaching Study report, as explained to me by Marian Wineman, is to be "viewed" as a reference document. Contained within that report is the backup information used or quoted in the Mercury Cleanup Levels Summary as well as information on lead leaching studies conducted at the same time as the mercury work. Currently, the lead leaching study results are not being used for purposes like the mercury data is. The Ecology team kept the above in mind while reviewing the report. Our detailed comments are as follows:

Page (P) 2, paragraph (p) 3: The text says the permeameter can accommodate 8-inch diameter samples up to 18 inches long. The schematic (Figure A-1) says a sample length of up to 12 inches. Which is it?

P 3, p 2: A hydraulic conductivity (K) of 3 x 10^{-5} cm/sec puts the recompacted sample in the silt range or the bottom of the silty sand range. In the Mercury Cleanup Levels Summary report (page V-2), it states that a K of 10^{-3} is at the lower end of the range of K estimates. It seems that the test material has an artificially low permeability. What potential effect (under estimated leachability? over estimated leachability?) does this decreased hydraulic conductivity have on the results? Does the over-compacted (lower permeability) sample increase contact times? Does it create preferential flow paths thereby decreasing contact time? A different effect? A couple other related issues (possible discrepancies or errors) were noted in the document.

> In that paragraph and Attachment B, it refers to COL-IS-5. Figure B-2 identifies the sample as COL-IS-5. On Table C-1, it refers to sample COL-IS-3 (with the same hydraulic conductivity as COL-IS-5) . Are the samples identified correctly or are they all really COL-IS-5?
>
> On Table C-1, shouldn't the ratio between before and after results be the same for "water content" and "saturation"?
>
> Is the hydraulic conductivity of sample COL-IS-5 actually 3 X 10^{-5}. That seems low for a sample containing 85% gravel and sands and only 16% silts and clays? It would be helpful to see the raw data sheets for computing hydraulic conductivity. Were hydraulic conductivities calculated for the other samples?

P 4, p 3: It states that the actual conditions for each column are summarized in Table 2. Table 2 only has a permeability number for Column #3 and none for columns 1 and 5. Are those permeabilities available?

P 4, Table 2: Columns 1 and 5 have the same dimensions but differ in weight by greater than 8%, therefore the density should also differ by 8%. Shouldn't the density for column 5 be 98 lb/ft^3 instead of 105? [18.48 / 19.99 (106) = 98 lb/ft^3.]

Also, on Table 2: The dry density for column 3 should be 117 rather than 116 lb/ft^3.

Re: Hot Spot Interim Action Report

Dear Jim and Ron:

The Ecology Team has reviewed the report entitled Hot Spot Interim Action Report dated October 4, 2000 and we have the following comments. I apologize for my delay in getting your our comments, as Dan Alexanian provided me with his comments a while ago.

1. Page 1, Section 1.1, Third paragraph: The Method C industrial soil cleanup level for trinitrotoluene (TNT) is identified in the report as 33 mg/kg. That level is the Method B concentration based on direct contact as a carcinogen. The Method C industrial cleanup levels are as follows:
Direct contact as a carcinogen - 4,380 mg/kg
Direct contact as a non-carcinogen - 1,750 mg/kg
Protective of groundwater as a carcinogen (100x the groundwater standard) - 2.92 mg/kg
Protective of groundwater as a non-carcinogen (100x the groundwater value)- 1.75 mg/kg
Based on protection of groundwater, the cleanup level would be 1.75 mg/kg, not 33 mg/kg. If you have some site-specific data on TNT and the leachability, that cleanup level might increase or decrease. It does look however, based on the existing sampling data, that TNT is not an issue anymore in the industrial area located north of Sequalitchew Creek. Prior sampling revealed higher TNT concentrations in Area 10 north of the creek.

2. Page 2, 2nd paragraph (and other locations in the report): "Sample 26-B-503-S-1 is located in a future Placement Area and was not removed because it will be covered with more than 15 feet of fill." The Ecology Team has some philosophical concerns about burying high levels of hazardous substances (25,000 mg/kg lead, for example), even when it is buried 15 feet or more and does not pose a threat to ground water. We should discuss this more in the near future. While it does comply with the Model Toxics Control Act regulations, it seems that if the material is easily accessible, it should be dealt with rather than just covering it over. If you continue with your proposal, you need to ensure that a minimum of 15 feet of fill is placed over those locations with "higher" contaminant concentration.

3. Page 17, Section A3: "In selected cases where the impacted soils are greater than 1.5 feet deep, the initial excavation was 10 feet by 10 feet." Why was 10 by 10 chosen rather than 50 by 50?

4. Pages 21 and 22, Section B7, the bullets: Please explain the statement "...therefore, no data were qualified." I appears from the various statements that there were problems in the lab with lead matrix spike recovery or control limits, but "no data were qualified". Only 2 of 17 bullets identified data that were qualified, though it appears that all the matrix spikes/blank spikes had problems.

5. General comment: It is hard to figure out how to compare original samples with post-excavation confirmational samples.

If you have any questions regarding the above comments, please give me a telephone call at (360) 407-6262.

Sincerely,

Mike Blum

C.6 TPH Soil Cleanup Level Protective of Groundwater

C.6.1 Review of TPH Soil Cleanup Level Protective of Groundwater

**REVIEW OF TPH SOIL CLEANUP LEVEL
PROTECTIVE OF GROUNDWATER
FORMER DUPONT WORKS SITE
DUPONT, WASHINGTON
FEBRUARY 12, 1996**

In recent discussions regarding residual Bunker C-derived TPH concentrations and backfilling of the Area 8 pipeline excavation (January 18, 1996, meeting), Ecology stated that they perceived inconsistencies in the TPH/PAH Cleanup Level Summary regarding a TPH concentration protective of Site groundwater (7,600 mg/kg vs. 11,000 mg/kg).

Response

There is evidence to support a Bunker C-derived TPH soil concentration of 30,000 mg/kg as protective of Site groundwater. The evidence is summarized below.

- Because the risk posed by Bunker C-derived TPH at the Site is associated with its cPAH content, a groundwater protection soil cleanup level for Bunker C-derived TPH was derived based on cPAH content in the TPH/PAH Cleanup Level Summary. In Appendix VI of that document, a Bunker C-derived TPH concentration of 7,600 mg/kg was determined by calculating a cPAH concentration protective of groundwater and back-calculating the corresponding TPH concentration from the TPH/cPAH regression (with 95% confidence; Appendix V of the TPH/PAH Cleanup Level Summary). A cPAH concentration of 12 mg/kg was initially calculated as protective of groundwater using the most stringent MTCA cPAH drinking water screening level (0.000012 mg/L), a conservative literature-derived value for cPAH partition coefficient (9,600 L/kg), and a conservative default dilution/attenuation factor (DAF) of 100.

  Applying the Site-specific DAF of 2,100 (refer to DNT Soil Cleanup Level Determination; October 1995) rather than a default DAF of 100 indicates that a cPAH concentration of 240 mg/kg is protective of Site groundwater. This corresponds to a Bunker C-derived TPH concentration above 30,000 mg/kg (as protective of Site groundwater). This value is consistent with preliminary findings from the Total Petroleum Hydrocarbon Criteria Working Group (TPHCWG). In the January 17, 1996, meeting of Ecology's Risk Assessment Forum TPH subcommittee, the TPHCWG presented example risk-based

groundwater protection cleanup goals of 35,000 mg/kg for motor oil, and higher (soil saturation [e.g., 25 percent TPH]) for weathered motor oil which is more representative of Bunker C-derived TPH at the Site.

- Leachable TPH was not detected in TCLP testing of Site soil samples with Bunker C-derived TPH concentrations up to 11,000 mg/kg. Leachable TPH was detected (16 mg/L) in a sample of Site soil with 19,000 mg/kg TPH, as reported in Appendix VI of the TPH/PAH Cleanup Level Summary and the Area 8 Interim Status Memorandum. Applying the Site-specific DAF of 2,100 to this leachate concentration produces a resultant estimated groundwater concentration of only 0.008 mg/L, well below the MTCA groundwater screening level of 1 mg/L. Alternatively, a Bunker C-derived TPH groundwater protection soil cleanup level which represents a soil saturated with Bunker C-derived TPH is determined from these data by multiplying a TPH desorption coefficient (K_d) of 1,200 L/kg (19,000 mg/kg ÷ 16 mg/L) by the DAF of 2,100 (MTCA groundwater screening level is 1 mg/L). As stated above, the TPHCWG's preliminary findings likewise indicate that soils fully saturated with high molecular weight hydrocarbons (like Bunker C) pose no risk to groundwater.

- After decades of rainwater leaching of residual TPH in Site soils, detection of TPH and cPAHs has not been confirmed in Site groundwater.

Conclusion

Site-specific data, corroborated by the findings of the TPHCWG, indicate that Bunker C-derived TPH concentrations of 30,000 mg/kg in Site soils will not adversely impact Site groundwater. This value is higher than the previous determination because it includes a more realistic assessment of the substantial natural dilution/attenuation occurring at the Site (Site-specific DAF of 2,100 compared to a default of 100).

ECOLOGY MEETING
February 15, 1996

Attendees: Mike Blum, Dan Alexanian, Kelly Susewind, Vern Moore, Jeff King, Steve Germiat, Marian Wineman, Geneva Smith

Paraffin Investigation

The Weyerhaeuser/DuPont team reported they had conducted additional sampling in Areas 6, 12, and 38 in order to verify the presence of paraffin wax-derived TPH. A Paraffin Investigation report was presented to Ecology which outlined details of the soil sampling, analysis results, and exploration location maps.

Area 6, Crystallizer Drum Area

Oil was detected in the two surface soil samples that were taken. The results did not confirm paraffin as the source of TPH.

Area 12, Works Magazine Landfill

Fourteen confirmation soil samples were collected from RI and pre-RI sampling locations where elevated TPH and/or oil and grease were detected. It was determined that paraffin associated with waxed cardboard boxes most likely accounted for the majority of TPH detected during the RI sampling. Low concentrations of diesel were detected in three of the samples.

Mike Blum of Ecology stated that the samples taken from Unit 12-2 did not necessarily confirm that all the TPH was paraffin-based. Additional sampling might provide extra support.

Marian Wineman of the Weyerhaeuser/DuPont team stated there were many variabilities in Area 12 and paraffin was very patchy throughout the area, which could result in patch hits. Three monitoring wells in the location have not detected TPH. She also stated that the chromatogram for paraffin was nearly identical to the chromatograms from Area 12.

Area 38, Carton Production Area and Drywell

TPH concentrations above the MTCA screening level were detected in three RI samples in Area 38. Interim source removal was conducted in October 1995 and verification samples were taken. Paraffin was not detected in any of the samples. Oil and diesel were detected.

Path Forward:

Ecology will review Paraffin Report and decide whether or not additional sampling will be needed.

Review of TPH Soil Cleanup Level Protective of Groundwater

Discussion on residual Bunker C-derived TPH concentrations and the backfilling of Area 8 pipeline excavation. The Weyerhaeuser/DuPont team responded to Ecology questions regarding inconsistencies in the TPH/PAH Cleanup Level Summary regarding a TPH concentration protective of Site groundwater. Steve Germiat of the Weyerhaeuser/DuPont team stated that site-specific data indicated that Bunker C-derived TPH concentrations of 30,000 mg/kg in Site soils would not adversely impact the groundwater.

Mike Blum of Ecology stated that Ecology did not necessarily agree with the 30,000 mg/kg number. He stated that in general, the TPH values were probably protective of groundwater using the DAF. There is concern about the PAH's since chrysene is showing up in some of the monitoring wells.

Dan Alexanian of Ecology stated that the proposed monitoring well would be down-gradient from Area 8 and could be used to monitor PAHs, as well as DNT. Mike Blum gave approval for Area 8 to be backfilled, but stated the PAH in groundwater still needed to be dealt with in determining TPH soil cleanup levels protective of groundwater. Dan Alexanian agreed with this on the condition that if necessary (after the PAC decision), the Weyerhaeuser/DuPont team would come back in and clean up locations which exceed the PAC's number.

Path Forward:

- *Area 8 to be backfilled.*
- *Ecology to review TPH/cPAH data with regards to establishing Site TPH soil cleanup levels.*
- *Weyerhaeuser/DuPont team to tabulate all sample concentrations exceeding MTCA screening levels at depths below 15 feet.*

Other Issues

Discussion on arsenic background number of 32 ppm. Ecology agrees with the work that has been done and with the 32 ppm number.

Path Forward:

- *Parcel 2 draft RI package to Ecology. (22 March 1996)*
- *W/D will initiate first draft of Parcel 2 CAP.*

Schedule for remainder of the Site was discussed. It could take more than two years for the PAC to come up with recommendations, for Ecology to put together some policies, and get changes made in the regulations. Mike Blum stated Ecology would like to begin making some decisions for this site.

Vern Moore stated that the golf course alternate plan would be submitted to the City of DuPont around the middle of March. It is grandfathered under the City's 1985 Comprehensive Plan. The Weyerhaeuser/DuPont team would like to see the Department of Ecology sponsor the EIS, lending more efficiency and speed to the

project. The Weyerhaeuser/DuPont team gave Ecology a 2001 to 2002 estimate for completion of the cleanup.

Ecology will confirm with the Weyerhaeuser/DuPont team a date for a general meeting with everyone invited. (This has been confirmed for 3/19/96 8:30 am - 12 noon at DuPont field office).

C.6.2 TPH/PAH Cleanup Level Summary

tile: Final Draft

DRAFT

TPH/PAH CLEANUP LEVEL SUMMARY

INTRODUCTION

The appropriate soil cleanup levels for total carcinogenic polycyclic aromatic hydrocarbons (cPAH) in each land use area at the Former DuPont Works Site (the "Site") are as follows:[1]

Land Use	cPAH
Residential	1 to 10 mg/kg
Open Space	5 to 50 mg/kg
Golf Course	20 to 220 mg/kg
Industrial	30 to 300 mg/kg

The appropriate soil cleanup levels for Bunker C fuel-derived total petroleum hydrocarbons (TPH) are 3,100 to 27,000 mg/kg.

TPH/cPAH cleanup levels for groundwater are not established because groundwater and surface water at the Site are in compliance with MTCA screening levels.

---

[1] Soil cleanup levels apply to soils from 0 to 15 feet in depth. WAC 173-340-740(6)(c).

TPH AND cPAH DETECTED AT THE SITE

TPH and/or cPAH concentrations above MTCA screening levels were detected at 15 areas of the Site. Interim source removal actions have been conducted in eight of those areas. TPH and/or cPAH concentrations above MTCA screening levels remain only in two of these interim source removal areas: Area 5 (mixed petroleum products) and Area 8 (Bunker C fuel-derived TPH). An interim source removal action in Area 24 will be conducted in 1994, and verification data will determine whether TPH/cPAH concentrations above MTCA screening levels remain.

Six additional (non-source removal) areas contain TPH and/or cPAH concentrations above MTCA screening levels. Areas 7 and 16 contain Bunker C fuel-derived TPH. Area 26 contains mixed petroleum products. Areas 6, 12 and 38 contain non-hazardous paraffin-derived TPH. No toxic fraction is associated with paraffin-derived TPH, and no cPAHs were detected in any of these three areas. Accordingly, no further action based on petroleum constituent concentrations is proposed for the three areas with nonhazardous paraffin-derived petroleum constituents.

Appendix I summarizes TPH and cPAH concentrations in soil in each area of the Site that has had concentrations above MTCA screening levels, and provides information regarding the source of petroleum constituents for each area. Appendix II describes

the TPH/cPAH composition of the Bunker C fuels present at the Site.

CLEANUP LEVELS FOR TPH/cPAH IN SOILS

1. Soil cleanup levels for cPAH. The MTCA Cleanup Regulation requires establishment of cleanup levels based on estimates of the reasonable exposures expected to occur under both current and future site use conditions. WAC 173-340-740(1)(a).

The City of Dupont 1985 Comprehensive Land Use Plan for the area South of Sequalitchew Creek will result in that area being used exclusively for residential, recreational and commercial uses. Recreational uses may include an 18-hole golf course (that will cover a significant portion of the area South of Sequalitchew Creek) and open space, or "green belts," along the Creek, in the kettle areas, and around Old Fort Lake. Commercial uses will cover the remaining areas that are not specifically developed as residential neighborhoods. The cPAH cleanup levels were developed for each planned residential and recreational land use area.[2] Cleanup levels were also developed for the industrial areas of the Site that are located North of Sequalitchew Creek.

---

[2] Residential cleanup levels will apply in the commercial areas because many commercial areas will have mixed commercial and residential uses.

The cPAH cleanup levels for residential land use are derived using exposure assumptions that are representative of chronic exposures with children as the sensitive receptor population. (Note, however, that cPAH has not been detected above MTCA screening levels in areas currently planned for residential development.)

The cPAH cleanup levels for open space land use are derived using reasonable exposure assumptions representative of children in a recreational setting. Soils in the areas of the Site planned for open space uses will not be disturbed by activities typical in residential areas such as gardening and landscaping. Landscaping and vegetative ground cover will further reduce the availability of surface soils for direct contact. However, incidental soil ingestion by children has been considered in setting the cleanup levels for cPAH in open space areas.

The cPAH cleanup levels for golf course land use are derived using exposure assumptions appropriate to golf course maintenance workers. Golfers (and other persons with access to the golf course) would not be potentially exposed to residual constituents in native soils because the entire golf course area will be covered by 1 to 2 feet of topsoil and golf course turf grasses.[3]

---

[3] Some golf course areas may also be covered by concrete or asphalt roads, parking lots, golf cart paths, and by structures such as a club house, maintenance and storage buildings, etc.

Thus, the only potentially exposed persons would be golf course workers (adults) who occasionally may come into contact with native soils during maintenance of the golf course. Exposure in these circumstances would be infrequent and of limited duration.

The cPAH cleanup levels for industrial land use are derived using exposure assumptions appropriate to protect an adult worker that might have daily contact with Site soils.

In accordance with WAC 173-340-708(3)(c), documentation for the use of Site-specific exposure scenarios is provided in Appendix III.

2. Soil cleanup levels for TPH. The risk presented by the Bunker C fuel constituents detected at the Site is attributable to its cPAH components. See Appendix IV. Accordingly, correlation analyses were performed to assess the statistical relationship between cPAH and TPH concentrations, and to establish TPH cleanup levels for Bunker C fuel-derived TPH detected in Areas 7, 8 and 16.[4] See WAC 173-340-702(6) (Ecology "**shall** consider new scientific information when establishing cleanup levels for individual sites").

---

[4] No TPH cleanup level is established for Areas 5 and 26 that have mixed petroleum products because cleanup of metals contamination in those areas will also cleanup soils with petroleum constituents. Verification testing will be done in those areas to confirm that no TPH concentrations remain above MTCA screening levels.

The results indicate that cleanup levels of 3,100 to 27,000 mg/kg for Bunker C fuel-derived TPH will correspond to the residential cleanup goal of 1 to 10 mg/kg for cPAH. Appendix V explains the analysis used to establish TPH cleanup levels. See also, WAC 173-340-740(3)(ii)(B).

TPH/cPAH CONCENTRATIONS IN SITE GROUNDWATER AND SURFACE WATER DO NOT POSE A RISK TO HUMAN HEALTH

TPH/cPAH cleanup levels are not established for groundwater because TPH/cPAH concentrations are not present above MTCA screening levels in groundwater or surface water at the Site. Appendix VI sets forth TPH/cPAH concentrations detected in Site groundwater and surface water during RI sampling.

- TPH was not detected in any groundwater or surface water sample collected during the four rounds of RI water sampling;
- no groundwater samples had detections of any noncarcinogenic PAH above the MTCA drinking water screening levels;
- no groundwater sample had detections of total cPAH above the MTCA screening level, except a single unconfirmed detection in one well that is not considered representative of groundwater quality;

- no TPH or noncarcinogenic PAHs were detected above MTCA screening levels in any surface water samples; and
- no cPAH were detected in any surface water sample, except a single detection which was the result of elevated sample turbidity and which is not representative of surface water quality at the Site.

TPH/PAH CONCENTRATIONS IN SITE SOILS, GROUNDWATER AND SURFACE WATER ARE PROTECTIVE OF ECOLOGICAL RECEPTORS

A quantitative ecological risk assessment was performed to estimate the potential risk posed by TPH/cPAH in soils at the Site. See Appendix VII.

The results of the ecological risk assessment indicate that cPAH concentrations in soil below 30 mg/kg are protective of ecological receptors at the Site. No cPAH-related ecological risks would be present in the residential areas of the Site at the TPH cleanup levels ranging from 1 to 10 mg/kg. cPAH concentrations in the open space areas of the Site are less than 30 mg/kg. Finally, there will be no risk to ecological receptors in the golf course area because the topsoil cover, golf course turf grasses and golf course maintenance will minimize small mammal exposure to the underlying subsurface soils.

The risk to ecological receptors from exposure to Bunker C fuel-related TPH is attributable to its cPAH components. The cPAH concentration of 30 mg/kg determined to be protective of ecological resources corresponds to a TPH soil concentration of 76,000 mg/kg. Thus, at the cleanup levels established for TPH (3,100 to 27,000 mg/kg), Site soils will not present a risk to ecological receptors.

CONCLUSION

The following soil cleanup levels for cPAH/TPH are established based on land use:

1. For residential land use, the appropriate cPAH cleanup level is 1 to 10 mg/kg;

2. For open space land use, the appropriate cPAH cleanup level is 5 to 50 mg/kg;

3. For golf course land use, the appropriate cPAH cleanup level is 20 to 220 mg/kg;

4. For industrial land use, the appropriate cPAH cleanup level is 30 to 300 mg/kg.

5. For soils that contain Bunker C fuel-derived TPH, the appropriate cleanup level is 3,100 to 27,000 mg/kg.

The cPAH/PAH cleanup levels set forth above are protective of ecological receptors. No groundwater risk is present at the Site because TPH/cPAH concentrations in groundwater are well below MTCA screening levels.

APPENDIX I
SUMMARY OF TPH/PAH IN SOILS

Total petroleum hydrocarbons (TPH) have been detected in soil samples collected from 15 areas of the Site. Based on historical records and chemical fingerprinting (chromatogram) analyses, the primary source of the TPH on the Site is Bunker C fuel. However, a few Site areas have TPH detections associated with sources other than Bunker C fuel, including mixed petroleum types (gasoline, kerosene, and diesel formerly occurred in former UST locations) and paraffin.

Because MTCA allows for the evaluation of the toxic fraction of TPH (WAC 173-340-730[3][ii][B]), TPH-containing soils were also analyzed for polycyclic aromatic hydrocarbons (PAHs) and/or benzene, toluene, ethylbenzene, or xylenes (BTEX) depending on the petroleum type.

Of the 15 areas where TPH has been detected, interim source removal has been conducted in eight areas, and interim source removal is planned for a ninth area (Area 24, Main Powerhouse) in 1994. Ecology has reviewed verification sampling data for three of these areas and has determined that No Further Action (NFA) is needed in these areas.

Interim Source Removal Areas Approved by Ecology for No Further Action

- **Area 20—Underground Storage Tanks.** Four underground storage tanks which formerly contained kerosene, diesel, or gasoline, have been removed and the associated petroleum-containing soils overexcavated (Hart Crowser, 1991);

- **Area 38—Box Production Area Underground Storage Tank.** Diesel and/or Bunker C were identified in one underground storage tank, which has been removed, and the associated petroleum-containing soils overexcavated (Hart Crowser, 1993); and

- **Area 39—Laboratory Underground Storage Tank.** Gasoline was identified in one underground storage tank, which has been removed, and the associated petroleum-containing soils overexcavated (Hart Crowser, 1993).

These three areas, which have been approved by Ecology for NFA, will not be addressed further. Area 24, the Main Powerhouse, is scheduled for interim source removal during 1994.

The remaining eleven areas are addressed below according to the petroleum type identified in each area.

Bunker C-Derived TPH

Analysis of Bunker C-Derived TPH

Fourteen soil and product samples from the Area 8 pipeline were analyzed for fuel identification (EPA Method 8015 Modified) or volatile organic compounds (EPA Method 8240). Bunker C was identified in eight of these samples. No BTEX was detected in any of the samples where Bunker C was identified.

Based on these results, it was determined that BTEX was not representative of the toxic fraction of Bunker C-derived TPH (WAC 173-340-740[3][ii][B]).

Carcinogenic PAHs (cPAHs) were detected in each area with elevated concentrations of Bunker C-derived TPH. Non-carcinogenic PAHs were not detected at the Site above MTCA screening levels, and therefore will not be addressed further.

Areas where Bunker C occurs include Areas 7, 8, 16, and 24. The appropriate cleanup level for TPH in these areas was determined on the basis of a correlation evaluation of the TPH and corresponding total cPAH concentration (toxic fraction per WAC 173-340-740[3][ii][B]) and future land use, as described in Appendix V.

Additional discussion of Bunker C-derived TPH in Areas 7, 8, and 16 is provided below. Area 24 is not discussed because interim source removal is planned for later in 1994.

Interim Source Removal of Bunker C-Derived TPH in Area 8

The objective of the Area 8 interim source removal was to excavate soils containing total cPAH concentrations above 1 mg/kg to a depth of 15 feet (WAC 173-340-740[6][c]).

Post-removal TPH concentrations in the upper 15 feet of soil ranged from not detected (ND) to 200 mg/kg. Post-removal cPAH concentrations in samples in the upper 15 feet of soil were all below detection limits. Post-removal TPH concentrations of soil at depths greater than 15 feet ranged from not detected to 11,000 mg/kg. Post-removal total cPAH concentrations of soil at depths greater than 15 feet ranged from not detected to 4.4 mg/kg. Based on the total cPAH/TPH correlation and

considerations of TPH leachability, all targets associated with cPAH and groundwater protection have been achieved by the interim source removal. The cPAH/TPH correlation evaluation is discussed in Appendix V. TPH leachability is discussed in Appendix VI. Table I-1 summarizes TPH/cPAH concentrations in Area 8.

Table I-1 - TPH and cPAH Concentrations in Area 8 Following Interim Source Removal

Area	Range of Concentrations in mg/kg	Detection Frequency	Arithmetic Mean in mg/kg	95 Percent UCL in mg/kg
TPH				
8 (< 15 ft)	ND to 200	6/17	40	200
8 (all depths)	ND to 11,000	32/48	1,300	11,000
Total cPAH				
8 (< 15 ft)	ND	0/6	ND	ND
8 (all depths)	ND to 4.4	2/13	0.4	4.4

ND: Not detected. TPH detection limit of 21 mg/kg; cPAH detection limit of 0.06 mg/kg.

Bunker C-Derived TPH in Areas 7 and 16 (Non-Interim Source Removal Areas)

A surficial layer of Bunker C residue is present in portions of the bottoms of the Area 7 and Area 16 kettles (Hart Crowser, 1992a). Fuel identification analyses performed on samples of the residue from each of these areas confirm that weathered and unweathered Bunker C residue is present in each area, and the residues in each area are similar (refer to Appendix II). Table I-2 presents TPH and cPAH data for Areas 7 and 16.

Table I-2 - TPH and cPAH Concentrations in Areas 7 and 16 (Bunker C-Derived TPH)

Area[1]	Range of Concentrations in mg/kg	Detection Frequency	Arithmetic Mean in mg/kg	95 Percent UCL in mg/kg
TPH				
7	ND to 10,000	15/29	960	10,000
16	ND to 2,500	29/51	310	2,200
Total cPAH				
7	ND to 2.9	5/7	0.8	2.9
16	ND to 17.9	8/19	1.5	17.9

ND: Not detected. TPH detection limit of 21 mg/kg; cPAH detection limit of 0.06 mg/kg.

(1) Concentrations are summarized for samples above 15 feet because, where sampled, no detections of TPH or cPAH occurred below 15 feet in these areas with the exception of one sample with 28 ppm TPH in Area 16.

Mixed Petroleum-Derived TPH

Analysis of Mixed Petroleum-Derived TPH

BTEX was detected in soils formerly associated with USTs, which have been removed during interim source removal in Areas 20, 38, and 39. Ecology has determined that NFA is required in these areas (see above).

Areas found to contain mixed petroleum products are Areas 5, 19, 35, 26, 40, and one subunit of Area 12, Area 12-2. These areas are discussed below, with the exception of subunit Area 12-2 which is discussed in the ***Non-Hazardous Paraffin-Derived TPH*** section below.

Interim Source Removal Areas - Mixed Petroleum-Derived TPH

Area 5. Area 5 formerly contained debris deposited and partially buried on the western slope of the Area 16 kettle. The area has been used since at least the 1940s for disposal of non-burnable materials. Prior to debris removal activities in the area, the debris included a variety of containers including drums, demolition debris, and general refuse. The majority of the drums removed were apparently empty and non-hazardous. However,

85 drums contained mixed petroleum products (oil, tar, grease, and asphalt), which contributed to elevated TPH concentrations in this area.

Area 5 interim source removal was based on excavating soils with elevated concentrations of DNT, metals, TPH, and PAHs. Following the interim source removal, verification soil samples collected from the area contained TPH concentrations ranging from not detected to 1,900 mg/kg. Verification data for cPAHs indicated concentrations ranging from 0.3 to 2.4 mg/kg.

The mixed petroleum products detected in Area 5 are associated with concentrations of other constituents above MTCA screening levels, mainly lead and arsenic. Cleanup of soils for lead and arsenic will remove all TPH-containing soils above the MTCA screening level, therefore, it is unnecessary to establish cleanup levels for TPH in this area.

Area 19. Petroleum-containing soil from the area around the Oil House was excavated and removed. Verification soil sample results indicated concentrations in samples ranging from below detection limits to 29 mg/kg, well below the MTCA screening level. Therefore, TPH will not be addressed further in this area.

Area 35. Three drums containing a solidified tar-like substance were removed. Verification soil sample results indicated TPH concentrations were below detection limits. Therefore, TPH will not be addressed further in this area.

Area 40. Soils from a drywell at the Press House in Area 40, which previously contained TPH and PAH concentrations above screening levels, were excavated during interim source removal. Verification soil sample results indicated that concentrations of TPH were below detection limits. Therefore, TPH will not be addressed further in this area.

Table I-3 provides TPH and cPAH data for interim source removal Areas 5, 19, 35, and 40.

Table I-3 - TPH and cPAH Concentrations in Mixed Petroleum-Derived TPH Areas Following Interim Source Removal

Area[1]	Range of Concentrations in mg/kg	Detection Frequency	Arithmetic Mean in mg/kg	95 Percent UCL in mg/kg
TPH				
5	ND to 1,900	45/85	130	330
19	ND to 70	2/13	19	70
35	ND	0/3	ND	ND
40	ND	0/2	ND	ND
Total cPAH				
5	0.33 to 2.4	8/8	1.3	2.4
19	0.28	1/1	—	—

ND: Not detected. TPH detection limits of 20 to 50 mg/kg; cPAH detection limit of 0.06 mg/kg.

(1) Concentrations are summarized for samples above 15 feet because, where sampled, no detections of TPH or cPAH occurred below 15 feet in these areas.

Mixed Petroleum-Derived TPH in Area 26 (Non-Interim Source Removal Area)

Area 26 (Unit 26A) Kettle. Area 26 includes the facilities used for reconstruction of spent acids returning from the nitroglycerin production area. One of the two kettles (Unit 26A) located south of the recovery facilities reportedly received liquid discharge from several sources, including the vehicle maintenance and truck wash facility. TPH concentrations above the MTCA direct contact screening level were detected in surface soil samples collected from several locations on the northern portion of the kettle floor, and are a mixture of petroleum products derived from the vehicle maintenance facility (Table I-4). Fuel fingerprint analysis (EPA Method 8015 Modified) identified the substance as heavy oil. The results are distinctly different from Area 7 and Area 16 (kettles) fuel identification results, which indicated Bunker C. No Bunker C residue is evident in the Unit 26A kettle.

Soil samples, which contained TPH above MTCA screening levels, also contained concentrations of other constituents, mainly lead. Cleanup of

soils for lead will remove TPH-containing soils above the MTCA screening level, therefore, it is unnecessary to establish cleanup levels for TPH in this area.

Table I-4 - TPH and cPAH Concentrations in Area 26 (Mixed Petroleum-Derived TPH)

Area[1]	Range of concentrations in mg/kg	Detection Frequency	Arithmetic Mean in mg/kg	95 Percent UCL in mg/kg
TPH				
26	ND to 5,600	15/47	380	810
Total cPAH				
26	ND to 37.0	9/11	4.1	37.0

ND: Not detected. TPH detection limit of 21 mg/kg; cPAH detection limit of 0.06 mg/kg.

(1) Concentrations are summarized for samples above 15 feet because, where sampled, no detections of TPH or cPAH occurred below 15 feet in these areas.

Non-Hazardous Paraffin-Derived TPH

Analysis of Paraffin-Derived TPH

Paraffin wax is a white, semi-translucent, flammable, odorless solid (Clayton and Clayton, 1982). It is a mixture of solid, high molecular weight (C-30 to C-40 range) hydrocarbons, primarily alkanes derived from petroleum sources (Sax, 1987). Paraffin is insoluble in water and is soluble in organic solvents and oils (Sax, 1987). Paraffin wax is used for coating paper and food containers, medicinal agents, candles, sealant, and chewing gum base. Paraffin wax is biologically inert for the Site exposure routes (RTECS, 1994).

The TPH analysis (EPA Method 418.1) does not distinguish between paraffins and other petroleum-derived products; however, historical Site use and field observations conducted during the RI confirm that only waxes and paraffins are present in Areas 6, 12, and 38. Historical information indicates that paraffin was used as a protective coating on boxes and cartons used to pack and ship Site products. Paraffin-containing drums or paraffin-coated boxes were found in each of these three areas. In addition, no cPAHs were detected in any of these three areas. Since cPAHs were

not detected in soil samples collected from the three areas (Areas 6, 12, and 38) and there is no toxic fraction associated with the paraffin-derived TPH, the TPH will not be addressed further in these areas.

Area 6. Area 6 was used for disposal of defective 55-gallon ammonium nitrate drums used at the ammonium nitrate plant. A total of 1,600 drums were removed from this area during interim source removal. Except for seven drums, the drums were empty. The non-empty drums contained residual ammonia salts and paraffin, as identified by field screening analysis. Soil samples above the MTCA screening level were confined to surface samples (0 to 1 foot in depth). The soil TPH detections in this area are associated with residue from the paraffin-containing drums. No other potential TPH sources were identified in the historical records or field observations for this area.

Area 12. Wastes related to explosives packaging activities in the Works Magazine were buried in shallow excavations in several areas of the Works Magazine landfill. Waste materials buried include explosives packaging, auto shop wastes, empty ammonium nitrate drums, and residual monomethylamine nitrate (MMAN). Five of seven Area 12 landfill units contain elevated TPH concentrations. The highest concentrations of TPH were detected in samples from locations containing paraffin-coated cardboard, residual MMAN, and mixed solid waste. Mixed solid waste found in Area 12 consisted of various materials, including metal strapping, miscellaneous plastic bags, foam rubber, wood debris, cloth, and rubber hose. The TPH detections are associated with the paraffin coating on the cardboard packaging.

cPAHs were not detected in any of the 22 soil samples analyzed for Area 12. Of the landfill units with elevated TPH, autobody parts and waste oil were observed in only one (Unit 12-2) of the five units with elevated TPH concentrations during the excavation of test pits. All soil samples in this unit containing elevated TPH concentrations also contained residual MMAN concentrations above MTCA screening levels. Cleanup of soils for MMAN will remove TPH-containing soils above the MTCA screening level, therefore, it is unnecessary to establish cleanup levels for TPH in this unit of Area 12.

Area 38. Area 38 encompasses the buildings used for production and labeling of boxes and cartons used to package and ship products from the Site. Packaging materials were originally wooden boxes, which, over time, were replaced by paraffin-coated cardboard cartons. Both cardboard printing and paraffin coating activities occurred in this area. Water and/or solvents used to clean printing equipment in the box factory drained through a wooden trough from the building into a drywell located

approximately 15 feet south of the box factory. TPH concentrations above the MTCA screening level were detected in the three soil samples collected from the trough (two samples) and drywell (one sample). No cPAHs were detected in these samples although four of the ten samples had detection limits greater than 1 mg/kg due to sample matrix interference. Benzene and xylene, associated with historical use of solvents for cleaning printing equipment, were detected at concentrations well below MTCA screening levels in the surficial sample collected within the drywell. No BTEX were detected in deeper samples from the drywell.

A UST (containing diesel and/or Bunker C) was removed approximately 15 feet from the drywell in Area 38. All soils containing TPH above MTCA screening levels were removed in association with the UST removal (Hart Crowser, 1992b).

Residual paraffin was likely washed down the trough to the drywell from in the box factory, therefore the source of the TPH detected in Area 38 (limited to the trough and drywell) is most likely the paraffin. Because the analytical method for TPH (EPA Method 418.1) does not detect BTEX, and the detected TPH concentration (1,400 mg/kg) in the surficial sample from the drywell was substantially higher than the detected total BTEX concentration (1.9 mg/kg) in that sample, the TPH does not appear to be associated with the BTEX.

Regardless, all elevated TPH concentrations detected at the trough and drywell were limited to samples collected from 0 to 1.5 foot and were associated with concentrations of other constituents above MTCA screening levels, including arsenic, mercury, and lead. These other constituents were also detected at greater depths (2 to 4 feet) than TPH at these locations. Cleanup of soils for lead, arsenic, and mercury will remove all TPH-containing soils above the MTCA screening level, therefore, it is unnecessary to establish cleanup levels for TPH in this area.

Table I-5 provides data on Paraffin-Derived TPH concentrations in Areas 6, 12, and 38.

Table I-5 - TPH Data for Areas 6, 12, and 38 (Paraffin-Derived TPH)

Area[1]	Range of Concentrations in mg/kg	Detection Frequency	Arithmetic Mean in mg/kg	95 Percent UCL in mg/kg
TPH				
6	ND to 1,900	6/9	450	1,900
12	ND to 36,000	14/43	1,500	9,400
38	ND to 1,400	15/19	180	950

ND: Not detected. TPH detection limit of 20 mg/kg.
(1) Concentrations are summarized for samples above 15 feet because, where sampled, no detections of TPH or cPAH occurred below 15 feet in these areas.

Conclusions

TPH and cPAHs detected in several Site areas are associated with three different sources. The primary Site petroleum source, Bunker C, is confined to four areas (7, 8, 16, and 24) which have either undergone interim source removal or will be addressed subsequently. Mixed petroleum types were identified in five areas (5, 19, 26, 35, and 40) and one Area subunit (Unit 12-2). Interim source removal has been conducted in Areas 19, 35, and 40. Further action to address other constituents in Areas 5, 12-2, and 26 will concurrently address the remaining TPH concentrations above screening levels. Additionally, no further action, based on TPH concentrations, is proposed for the three areas with non-hazardous paraffin-derived TPH and no detected cPAHs (Areas 6, 12, and 38).

APPENDIX II
BUNKER C TPH/PAH COMPOSITION

As summarized in Appendix I, TPH on the Site has been detected in several forms. The composition of TPH determines its mobility and its potential to impact groundwater, as well as its toxicity. Bunker C fuel, associated primarily with the powerhouse and pipeline, is the predominant form of TPH on site (Appendix I). Bunker C and paraffin tend to adsorb tightly to soils and are not mobile. In support of this, TPH has not been detected in site groundwater (Appendix VI).

TPH composition also determines toxicity (Appendix IV). The toxicity of Bunker C, composed of heavier hydrocarbons, is associated primarily with cPAHs. No toxic fraction has been identified for paraffin. Because Bunker C is the predominant form of TPH found on site, its composition and how its composition effects mobility and toxicity is discussed in this Appendix.

Bunker C - Derived TPH

In general, Bunker C fuels, or heavy fuel oils, consist of a wide variety of formulations. The primary components of Bunker fuels are naphthenes, asphaltenes, saturated hydrocarbons, and aromatic hydrocarbons. Naphthenes, or cycloparaffins, are saturated cycloalkanes consisting primarily of 3 carbon-ring (cyclopropane), 4 carbon-ring (cyclobutane), 5 carbon-ring (cyclopentane), and 6 carbon-ring (cyclohexane) compounds. These ring structures may have a variety of saturated side chains. Asphaltenes are the heavier petroleum component of Bunker C and consist of primarily saturated longer chain compounds. Saturated hydrocarbons are represented by the long chain alkane compounds. Finally, the aromatics are primarily composed of PAHs. cPAHs have been determined to be the toxic fraction of Bunker C fuels.

Different formulations of Bunker C fuel oil are composed of varying concentrations of each of these components. A study by Bobra and Callaghan (1990) demonstrated the degree of variation in Bunker C compositions:

Component	% Content
Naphthenes	45
Asphaltenes	6 to 14
Saturates	15 to 24
Aromatics	25 to 55

Chromatograms of Bunker C product show that as much as 70 percent of its composition is hydrocarbons in the C-20 or higher range (refer to Figures II-1 and II-2).

Bunker C has been found in two forms on the Site. A viscous product is present in two areas (the Powerhouse - Area 24 and the Bunker C pipeline - Area 8), while a hardened tar-like residue was found at the bottom of Area 7 and Area 16 kettles.

Soils in Area 8, which contain elevated concentrations of Bunker C, have been removed to achieve the cPAH screening level of 1.0 mg/kg throughout the upper 15 feet of soil. Area 24 is scheduled for further action in 1994.

Kettle area soils are typically visibly stained and may have a hardened residue resulting from weathering of residual Bunker C. GC-FID fuel identification scans were performed on samples of the viscous and tar-like materials collected from these areas. Analysis of the chromatograms for these samples indicate that the viscous product from Areas 8 and 24 is unweathered Bunker C, and the hardened product from Areas 7 and 16 is weathered Bunker C. Weathered products typically do not show lighter-end hydrocarbons that show up in the unweathered samples. Lighter-end hydrocarbons have a greater tendency than heavier compounds to volatilize, degrade, or mobilize when exposed to the environment. Chromatograms for one weathered sample (16-SS-502) and one unweathered sample (16-SS-503) are included on Figures II-1 and II-2, respectively.

The limited mobility of weathered Bunker C was confirmed by subsurface explorations in Areas 7 and 16. TPH detections in explorations within the kettles correspond to a distribution of a thin layer (typically 1 to 6 inches) of hydrocarbons across the bottom of the kettles. Data from Area 7 subsurface explorations indicate that elevated TPH concentrations are vertically bounded to the upper 3 feet of material. Elevated TPH concentrations in Area 16 are vertically bounded to the upper 1 foot of material.

Bunker C product from the pipeline (Area 8) exhibits greater mobility than the weathered product. The practice of heating the fuel prior to pumping it through the pipeline may have increased mobility of Bunker C from the pipeline. Leakage from pipeline joints over time, pressurizing the pipe to improve transport, and the large volumes of product transported, all contributed to the mobilization of Bunker C in this area. Bunker C product from the pipeline was detected up to 35 feet below the ground surface. However, the pipeline has not been used since the mid-1960s. Interim

source removal in Area 8 has further controlled the TPH source in this area and also achieved cPAH screening levels. Based on soil leachability testing (TCLP) performed on soil samples collected from Area 8 (Appendix VI), residual TPH present in this area at the conclusion of interim source removal is not a possible TPH source to groundwater.

Bunker C-Derived cPAH

Locations where TPH was detected were evaluated for PAH composition. Soil samples from Area 8 analyzed for PAHs indicate the presence of 12 of 16 PAHs analyzed. Characterization of PAHs was performed on 52 soil samples from Area 8 with cPAHs detected in 31 of the 52 samples.

Site-wide soil testing demonstrated that the seven cPAHs were present in different areas. Chrysene is the predominant cPAH appearing in 40 out of 121 soil samples tested for PAHs, with a maximum concentration of 14 mg/kg. However, chrysene is the least potent cPAH, exhibiting a relative potency of 0.1 percent that of benzo(a)pyrene (BAP; EPA, 1993) (Appendix IV). Benzo(b)fluoranthene and BAP were the second and third most frequently detected cPAHs, appearing in 27/121 and 24/121 soil samples, respectively. The concentrations of these compounds were lower than chrysene, with maximum concentrations of only 7.0 mg/kg for benzo(b)fluoranthene and 4.8 mg/kg for BAP. Benzo(b)fluoranthene exhibits a relative potency 10 percent that of BAP. Table II-1 summarizes the relative detection frequencies of cPAHs.

Table II-1 - Concentrations and Occurrence of Individual cPAHs

cPAH[1]	Detection Frequency	Maximum Concentration in mg/kg
Benzo(a)anthracene	22/121	8.6
Benzo(a)pyrene	24/121	4.8
Benzo(b)fluoranthene	27/121	7.0
Benzo(k)fluoranthene	17/121	2.3
Chrysene	40/121	14.0
Dibenzo(a,h)anthracene	8/121	0.5
Indeno(1,2,3-c,d)pyrene	19/121	1.6
Total cPAHs	48/121	37.0

Note:
[1] These seven PAHs are considered probable human carcinogens by EPA (IRIS, 1994).

Conclusions

Bunker C detected on the Site was found in two forms, a viscous product associated with the powerhouse and pipeline, and weathered Bunker C found in the Area 7 and Area 16 kettles. Interim source removal has removed the majority of Bunker C product associated with the pipeline. Weathered Bunker C was confined to surficial soils in Areas 7 and 16.

Based on soil leachability testing, residual TPH is low mobility and does not represent a TPH source to groundwater.

Although all seven cPAHs were detected in various site samples with elevated Bunker C, chrysene, one of the least potent of the cPAHs, exhibiting a potency of 0.1 percent of that of BAP, was the predominant cPAH detected on the Site.

Thus, the Bunker C at the Site is comprised of predominantly less mobile and less toxic cPAHs (Appendix IV).

APPENDIX III
DEVELOPMENT OF cPAH SOIL CLEANUP LEVELS FOR DESIGNATED LAND USES AT THE SITE

Soils with residual TPH/cPAH are contained within areas where the future land use may be either residential or recreational (although TPH/cPAH has not been detected in the zoned industrial areas of the Site, an industrial cleanup level has been developed in this appendix). This appendix describes the rationale and procedures used to develop cleanup levels for cPAH that will be protective of human health for these land uses.

Basis for Exposure Assumptions

Land Use. Following Site development, the non-industrial areas will include residential and recreational use areas. Recreational land use will include both a golf course and open space.

cPAH cleanup levels were generated for an industrial scenario and three exposure scenarios: golf course, open space, and residential. Note, however, that current development plans do not include residential areas where cPAH has been detected. Different exposure assumptions are applied in each scenario to account for the most likely individuals and activities producing the potential for exposure.

During golf course development, residual constituents in soil will be covered by one to two feet of topsoil in order to support course turf against the extremely rapid drainage of the native soils (Cummock, 1993; D'Aboy, 1993; Griswold, 1993). The only potential for exposure to the subsoils beneath the turf and imported topsoil would be infrequent activities requiring maintenance workers to dig through the barrier into the subsoils. Golfers and other visitors (e.g., trespassers) would not have contact with the subsoils. The cPAH cleanup level for golf course land use is derived from assumptions appropriate to a golf course maintenance worker.

In open space or green belt areas, residual soils may be available for direct contact, but not through activities typically associated with soil contact such as gardening, landscaping, or incidental ingestion by very young children (i.e., children less than six years old, who are typically assumed to incur the greatest levels of intake through soil contact, will be less likely to roam unattended through open space areas). Older children may represent the most likely, potentially exposed subpopulation, since they may roam through open space areas more freely than younger children. The DNT cleanup level for open space land use is intended to protect all children visiting open space areas, so the cleanup level was calculated using

parameters for a younger (0-6 year old) child in a recreational setting. This will be conservative for the older child.

The cPAH cleanup level for residential land use is intended to protect the younger (0-6 year old) child as a sensitive receptor, so the cleanup level was calculated using parameters typical for a child resident. Note again that cPAH has not been detected in areas currently planned for residential development.

The cPAH cleanup level for industrial land use is intended to protect an adult worker assumed to have regular and frequent (daily, occupational) contact with Site soils.

Ranges in risk-based cleanup levels. Recent risk assessment policy guidance (EPA 1992a) recommends development of risk ranges to describe potential risks from constituents at hazardous waste sites, and to inform risk management decisions for those sites. Risk ranges describe and account for uncertainty in risk assessment methods, and provide perspective on the upper-bound estimates of risk conventionally presented in risk assessments. Risk management is considered appropriate when predicted carcinogenic risks are in the range between one-in-one-million (10^{-6}) and one-in-ten-thousand (10^{-4}). In general, management of risks below the one-in-one-million threshold is unwarranted, whereas abatement of risks above the one-in-ten-thousand level is (usually) considered unnecessary.

Similarly, risk-based cleanup levels may be derived by rearranging equations used to estimate risk, and solving the equations for the concentration term associated with a pre-specified risk threshold (e.g., one-in-one-million). The concentration term is then regarded as the cleanup level associated with that threshold. Cleanup levels derived from rearranged risk algorithms are subject to the same types and degrees of uncertainty that apply to estimates of risk. Therefore, it is appropriate to generate a range of cleanup levels for consideration in the risk management process. The ranges of cleanup levels established in this document are based on a risk threshold between 10^{-6} and 10^{-5} for residential, open space, and golf course land use, and 10^{-5} and 10^{-4} for industrial land use.

Derivation of the Cleanup Levels

Soil cleanup levels for BAP are based on protection against potential carcinogenic effects. The carcinogenic potential of cPAH is conservatively represented by benzo(a)pyrene (BAP), the most potent cPAH (see below).

Two exposure routes are considered in the development of cleanup levels for cPAH: soil ingestion and dermal contact with soil. The cleanup levels

are calculated using equation 1. This equation is developed from exposure equations provided in Exhibits 6-14 and 6-15 in RAGS (EPA, 1989) by simultaneously solving the equations for the concentration in soil.

$$CS = \frac{Risk \times BW \times AT}{CPF \times CF \times FI \times EF \times ED \times \left[\left(IR \times ABS_i\right) + \left(SA \times AF \times ABS_d\right)\right]} \quad (1)$$

Tables 1 and 2 define the parameters in equation 1, and provide the values and references used for each land use. Values are based on estimates of central tendency for most parameters such that exposure, averaged over a lifetime, will produce an incrementally increased risk of cancer equal to the risk management threshold given as the "risk" parameter.

Table 1: Parameters Used to Calculate Cleanup Levels.

PARAMETER	DESCRIPTION		ECT RES	a	ECT OS	b	ECT GC	c	ECT IND	d
Risk	Acceptable risk level (unitless)	e	←		1E-5 to 1E-6		→		1E-4 to 1E-5	
BW	Body weight (kg)	f	15		15		70		70	
AT	Averaging time – carcinogens (days)	f	25550		25550		25550		25550	
CF	Conversion factor (mg/kg)	g	1E-6		1E-6		1E-6		1E-6	
FI	Freqency of intake (percent)	h	100		100		100		100	
EF	Exposure frequency (days/year)		275	i	52	j	36	k	250	f
ED	Exposure duration (years)		3	l	3	l	9	m	9	m
IR	Soil ingestion rate (mg/day)		63	n	63	n	26	o	26	o
SA	Skin surface area (cm2)	p	800		800		2000		2000	
AF	Soil to skin adherence factor (mg/cm2)	p	0.2		0.2		0.2		0.2	

NOTES

a. RES represents residential land use. The most exposed individual is a child.
b. OS represents open space land use. The most exposed individual is a child.
c. GC represents golf course land use. The most exposed individual is an adult.
d. IND represents industrial land use. The most exposed individual is an adult.
e. Two iterations were completed for RES, OS and GC: one at a risk threshold of 10^-5, and one at 10^-6. For IND, iterations were at 10^-4 and 10^-5.

Table 2: cPAH-specific Parameters Used to Calculate Cleanup Levels.

PARAMETER	DESCRIPTION	cPAH	
CPF	Cancer potency factor (mg/kg-day)^-1	7.30	a
ABSi	Gastrointestinal absorption factor (percent)	100	
ABSd	Dermal absorption factor (percent)	2.3	b

NOTES
a. From Huether (1993).
b. EPA Region 10, February, 1991 as cited in Eagle Harbor Revised Risk Assessment, 1991.

The U.S. EPA has acknowledged the use of certain average exposure assumptions in managing potential risks from carcinogens (EPA, 1991b). The basis of this recommendation is that protection against carcinogenic effects relies on a model of long-term exposure. Long-term exposure is best approximated using average values rather than extreme values, since the latter have "no consistent relationship" with long-term exposure. In order to account for uncertainty in some exposure parameters, upper-bound values are used for these parameters to assure a conservative approach to human health protection. Several sources of uncertainty for which conservatism is maintained are discussed below.

cPAH Potency. The carcinogenic potency of cPAH as a class is conservatively represented by the toxicity of benzo(a)pyrene (BAP). However, of the seven PAHs considered to be carcinogenic, BAP is the most potent. One cPAH is as potent as BAP; the other five are substantially less potent (10 to 1,000 times less potent). Because of this, toxicity equivalence factors (TEFs) may be applied in risk assessments when specific cPAHs are identified (EPA 1993).

The carcinogenic potency factor for BAP was used to develop cleanup levels at the Site. However, the predominant cPAH at the Site is chrysene, which is one-thousand times less potent than BAP. Therefore, use of the BAP potency factor is very conservative.

Fractional Intake from Specific Source Areas. The FI term as provided in Risk Assessment Guidance for Superfund (RAGS; EPA 1989) accounts for the fractional amount of soil that may be ingested on a daily basis from different sources. As applied in the Site risk assessment, the FI term describes the frequency of soil contact by an individual at the golf course or open space areas (FI in residential and industrial scenarios was assumed to be 100 %). The term accounts for the fact that only a portion of the surface area designated for golf course and open space use overlies Site areas with residual constituents in the soil. Furthermore, exposure at the

golf course will be limited to maintenance workers, who occasionally may be required to excavate soils to a depth penetrating the 1-2 foot barrier of amended topsoil that will overlie native soils. This barrier will prevent exposure to individuals walking over the golf course.

In the Site risk assessment, exposure to subsurface soils at the golf course or surface soils in open space areas was assumed to be random, occurring with a frequency of contact equal to the percentage of total land use surface area represented by a given Site area (e.g., the surface area of Area 16 equals 2% of the total, planned open space area; therefore, the probability of contacting surface soils in Area 16 during an open space visit is assumed to be 2%).

However, to derive cleanup levels for the Site, FI is assumed equal to 100% for both the open space and golf course scenarios. This is conservative, since it is highly unlikely that an individual will visit the same location (or all locations) during each visit, or that each excavation by a golf course worker will occur in the same place.

Using the parameters provided in the tables, the following cPAH cleanup level ranges are calculated for each land use:

- 1-10 mg/kg for residential land use;
- 5-50 mg/kg for open space land use;
- 20-220 mg/kg for golf course land use; and
- 30-300 mg/kg for industrial land use.

The ranges for residential, open space and golf course land use correspond to a risk threshold range between 10^{-6} and 10^{-5}; the range for industrial land use corresponds to a risk threshold range between 10^{-5} and 10^{-4}. These ranges are depicted graphically in Figure 1.

APPENDIX IV
HUMAN HEALTH TOXICITY OF TPH/PAHS

Carcinogenic Polycyclic Aromatic Hydrocarbons (cPAHs) are the most toxic component of Bunker C petroleum hydrocarbons. The MTCA regulation states that the cleanup level for TPH can be based upon the toxic fraction of the petroleum compound (WAC 173-340-740 (3)(a)(ii)(B)). As summarized in Appendix II, the most commonly detected cPAH was chrysene, one of the least potent of the cPAHs. Few studies are available concerning the toxicity of specific petroleum products; therefore, the following literature has been reviewed and relevant information compiled in the following section.

Bunker C Toxicity

Acute Toxicity. The American Petroleum Institute (API) commissioned Elars Bioresearch to study the acute toxicity of a variety of fuel petroleums (Beck et al., 1984). Four types of Bunker C fuel oils were studied. They were identified by specific gravity (sp) and sulfur content (%S): sp 0.99/2.7%S; sp 0.95/0.8%S; sp 0.92/0.2%S; and sp 1.04/1.2%S. Tests were performed to determine acute dermal and oral toxicity. Oral exposure to the Bunker C fuels with specific gravities of less than 1.0 demonstrated little toxicity with no increase in mortality associated with dosages up to 25 ml/kg body weight. The final Bunker C fuel, sp 1.04/1.2 %S, however, demonstrated measurable toxicity with an oral LD_{50} of 5 ml/kg body weight. Similar results were reported concerning dermal toxicity. These experiments illustrate the variability of toxicity associated with different formulations of Bunker C.

Acute Toxicity of Bunker C Components. Bunker C fuel oil is composed primarily of naphthenes, asphaltenes, saturated hydrocarbons, and aromatics (PAHs) (see Appendix II). cPAHs, the toxic component of Bunker C fuel oil, will be addressed separately.

Saturates, i.e., the saturated hydrocarbon chains with 9 or more carbons, have relatively little toxicity data. None of the long-chain (C-15 or greater) hydrocarbons are believed to be teratogenic, mutagenic, or carcinogenic (Clayton and Clayton, 1982). Extremely long chain compounds such as N-Pentadecane (C-15), 1-Octadecanol (C-18), and 1-Eicosanol (C-20) are considered relatively non-toxic with LD_{50}s greater than 15,000 mg/kg.

Asphaltenes also are considered to be relatively non-toxic. The International Agency for Research on Cancer (IARC) has evaluated the

data for asphaltenes and determined the data to be insufficient to classify these compounds as carcinogens (IARC, 1989). These compounds have also not been found to be mutagenic in mouse skin models (HSDB, 1994). In general, these compounds have little or no toxicity associated with them, even among road workers who used asphalt as a chewing-gum material (HSDB, 1994).

As with the other Bunker C components, naphthenes have very limited acute toxicity data. These data suggest that naphthenes are relatively non-toxic as well. Toxicity data on cyclopropanes, cyclobutanes, and cyclopentanes describe these compounds to only be toxic as simple asphixiants, although there is some evidence that cyclopropane may be carcinogenic (Lewis, 1992). Cyclohexane and ethylcyclohexane were demonstrated to have LD_{50}s of 30,000 and 64,000 mg/kg, respectively. These data suggest that the longer chain naphthenes will be relatively non-toxic compared with other components of Bunker C.

Carcinogenicity. The IARC has reviewed information concerning the carcinogenicity of a variety of petroleum fuels (IARC, 1989). Bunker C has not been demonstrated to be mutagenic in either bacterial or whole cell models. Bunker C has both positive and negative results in tumorigenic studies. Human epidemiology data are hard to interpret because of mixed exposures. As a result, the IARC has given Bunker C fuel a Group 2B ranking, possible human carcinogen. No ranking by the EPA is available at this time.

Bingham et al. (1980) linked the carcinogenicity of Bunker C with the fuel's PAH content. C3H mice were given dermal applications of 20 mg Bunker C twice weekly for an unspecified period of time (at least 59 weeks). Bunker C fuel containing 0.01 percent benzo(a)pyrene resulted in 2 out of 19 mice developing tumors over 59 weeks. In mice treated with Bunker C fuel containing 0.16 percent benzo(a)pyrene, 21 out of 25 developed tumors over 59 weeks (of which 12 were malignant). This study indicates that the carcinogenicity of Bunker C is largely dependent upon the PAH content of the particular fuel.

cPAH Toxicity

Carcinogenicity. Chrysene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, indeno(1,2,3-c,d)pyrene, and benzo(a)pyrene have all been determined to be complete carcinogens in animals by multiple routes of exposure. These seven cPAHs have been classified by the EPA as Group B2, probable human carcinogens (IRIS, 1994).

Benzo(a)pyrene is typically used as the representative PAH based on the availability of data. Neal and Rigdon (1967) reported a dose-related incidence of forestomach tumors in mice orally exposed to benzo(a)pyrene. An additional study by Brune et al. (1981) also demonstrated a dose-related incidence of tumors in sprague-Dawley rats. Slope factors for benzo(a)pyrene have been calculated using both a linear multi-stage model of carcinogenesis and a two-stage model. Four slopes, from 4.5 to 11.7, have been calculated. The EPA has presently established an oral carcinogenic slope factor of 7.3 $(mg/kg\text{-}day)^{-1}$ based on the geometric mean of these four previous slope factors (IRIS, 1994).

Relative Potencies of cPAHs. Benzo(a)pyrene (BAP) has been determined to be one of the most potent carcinogens of the cPAHs (EPA, 1986). Clement Associates (1988) used the two-staged carcinogenic model to develop potency estimates for various cPAHs that have demonstrated lesser carcinogenic potential than BAP. Quantitative risk estimates for mixtures of PAHs have often assumed that all cPAHs are as toxic as BAP, and that the carcinogenic effect of the mixture can be estimated by the sum of the effects of each individual cPAH. However, it has been documented that five of the seven cPAHs are less carcinogenic in animal studies than BAP (the toxicity of dibenzo(a,h)anthracene is assumed to be equal to BAP). Thus, assuming all cPAHs to be as toxic as BAP can result in an overestimation of risk (EPA, 1993a).

In 1993, based on the EPA's Office of Health and Environmental Assessment (OHEA) review of the Clement Associates (1988) report, OHEA issued provisional guidance for quantitative risk assessment of PAHs (EPA, 1993a), which is considered interim guidance. However, a recent memorandum originating from EPA Region 10 (EPA, 1993b) indicates that all the EPA regions agree that the new PAH policy would be formally adopted by EPA in the near future and that all the regions would use the policy as interim guidance for risk assessment of PAH compounds. Included in this guidance is an order of magnitude ranking of relative potency values for the individual PAHs that are recommended in order to provide a consistent approach in risk assessment.

Assessment of the risk of mixtures, using the relative potency approach, involves the following steps:

- Analytical determination of cPAHs;
- Multiplication of sample concentrations by their relative potencies to express concentration in terms of BAP equivalents, or relative potency concentrations (RPC);

- Summation of the RPCs to obtain total BAP equivalents in the sample;
- Determination of human exposure (expressed in terms of BAP equivalents); and
- Combining exposure with cancer potency information on BAP to estimate the cancer risk associated with exposure to the PAH mixture.

Table IV-1 summarizes the relative potencies for cPAHs (as presented in EPA, 1993a) detected at the Site.

Table IV-1 - Relative Potencies for cPAHs

cPAH	Relative Potency Factors
Benzo(a)Anthracene	0.1
Benzo(a)Pyrene	1.0
Benzo(b)Fluoranthene	0.1
Benzo(k)Fluoranthene	0.01
Chrysene	0.001
Dibenzo(a,h)Anthracene	1.0
Indeno(1,2,3c,d)Pyrene	0.1

As discussed in Appendix II, chrysene—the least potent of the seven cPAHs—is also the most prevalent cPAH at the Site. Therefore, sample cPAH results from Areas 7, 8, and 16 were normalized to total BAP equivalents using RPFs in order to more accurately reflect the relative potency of the cPAHs associated with the Bunker C detected on the Site. Normalized cPAH results were used to derive a cleanup level for TPH based on a correlation between TPH and cPAH concentrations (Appendix V).

Conclusions

The toxic fraction of the Bunker C product on Site is related to cPAHs. Much of the remaining content of Bunker C fuels is relatively non-toxic because it is composed of non-aromatic straight chain hydrocarbons. Because chrysene is the most prevalent but least potent of the cPAHs present at the site, it is appropriate to use EPA's interim relative potency

factors to estimate the potential cancer risk associated with exposure to these substances at the Site.

APPENDIX V
BUNKER C TPH CLEANUP LEVEL

In order to determine a cleanup level for Bunker C TPH detected on the Site, and recognizing that the risk posed by Bunker C is largely attributable to its cPAH components, correlation analyses were performed to assess the statistical relationship between cPAH and TPH concentrations. A correlation analysis was performed to determine an appropriate Site-wide cleanup level for Bunker C-derived TPH.

Regression Analysis to Determine Site-Wide Bunker C TPH Cleanup Level

An evaluation of the correlation between TPH and cPAHs was performed on samples collected from areas known to contain elevated concentrations of Bunker C. Regression analysis was performed on data collected from Areas 7, 8, and 16 combined. Data were combined from all Bunker C areas because: 1) there was limited cPAH data for area-specific correlations; 2) no significant differences were observed between area-specific correlations; and 3) the same product has been demonstrated to occur in all three areas (see Appendix II).

Cumulative total cPAH concentrations were assessed in the regression analyses. Sample cPAH results were normalized to total BAP equivalents in order to more accurately reflect the potency of individual cPAHs (see Appendix IV). The TPH concentrations associated with normalized cPAH concentrations of 1.0 and 10.0 mg/kg, the range of acceptable residential cleanup levels based on the toxicity of BAP, were calculated for the 95 percent upper confidence level.

Based on the regression analysis ($r^2=0.52$), normalized total cPAH concentrations of 1.0 and 10.0 mg/kg are equivalent to TPH residential cleanup levels of 3,100 to 27,000 mg/kg at the 95 percent confidence level (see Figure V-1).

Conclusions

Results indicate that cleanup levels of 3,100 to 27,000 mg/kg for Bunker C-derived TPH will achieve the cleanup goal of 1.0 to 10.0 mg/kg for cPAHs (residential land use) in Areas 7, 8, and 16. Normalized cPAH data accurately reflect the toxicity associated with the cPAHs detected on Site (see Appendix IV) and represent an accurate method for deriving a Bunker C cleanup level.

APPENDIX VI
GROUNDWATER, SURFACE WATER, AND LEACHABILITY DATA FOR TPH AND cPAHs

Groundwater Data

TPH Data for Groundwater. Total petroleum hydrocarbons (TPH; WTPH 418.1 analysis) have not been detected in any groundwater sample collected during the four rounds of RI groundwater sampling. The TPH data for groundwater are presented in Table VI-1.

Non-Carcinogenic PAH Data for Groundwater. Of the 129 groundwater samples collected during four rounds of RI groundwater sampling, no sample had confirmed detections of any PAH above the MTCA drinking water screening levels for non-carcinogenic (e.g., chronic toxicity) effects.

cPAH Data for Groundwater. One of the 129 groundwater samples collected during four rounds of RI groundwater sampling had an unconfirmed detection of total cPAHs above the 0.0001 mg/L MTCA screening level for total cPAHs (Table VI-2). During the September 1992 sampling round, one of two samples collected from monitoring well MW-8 had a reported total cPAH concentration of 0.0016 mg/L. However, this result was not confirmed by the field duplicate sample collected concurrently from MW-8, which had only a single cPAH (chrysene) detected at the detection limit (0.00001 mg/L). The discrepancy in results between this set of duplicate samples suggests possible sample contamination during sample handling in the field or laboratory. This is further supported by the lack of cPAH detections in groundwater samples or field duplicates from MW-8 in any of the other groundwater sampling rounds, either before or after the September 1992 sampling round. Detected total cPAH concentrations also have not exceeded the 0.0001 mg/L screening level in any other groundwater samples collected during the RI. Based on these data, the single unconfirmed detection of cPAHs in MW-8 above the screening level is not considered representative of groundwater quality at this location or elsewhere at the Site.

Chrysene has been detected inconsistently in groundwater samples from 11 monitoring wells (excluding the September 1992 sample from MW-8) at concentrations marginally above the MTCA Method B screening level of 0.000012 mg/L (Table VI-2). As discussed in Appendix IV, the individual cPAH screening levels are based on benzo(a)pyrene toxicity. Because benzo(a)pyrene is a more potent carcinogen than chrysene (by three orders of magnitude), the individual cPAH screening level is highly conservative for chrysene, which is the least potent of the seven cPAHs.

The chrysene detections occur infrequently in different monitoring wells, including well MW-14 located along the eastern (hydraulically upgradient) edge of the Site. The detected concentrations are very low, ranging from 0.00002 to 0.0001 mg/L, with an average of 0.00003 mg/L relative to the detection limit of 0.00001 mg/L. Furthermore, chrysene is not detected consistently at a given well over time (detected in only one of the 11 wells in more than one of the four sampling rounds). Statistical testing (a Fisher's Exact Test) indicates that the proportion of chrysene detections in on-site monitoring wells (16/129) is not significantly different (at $p = 0.05$; 95% confidence level) than the proportion of detections in background wells (0/12).

Benzo(b)fluoranthene and dibenzo(a,h)anthracene were also each detected in one groundwater sample (other than the September 1992 sample from MW-8) at concentrations marginally above the individual cPAH screening level (Table VI-2).

It should be noted that the RI analyses' very low-level detection limits for individual cPAHs in water (0.00001 mg/L) are essentially the same as the screening level for individual cPAHs (0.000012 mg/L). As a result, almost any detection of an individual cPAH in groundwater is above the screening level. Furthermore, the individual cPAH screening levels are below practical quantitation limits (PQLs) of 0.0002 to 0.002 mg/L as defined by Ecology (Ecology, 1993).

In any event, all samples in which an individual cPAH was detected (other than the September 1992 sample from MW-8), had a total cPAH concentration at or below the 0.0001 mg/L screening level for total cPAHs.

The screening levels for individual cPAHs are highly conservative since they are based on benzo(a)pyrene toxicity (discussed in Appendix IV). Chrysene, not benzo(a)pyrene, is the only cPAH detected in more than one groundwater sample collected from the Site (excluding anomalous September 1992 sample from MW-8). Because a screening level based on chrysene toxicity would be 0.012 mg/L (0.000012 mg/L/0.001 Relative Potency Factor [RPF]; refer to Appendix IV), the MTCA drinking water screening level for total cPAHs (0.0001 mg/L) is protective of human health and the environment at the Site.

Surface Water Data

TPH and ncPAH Data for Surface Water. No TPH or non-carcinogenic PAHs were detected above MTCA screening levels in any of the four rounds of RI surface water sampling.

cPAH Data for Surface Water. cPAHs were detected at a concentration above the most stringent surface water screening level in one surface water sample; however, the data indicate that the single exceedence was the result of elevated sample turbidity created during sampling.

In the December 1992 sampling round, low concentrations of cPAHs were detected in the surface water sample from sampling location SW-1 near the mouth of Sequalitchew Creek (Table VI-2). Six of seven individual cPAH concentrations (0.00006 to 0.00023 mg/L) were above MTCA screening levels (0.000031 mg/L based on benzo(a)pyrene toxicity). Because seasonally low water conditions occurred at SW-1 during the December 1992 sampling round, greater than usual sediment was stirred up during sampling, resulting in elevated total suspended solids (TSS) in the sample. The TSS value in this sample was 160 mg/L, an order of magnitude higher than all other TSS values measured from the SW-1 location. Because cPAHs have relatively low solubilities, the low level cPAH detections are likely related to the higher levels of particulate matter (TSS) in the sample.

No cPAHs were detected in any other surface water sample from the four rounds of sampling, indicating that the single detection is not representative of surface water quality at the Site.

Leachability Data

The lack of petroleum compounds (TPH and PAH) detected in groundwater or surface water is consistent with the low degree of leachability measured during toxicity characteristics leaching procedure (TCLP) testing for these compounds in Site soils.

Nine soil samples collected from Area 8 (Bunker C-derived) were tested for TPH leachability using the TCLP test (EPA Methods 1311/418.1). The TPH concentrations in the nine soil samples submitted for TCLP analysis ranged from 800 to 19,000 mg/kg. In addition, one of the samples was tested for TCLP PAHs. The TCLP test employs a much more rigorous leaching procedure than would be representative of natural site conditions (e.g., leaching due to rainwater infiltration). As a result, the TCLP results are conservative since they overestimate leachability relative to actual site conditions. The TCLP TPH and PAH results are summarized in Table VI-3.

Leachable total petroleum hydrocarbons (TPH), under the rigorous TCLP procedure, were not detected in samples with TPH concentrations up to 11,000 mg/kg. The only detected leachable TPH (16 mg/L) of the nine samples tested occurred in the sample containing the highest TPH

concentration of 19,000 mg/kg. No leachable cPAHs were detected in the Area 8 soil sample containing 6,900 mg/kg TPH.

Literature-derived values for cPAH partition coefficients provide additional support that residual hydrocarbon concentrations at the Site are protective of groundwater. Table VI-4 provides literature values for log K_{oc} (normalized organic carbon partition coefficient) for the cPAH compounds and an average measured organic carbon content for Site soils (fractional organic carbon content, f_{oc}). The soil:water partition coefficients (K_d values) for cPAHs were estimated by the expression $K_d = K_{oc} \times f_{oc}$. The estimated cPAH K_d values range from 9,600 to 1,205,000 (Table VI-4). Using the lowest estimated K_d value of 9,600 L/kg, a cPAH soil screening level for protection of groundwater (based on the conservative benzo(a)pyrene screening level) can be calculated as follows:

Soil conc. (mg/kg) = groundwater screening level (mg/L) x K_d (L/kg) x DAF
= (0.000012 mg/L) (9,600 L/kg) (100)
= 12 mg/kg

As discussed in the lead cleanup summary, EPA determined during its development of the TCLP regulations (55 FR 11803) that a dilution/ attenuation factor (DAF) of 100 is appropriate for the full range of constituents in the TCLP list, many of which are more mobile in the subsurface than cPAHs.

A total cPAH concentration of 12 mg/kg corresponds to a Bunker C-derived TPH concentration of 7,600 mg/kg (with 95% confidence; refer to Appendix V for TPH/cPAH regression analysis). This calculated TPH concentration is consistent with the fact that no leachable cPAHs were detected in a sample with 6,900 mg/kg Bunker C-derived TPH. This evaluation, with the TCLP data, supports 7,600 mg/kg TPH (Bunker C-derived) as protective of groundwater at the Site. All areas with Bunker C TPH sources have average concentrations (arithmetic mean and 95% UCL) below 7,600 mg/kg (refer to Tables I-1 and I-2 in Appendix I).

No areas of the Site have an average (arithmetic mean) cPAH concentration above 12 mg/kg. In fact, only two of 111 samples collected from the Site have detected cPAH concentrations above 12 mg/kg (one from Area 16 and one from Area 26). Because of the numbers of PAH samples and proportions of detections, the 95% UCL for cPAHs in these areas default to the maximum concentration according to MTCA statistical guidance (18 mg/kg in Area 16, and 37 mg/kg in Area 26; Table I-3 in Appendix I). Groundwater quality data from monitoring wells located immediately downgradient of Area 16 (MW-2, MW-3, and MW-5) and

Area 26 (MW-6) indicate no adverse impact to groundwater from TPH or cPAHs in these areas. Furthermore, cPAH results from samples collected below a depth of 1 foot in Area 16 (results provided in RI Deliverable I; Hart Crowser, 1992) indicate that the cPAHs, like the TPH, is limited to surficial soils impacted by Bunker C residue, i.e., there has been negligible vertical transport of cPAHs.

Although current MTCA guidance requires a single maximum sample result to represent average cPAH concentrations in Areas 16 and 26, all available data indicate that cPAHs in these areas, or in any area of the Site, do not pose a risk to groundwater or surface water.

Conclusions

Historical (pre-interim source removal) TPH and cPAH concentrations in soil have not adversely impacted groundwater or surface water at the Site. Evaluation of site-specific TCLP data and cPAH partition coefficients (K_d) supports a TPH concentration for Bunker C-derived petroleum concentrations of 7,600 mg/kg for protection of groundwater. Following interim source removal, no average concentrations of Bunker C-derived TPH are above 7,600 mg/kg. Furthermore, cPAH concentrations in soil do not pose a risk to groundwater or surface water. Therefore, remaining soils will not adversely impact groundwater or surface water quality at the Site in the future.

Notes:
- ND — Not detected (cPAH detection limits ranging from 0.00001 to 0.00005 mg/L; ncPAH detection limits ranging from 0.00001 to 0.00002 mg/L).
- NDE — Not detected (estimated cPAH detection limits ranging from 0.00001 to 0.00005 mg/L; estimated ncPAH detection limits ranging from 0.00001 to 0.00002 mg/L).
- J — Estimated value.
- (a) — Total represents the sum of detected values only.

APPENDIX VII
POTENTIAL ECOLOGICAL RISK OF TPH/cPAH

A quantitative ecological risk assessment was performed to estimate the potential risk posed by TPH/cPAH in soils at the Site to ecological receptors.

cPAHs

The ecological risk assessment for cPAHs used conservative models to approximate plant and animal uptake of cPAHs to derive potential doses for indicator species and evaluate risk. These methods are briefly summarized below.

Soil total cPAH concentrations were used as model inputs, and different exposure scenarios were simulated using a weighted statistical model. Soil cPAH concentrations were first normalized to benzo(a)pyrene equivalents (Appendix IV). Exposure concentrations for smaller animals were determined by calculating the upper confidence limit on the arithmetic mean (95% UCL) for individual areas of concern. Exposure concentrations for higher trophic animals were modeled by calculating the area weighted average for normalized cPAHs from sections of the Former DuPont Works Site and from the Site as a whole. The 95% UCL was then calculated for each weighted average. The area weighted approach provides a quantitative method for estimating cPAH exposure from animal foraging behavior.

The indicator species selected for the risk assessment included the Townsend Vole, Blacktail Deer, Red Fox, Red-tailed Hawk, and the Mallard Duck. Tasca et al. (1989) developed equations and assumptions to estimate daily intake of food, water, and incidentally ingested soil. The Department of Agriculture (DOA, 1985) catalogued the ranges and behaviors of indicator species. Plant uptake factors were derived from algorithms developed by Travis and Arms (1988) using benzo(a)pyrene as the modeled compound.

Based on this approach, daily chemical intakes of cPAHs were calculated for individual indicator species. These daily chemical intakes were compared against a laboratory No Observable Adverse Effects Level (NOAEL) for benzo(a)pyrene reported by Neal and Rigdon (1967). A hazard quotient was calculated for each indicator species by dividing the daily cPAH uptake by the reported NOAEL.
