1 Introduction

Aspect Consulting, LLC (Aspect) prepared this Performance Monitoring Report to evaluate the performance of cleanup actions implemented to address arsenic, zinc, and petroleum hydrocarbon occurrences in groundwater at the Barbee Mill Site (Site). The Site includes portions of the following properties:

- The former Barbee Mill Property (Barbee Property), which is currently owned by Conner Homes at Barbee Mill LLC, and is located at 4101 Lake Washington Boulevard North in Renton, Washington;
- The Quendall Terminals Property, located north of the Barbee Property; and
- State-owned aquatic lands of Lake Washington, located west of the Barbee Property.

Cleanup actions at the Site are described in the draft *Interim Action Design and Implementation Report* (Aspect, 2010a) and include the following activities to address arsenic and petroleum in groundwater:

- Removing soil from the Site exceeding Washington State Model Toxic Control Act (MTCA) Method A cleanup levels for arsenic and total petroleum hydrocarbons (TPH) and MTCA Method B cleanup levels for zinc.
- Installing a Passive Attenuation Zone (PAZ) along the downgradient boundary of the Barbee Property to prevent arsenic above the Site cleanup level from migrating off the Barbee Property.
- Installing a Groundwater Extraction and Treatment (Pump-and-Treat) System upgradient of the PAZ to remove additional arsenic mass from groundwater to enhance performance of the PAZ.
- Installing a network of monitoring wells and piezometers to evaluate performance of the PAZ and Pump-and-Treat System.

A Site plan showing the layout of the PAZ, Pump-and-Treat System, and monitoring well network is provided on Figure 1. Groundwater monitoring at the Site is ongoing in accordance with the *Performance Monitoring Plan* (Aspect, 2010b).

This report was prepared in accordance with Agreed Order DE 5396, dated December 1, 2009, and including Amendment 1 dated December 16, 2010, and Amendment 2 dated May 30, 2012 (AO), between Barbee Mill Co., Inc. and the State of Washington Department of Ecology (Ecology). The AO requires evaluation of remediation performance and reevaluation of restoration time frame on an annual basis. Performance of Site remedial actions through June 2016 was evaluated in the previous performance monitoring report (Aspect, 2016). This report documents the performance monitoring data collected through December 2016, evaluates the performance of the remedial actions by comparing monitoring data with remedial objectives, and updates the estimate of the Site restoration time frame.

The report is organized as follows:

- Section 2 – PAZ Performance Monitoring
- Section 3 – Pump-and-Treat System Performance Monitoring
- Section 4 – Estimated Restoration Time Frame
- Section 5 – Conclusions and Recommendations

2 PAZ Performance Monitoring

Performance of the PAZ is evaluated by monitoring groundwater and porewater around and downgradient of the PAZ, and by inspecting the shoreline downgradient of the PAZ. Monitoring activities, results, and conclusions are provided below.

2.1 Groundwater Monitoring

Ongoing groundwater monitoring for the PAZ includes the following:

- Collecting groundwater samples from wells CMW-2S/2D, CMW-3, CMW-4S/4D, and CMW-5, and analyzing for the following parameters:
  - Dissolved arsenic, to monitor effectiveness of the PAZ at removing arsenic from groundwater.
  - Dissolved iron, pH, conductivity, dissolved oxygen, and oxidation/reduction potential (ORP), to evaluate changes to groundwater chemistry due to the PAZ.
- Collecting groundwater samples from monitoring well BH-29A and well points WP-1A and WP-8, and analyzing for the following parameters:
  - Dissolved arsenic, to monitor the rate of attenuation downgradient of the PAZ.
  - Dissolved iron, pH, conductivity, dissolved oxygen, and ORP, to evaluate changes to groundwater chemistry downgradient of the PAZ.
- Collecting groundwater samples at wells CMW-1 and CMW-6, located at either end of the PAZ, and analyzing for dissolved arsenic and iron, to evaluate capture of the arsenic plume.
- Groundwater elevation measurements at the above wells and well points and at piezometers PZ-1 and PZ-2, to estimate groundwater flow patterns.

The groundwater monitoring data is summarized in Table 1. Arsenic concentrations at each sampling location and estimated groundwater elevation contours from December 2016 are shown on Figure 2.

The objectives of the PAZ are as follows:

- To intercept arsenic in groundwater exceeding the cleanup level of 20 micrograms per liter (µg/L) at the Barbee Property boundary;
- To reduce arsenic concentrations in groundwater exiting the PAZ to less than 20 µg/L; and
- To not alter water quality in groundwater in such a way that would negatively impact aquatic life in Lake Washington.

Groundwater monitoring data is evaluated relative to these objectives below.

2.1.1 Arsenic Plume Capture

The PAZ alignment was based on arsenic concentrations in samples collected from multiple depths at 21 borings along the Barbee Property boundary during the 2006 design investigation, as summarized in the draft Design Report (Aspect, 2006). The arsenic concentration at boring AZ-17 (25 µg/L) was used to locate the south end of the PAZ while the arsenic concentration at boring AZ-9 (23 µg/L) was used to locate the north end of the PAZ. Although these concentrations were slightly above the site cleanup level of 20 µg/L, they were within the range of upgradient background concentrations (which were as high as 28 µg/L) used to calculate the cleanup level.

The PAZ's effectiveness at capturing arsenic in groundwater above the cleanup level is evaluated based on the arsenic concentrations at two monitoring wells (CMW-1, at the south end of the PAZ, and CMW-6, at the east end of the PAZ), and on the groundwater flow patterns for the Site (see Figure 2). Groundwater flow directions observed at the Site during the past two sampling events are very similar to those reported in the previous performance monitoring report, and do not exhibit significant seasonal variability.[1] Groundwater monitoring at CMW-1 and CMW-6 indicate the following:

- Arsenic concentrations at CMW-1 increased slightly after installation of the PAZ and slightly exceed the cleanup level. The concentration detected in December 2016 (62 µg/L) was slightly higher than detected in December 2015 (58 µg/L). Arsenic was not detected downgradient of CMW-1 during the most recent porewater monitoring event (Aspect, 2011), and the arsenic concentrations at CMW-1 have not exhibited a statistically significant increasing trend[2] since porewater monitoring was last conducted.
- Arsenic concentrations at CMW-6 increased after installation of the PAZ and exceed the cleanup level. Since May 2009, concentrations have fluctuated slightly, ranging between 110 and 240 µg/L. A downward trend has been observed since June 2011.

Although arsenic concentrations at CMW-1 and CMW-6 exceed the cleanup level, the removal of 55,000 tons of arsenic-contaminated soil from the source area in 2006, and ongoing flushing of residual contamination upgradient of the PAZ, is expected to eventually reduce arsenic concentrations at CMW-1 and CMW-6 to below the cleanup level. The Site restoration time frame is discussed in Section 4.

In accordance with the Performance Monitoring Plan, monitoring of arsenic at CMW-1 and CMW-6 and measurement of groundwater elevations at all Site monitoring wells is

[1] Anomalous water levels were measured at several wells and piezometers during the December 2015 monitoring event. Groundwater monitoring results for some wells also showed a slight increase in concentration during this same event. Monitoring wells and piezometers were redeveloped prior the June 2016 monitoring event, and water levels and concentrations measured in June 2016 were more consistent with historical data.

[2] Data were analyzed for trends using linear regression analysis performed at the 95% confidence interval as described in EPA (2009). Data were also log transformed or analyzed with a seasonal Kendall trend analysis where appropriate, as determined by a Shapiro Wilk test for normality, Rank Von Neumann test for seasonality, and seasonality test.

planned to be conducted annually. The proposed groundwater monitoring schedule is summarized in Table 2.

2.1.2 Arsenic Removal

The PAZ is designed to reduce arsenic concentrations in groundwater flowing through the PAZ by at least 95 percent. Downgradient of the PAZ, arsenic concentrations are expected to decline gradually (i.e., attenuate) as residual arsenic on soil desorbs into the treated groundwater. Below, we evaluate the arsenic removal by the PAZ and the attenuation of arsenic downgradient of the PAZ.

2.1.2.1 PAZ Treatment Effectiveness

Arsenic removal by the PAZ is monitored at six monitoring wells constructed downgradient of the PAZ. Four shallow wells (CMW-2S, CMW-3, CMW-4S, and CMW-5) are screened near the water table, and two deeper wells (CMW-2D and CMW-4D) are located downgradient of the two deeper sections of the PAZ. Based on the surveyed coordinates for the wells and the PAZ, two of the shallow wells—CMW-3 and CMW-5—are located within 1 foot of the edge of the PAZ, while the other wells are located approximately 5 to 8 feet away from the edge of the PAZ.

Arsenic concentrations at PAZ monitoring wells are summarized in Table 1 and on Figure 3. Concentrations at three of the four shallow wells—CMW-2S, CMW-3, and CMW-5—have consistently been below cleanup levels since the PAZ was installed. Based on the reductions from initial concentrations at these locations, the PAZ has removed 98 to 99.5 percent of arsenic from groundwater.[3]

Concentrations at the fourth shallow well—CMW-4S—have dropped over 97 percent (to 99 µg/L) compared to preremediation conditions. This concentration is above the cleanup level of 20 µg/L. As discussed in the previous performance monitoring reports, concentrations at CMW-4S are likely elevated due to arsenic desorbing from soil downgradient of the PAZ. Contaminant fate-and-transport modeling (see Section 4) indicates that a more gradual decline in concentrations downgradient of the PAZ is consistent with the desorption and gradual flushing of residual arsenic on soil.

Arsenic concentrations at the two deep wells (CMW-2D and CMW-4D) have also declined compared to preremediation conditions, but more slowly than at the shallow wells. Data from these wells have shown the following:

- At CMW-2D: Concentrations are 32 percent lower than before the PAZ was installed. Concentrations initially decreased sharply, but have increased since the Pump-and-Treat System was shut down in August 2011. This well was redeveloped prior to the June 2016 sampling event to ensure that the well screen is in good hydraulic connection with the deep aquifer. The post-

[3] Using initial concentrations as the basis for arsenic removal is a reasonable estimate for initial performance, but as monitoring proceeds, actual removal of arsenic by the PAZ may be different than estimated using this method because influent concentrations – those entering the PAZ – are not monitored. Influent concentrations are expected to decrease over time, due to the prior excavation action and the on-going Pump-and-Treat System. However, performance of the PAZ will ultimately be evaluated by the effluent concentrations, not the percent removal.

redevelopment arsenic concentrations declined slightly from 190 µg/L to 170 µg/L.

- At CMW-4D: Concentrations have been reduced 88 percent as of December 2016. Concentrations have varied considerably (between 300 and 1,700 µg/L) but have shown a consistent downward trend since the Pump-and-Treat System was shut down in August 2011. The variability shows some seasonal patterns, with the highest concentrations detected in December and the lowest concentrations detected in September of each monitoring year, based on three years of quarterly monitoring.

A slower response to PAZ treatment in the deeper system is not unexpected because groundwater flow in this unit is likely much slower than in the shallow unit, due to the presence of lower permeability sandy silt, silt, and peat layers. Slower groundwater flow rates provide slower flushing of residual arsenic downgradient of the PAZ.

In accordance with the Performance Monitoring Plan, and as summarized in Table 2, annual monitoring of arsenic at the six PAZ monitoring wells is planned. Site-wide average arsenic concentrations since 2011 have been the same in June and December; however, the rate of groundwater discharge to Lake Washington is highest in December due to precipitation recharge in the uplands and lower lake levels during the winter. Therefore, the next groundwater monitoring event is scheduled for December 2017.

2.1.2.2 Attenuation Downgradient of the PAZ

Attenuation of arsenic in groundwater downgradient of the PAZ is evaluated based on data at one monitoring well, BH-29A (located 180 feet downgradient of the PAZ), and two sediment well points: WP-1A (located 50 feet downgradient of the PAZ) and WP-8 (located 150 feet downgradient of the PAZ). The well points, which are located in Lake Washington and screened approximately 2 feet below mudline, represent locations furthest downgradient of the PAZ where elevated arsenic concentrations have been measured and, therefore, the location where arsenic concentrations are likely to remain elevated the longest (see restoration time-frame discussion in Section 4). Data are summarized in Table 1. Trends in arsenic concentrations at WP-1A and WP-8 are shown on Figure 3 and summarized as follows:

- WP-1A: Arsenic concentrations have declined 99 percent at this location since the PAZ was installed. Arsenic concentrations at this location have historically exhibited significant seasonal variation. A concentration of 6.5 µg/L was observed in December 2016.
- WP-8: This location was not sampled prior to PAZ installation. Arsenic concentrations at this well point have declined 60 percent since the well point was installed in May 2009 and exhibit a slight downward trend.
- BH-29A: This location was not sampled prior to PAZ installation. Arsenic concentrations have fluctuated between 210 and 490 µg/L. Concentrations have declined 46 percent since this well was first sampled in September 2009.

Based on the collective data, arsenic concentrations in groundwater downgradient of the PAZ are declining. Additional data are needed to evaluate trends at BH-29A. As

summarized in Table 2, annual monitoring of arsenic at WP-1A, WP-8, and BH-29A is planned in December 2017.

2.1.3 Effect of PAZ on Groundwater Chemistry

To determine the effect of the PAZ on groundwater chemistry, PAZ wells are monitored for iron and field parameters including pH, temperature, conductivity, dissolved oxygen, and ORP. Iron concentrations are summarized in Table 1 and field parameter data are summarized in Table 3. Results indicated the following:

- At locations downgradient of the PAZ where iron was analyzed before and after installation of the PAZ (CMW-3, CMW-4S, at CMW-4D), dissolved iron concentrations are below those measured before PAZ installation.
- Little difference in temperature, dissolved oxygen, or ORP was noted between wells downgradient of the PAZ (CMW-2S, CMW-2D, CMW-3, CMW-4S, CMW-4D, and CMW-5) and wells up- or cross-gradient of the PAZ (EW-1 through EW-8, CMW-1, and CMW-6).
- The average pH of groundwater was slightly higher downgradient of the PAZ (7.5) than upgradient of the PAZ (6.7).
- The average conductivity of groundwater was slightly lower downgradient of the PAZ (356.8 □s/cm) than upgradient of the PAZ (419.1 □s/cm).

This data is consistent with the expected performance of the PAZ, in which ongoing reactions with the iron is expected to slightly raise the pH and remove dissolved minerals (consequently lowering the conductivity).

Based on the collected data, the PAZ is not adversely affecting groundwater chemistry. As summarized in Table 2, annual monitoring of dissolved iron and field parameters at PAZ monitoring wells will continue.

3 Pump-and-Treat System Performance Monitoring

The Pump-and-Treat System became operational on June 3, 2009. The system was shut down on August 5, 2011, to evaluate the potential for arsenic concentrations in groundwater to increase (i.e., rebound) in the absence of pump-and-treat (termed 'the rebound analysis'). The rebound analysis is ongoing. An evaluation based on data through December 2016 is included in this report.

Performance monitoring for the rebound analysis included the following:

- Collecting water samples from extraction wells EW-1 through EW-8 for analysis of dissolved arsenic and iron. Data from these wells are summarized in Table 1. Trends in arsenic concentrations at these wells are shown on Figure 4.

The purpose of the Pump-and-Treat System is to remove arsenic from groundwater upgradient of the PAZ. The primary objectives of removing arsenic upgradient of the PAZ are: 1) to reduce the restoration time frame for the Site to less than 50 years; and 2) to reduce arsenic concentrations entering the PAZ to 400 µg/L (so that the PAZ design objective of 95 percent arsenic removal achieves the Site cleanup level of 20 µg/L). Restoration time frame is discussed in Section 4. Monitoring results and the results of the rebound analysis are described below.

3.1 Monitoring Results

Monthly effluent sampling and system operational monitoring were not conducted during the period covered by this report (July 2016 through June 2017) because the Pump-and-Treat System was not operated as part of an ongoing rebound analysis (i.e., evaluating the potential for arsenic concentrations in groundwater to increase in the absence of pump-and-treat). For the rebound analysis, groundwater monitoring was conducted for the following reasons:

- To identify long-term trends in arsenic concentrations upgradient of the PAZ and compare to model predictions of restoration time frame (see Section 4); and
- To allow evaluation of PAZ performance and long-term trends downgradient of the PAZ without groundwater pumping.

PAZ performance monitoring data will be used to evaluate the effectiveness of the installed remedy and to help evaluate alternatives for the upcoming Feasibility Study.

Arsenic concentrations at extractions wells are included in Table 1 and trendplots for each well are shown on Figure 4. The data indicate the following:

- At three extraction wells (EW-5, EW-6, and EW-7), arsenic concentrations have declined since the Pump-and-Treat System was shut down in 2011.

- Three wells (EW-1, EW-4, and EW-8) have not exhibited a significant increasing or decreasing trend[4] since the Pump-and-Treat System was shut down.
- An overall increase in arsenic concentrations was measured at wells EW-2 (from 130 to 160 µg/L), and EW-3 (from 140 to 240 µg/L), with a slightly increasing trend noted during the rebound analysis period; however, a slight decreasing trend has been noted at EW-2 since 2015.
- Overall, the average arsenic concentration at the eight extraction wells EW-1 through EW-8 have declined 60 percent during the pump-and-treat rebound analysis period, from 365 µg/L to 146 µg/L, between September 2011 and December 2016 (see Figure 6).

Based on the results, arsenic concentrations upgradient of the PAZ are declining in the absence of pump-and-treat. Observed trends are compared to model predictions in Section 4 below. Based on these preliminary results, continuation of the rebound analysis (i.e., leaving the system off and continuing groundwater monitoring in accordance with the schedule in Table 2) is recommended. Future groundwater monitoring data will be documented in progress reports submitted to Ecology.

Evaluation of the continued rebound analysis will be provided in the next performance monitoring report due to Ecology on July 31, 2018.

[4] Data were analyzed for trends using linear regression analysis performed at the 95% confidence interval as described in EPA (2009). Data were also log transformed or analyzed with a seasonal Kendall trend analysis where appropriate, as determined by a Shapiro Wilk test for normality, Rank Von Neumann test for seasonality, and seasonality test.

4 Restoration Time Frame

Upgradient of the PAZ, residual arsenic is being flushed out by clean groundwater flowing onto the Site. Downgradient of the PAZ, residual arsenic is being flushed out by clean groundwater treated by the PAZ. This section describes the estimated restoration time frame (i.e., the time for arsenic concentrations to achieve cleanup levels in groundwater) in these two areas.

Restoration time frames were estimated as described in the previous performance monitoring reports using a fate-and-transport model (Aspect, 2011; Aspect, 2012; Aspect, 2013; Aspect, 2014; and Aspect, 2015). The model-predicted concentrations (based on 2011 model calibration) and measured concentrations of arsenic at wells CMW-4S, CMW-5 and well points WP-1A and WP-8 are shown on Figure 5. The model predicted a faster decline than was observed at CMW-4S and a slower decline than was observed at CMW-5, WP-1A, and WP-8; as discussed in the previous monitoring reports, this is likely due to the following:

- Modeling artifact for CMW-5, which is located less than 5 feet from the PAZ. At this close distance, even the finer model grid (5-foot cell spacing) cannot provide sufficient resolution. Model grids of less than 5 feet were considered but were determined to not add additional precision due to uncertainty in model predictions of transport processes that occur over very short distances at model boundaries (such as the edge of the PAZ) where concentrations used in the model change dramatically.
- Actual groundwater conditions that vary from the simple model assumptions of uniform initial concentration, homogeneous soils, and equilibrium sorption.

The model (based on 2011 model calibration) estimated that restoration time frames (i.e., time after PAZ installation to achieve the arsenic cleanup level) downgradient of the PAZ are 21 years at WP-1A, 25 years at BH-29A, and 40 years at WP-8 under natural groundwater flushing (no pump-and-treat[5]). Based on a comparison of data collected since 2011 (when the Pump-and-Treat System was shut off) to model-predicted concentrations for the same time period (Figure 5), the model may be over-predicting restoration time frame at WP-1A and WP-8[6] (i.e., groundwater concentrations are dropping faster than predicted). However, there is some variability in the data and additional data is needed to confirm this trend. If this trend continues based on future monitoring, it may be appropriate to recalibrate the groundwater model and re-estimate restoration timeframe.

[5] As described in 2012 performance monitoring report (Aspect, 2012), a longer restoration time frame would be predicted if the Pump-and-Treat System is operated for an additional period in the future because pumping would slow the rate of groundwater flow downgradient of the PAZ (and, consequently, the rate of arsenic flushing).

[6] BH-29A has been monitored less frequently, so there are fewer data points to evaluate trends at this location.

In 2011, restoration time frames upgradient of the PAZ were estimated to be 39 years at EW-1 and 20 years at EW-8 without additional pump-and-treat. This was based on an average arsenic concentration upgradient of the PAZ of 244 µg/L as measured in June 2011. As of December 2016, the average upgradient arsenic concentration had declined to 146 µg/L. This decline is consistent with the model-predicted decline upgradient of the PAZ (see Figure 6); therefore, no recalibration of the model upgradient of the PAZ is recommended at this time. Continued monitoring is needed to evaluate long-term trends.

5 Conclusions and Recommendations

Site monitoring data indicate that remedial actions have greatly reduced arsenic concentrations at the Site. The PAZ is removing residual arsenic in groundwater migrating from the Barbee Property. More monitoring is needed to confirm continued treatment and to further refine predictions of restoration time frame.

Future PAZ performance monitoring will occur on an annual basis and we recommend performing the annual sampling in December. Since 2011, the average arsenic concentrations across the site measured in December/January and June sampling events are the same; however, the relative head difference between the uplands and Lake Washington is greater during the winter when lake levels are lower. Sampling during the season with the greatest relative head difference would correspond with the season of increased groundwater discharge to Lake Washington.

Progress reports are currently prepared on an annual basis. The next progress report will be submitted to Ecology within 30 days of receiving the analytical data from the December 2017 sampling event.

Additionally, we recommend continuing the rebound analysis by leaving the Pump-and-Treat System off and continuing groundwater monitoring. We will provide an evaluation of remediation performance and restoration time frame in the next annual performance monitoring report. The next annual performance monitoring report is due on July 31, 2018.

Notes:

[1] Results from ICP/MS analysis and Arsenic Hydride analysis

[2] Cleanup levels and performance standards identified in Performance Monitoring Plan (Aspect, in progress) and are based as follows

Arsenic: Cleanup level based on natural background concentration of arsenic in groundwater.

Zinc: Cleanup level based on current ARARs for fresh water, superseding the previous cleanup level of 105µg/L identified in Independent Remedial Action Plan (Hart Crowser, 2000)

TPH: Cleanup level based on MTCA Method A cleanup level for unrestricted use.

Iron: Performance standard is for the PAZ to not significantly elevate natural concentrations, which are naturally elevated due to reducing conditions created by peat deposits in Site soils.

Copper and Lead: Performance standard for PAZ is to not result in exceedance of surface water standard listed in table.

[3] Iron concentrations in samples collected prior to the PAZ being installed are not compared to the performance criteria.

[4] Iron concentrations in samples collected upgradient of the PAZ are not compared to the performance criteria.

[5] Results are for total/dissolved concentrations.

[6] WP-1A and WP-8 were damaged by debris and not sampled during the Sept 2011 monitoring event.

[7] Well casing was trimmed due to well monument subsidence.

[8] Well Points WP-1A and WP-8 were not located during the December 2012 monitoring event and were presumed destroyed. These well points were replaced at the same locations on January 22, 2013.

U =not detected at indicated reporting limit

bold = data collected during this reporting period

Blue italics indicates baseline sample from location closest to current sample location, as follows:

existing location	baseline location
CMW-1	AZ-16
CMW-2S	AZ-3
CMW-2D	AZ-18
CMW-3	RMW-01
CMW-4S	AZ-5
CMW-4D	HCMW-01D
CMW-5	AZ-11
CMW-6	AZ-9
WP-1A	WP-1B
PW-CMW-2	PW-M
PW-CMW-3	PW-N
PW-CMW-4	PW-WP1B

Highlighted cells indicate exceedance of cleanup levels

Notes:

[1] The 'Monitoring Year' begins in September of the indicated year (i.e., the 2017 monitoring year runs from September 2017 to August 2018). As discussed in Section 5 of this report, annual monitoring is scheduled to occur in December.

[2] Assumes pump-and-treat operation ends in August 2011 and is not restarted.

[3] Piezometers wil be monitored for water levels only in conjunction with site monitoring events.

[4] When the pump-and-treat system is not operating, a subset of extraction wells will be monitored to evaluate concentrations upgradient of the PAZ.

A Annual

-- No monitoring planned

Field parameters (temperature, conductivity, pH, dissolved oxygen, ORP) and water levels collected during each monitoring event
The monitoring program will be reevaluated in 2020

As Arsenic

Fe Iron

Notes:

1) An "X" indicates that a pump was turned "on" during the majority of the system operating period for the indicated month. However, flow contributions from individual wells were not measured.
2) The pump-and-treat system began operation on 6/3/09. Startup testing revealed that the line from well EW-8 did not produce water, apparently due to a line break.
3) When installed in May 2009, the pumps were set such that their tops were approximately 1.5 feet below the water table. On 8/10/09, the pumps in wells EW-6 and EW-7 were reset such that their bottoms were approximately 1.5 feet above the well bottom. On 9/9/09, the remaining well pumps were reset in the same manner.
4) The flow meter stopped working sometime between site visits on 8/10/09 and 9/1/09, apparently due to fouling of the in-line paddlewheel sensor. After cleaning the sensor on 9/2/09, flow meter function was restored. The volume of water pumped during this period was estimated, and the sensor was subsequently inspected on a monthly basis.
5) The break in the EW-8 line was located and repaired in early December 2009, and pumping from that well was initiated on 12/8/09.
6) The flow meter stopped working sometime between site visits on 12/8/09 and 12/22/09. The cause was determined on 1/15/10 - the inside of the 2-inch-diameter pipe housing the sensor was fouled to the point that the paddlewheel was shielded from the water flow. After cleaning the pipe, flow meter function was restored. Discharge flow rate was measured manually on 1/5/10, and the volume of water pumped between 12/8/09 and 1/15/10 was estimated. Subsequent monthly fouling inspections included the pipe as well as the paddlewheel sensor.
7) The system automatically shut down on 5/2/10 (est.) due to a clogged settling tank discharge line. The shutdown was discovered on 5/6/10. The discharge line was snaked out and the system restarted on 5/7/10.
8) The system was shut down on 6/8/10 after manual flow rate testing determined that the electronic flow totalizer was programmed incorrectly, resulting in low reporting of flow volumes. The totalizer was re-programmed and the system restarted on 6/15/10. KCIW was notified on 6/21/10, and issued a Notice of Permit Violation for Exceeding Maximum Daily Discharge Volume dated 9/14/10. The discharge volumes shown in this table have been corrected.
9) The system was shut down on 10/26/10 after an exceedence of the Daily Average limit for arsenic was received from the laboratory. A composite sample was collected immediately prior to system shutdown, and KCIW was notified. The arsenic concentration shown represents the average of the two October 2010 samples.
10) The system was restarted on 12/23/10 after a letter was received from KCIW regarding the October 2010 exceedence.
11) High arsenic results in December 2010 and January 2011 prompted the decision to clean out the settling tank. Accumulated sediment was removed from the tank on 3/10/11 and disposed of as non-hazardous waste.
12) The system was shut down on 4/15/11 after an exceedence of the Daily Average limit for arsenic was received from the laboratory. A grab sample was collected immediately prior to system shutdown, and KCIW was notified. The arsenic concentration shown represents the average of the two April 2011 samples.
13) After visiting the site, KCIW recommended that a "tee" be installed inside the settling tank on the gravity discharge line, and that additional monthly inspection and maintenance steps be completed. The "tee" was installed, and the system was re-started on 6/14/11 after approval was received from KCIW.

Legend

- Passive Attenuation Zone
- WP-6 — Well Point
- CMW-1 — Monitoring Well Location
- EW-7 — Extraction Well Location
- PZ-1 — Piezometer Location
- RS — Remediation System Utilities
- 21.36 — Groundwater Elevation (December 2016)
- 410 — Groundwater/Porewater Arsenic Concentration in µg/L (December 2016)
- U — Not Detected at Indicated Detection Limit
- 20 — Groundwater Elevation Contour (December 2016, Dashed Where Inferred)

Summary of Arsenic Monitoring Data December 2016

Barbee Mill

4101 Lake Washington Blvd. North, Renton Washington

Aspect Consulting	Jan-2017	BY: DIM/SCC	FIGURE NO. 2
	PROJECT NO. 050004	REV BY: SCC	

CAD Path: Q:\Barbee Mill\050004 Barbee Mill\2017-01 Progress Report\050004-03.dwg GW Contours and Summary Data || Coordinate System: NAD 1983 State Plane Washington North FIPS 4601 Feet || Date Saved: Jan 25, 2017 3:32pm || User: scudd

Figure 3 - Trends in Arsenic Concentrations in Groundwater at Monitoring Wells

Red line represents site cleanup level for dissolved Arsenic (20 ug/L)
Solid green Line represents PAZ installation, and dashed green lines represent the startup and shutdown of the Groundwater Pump and Treat System

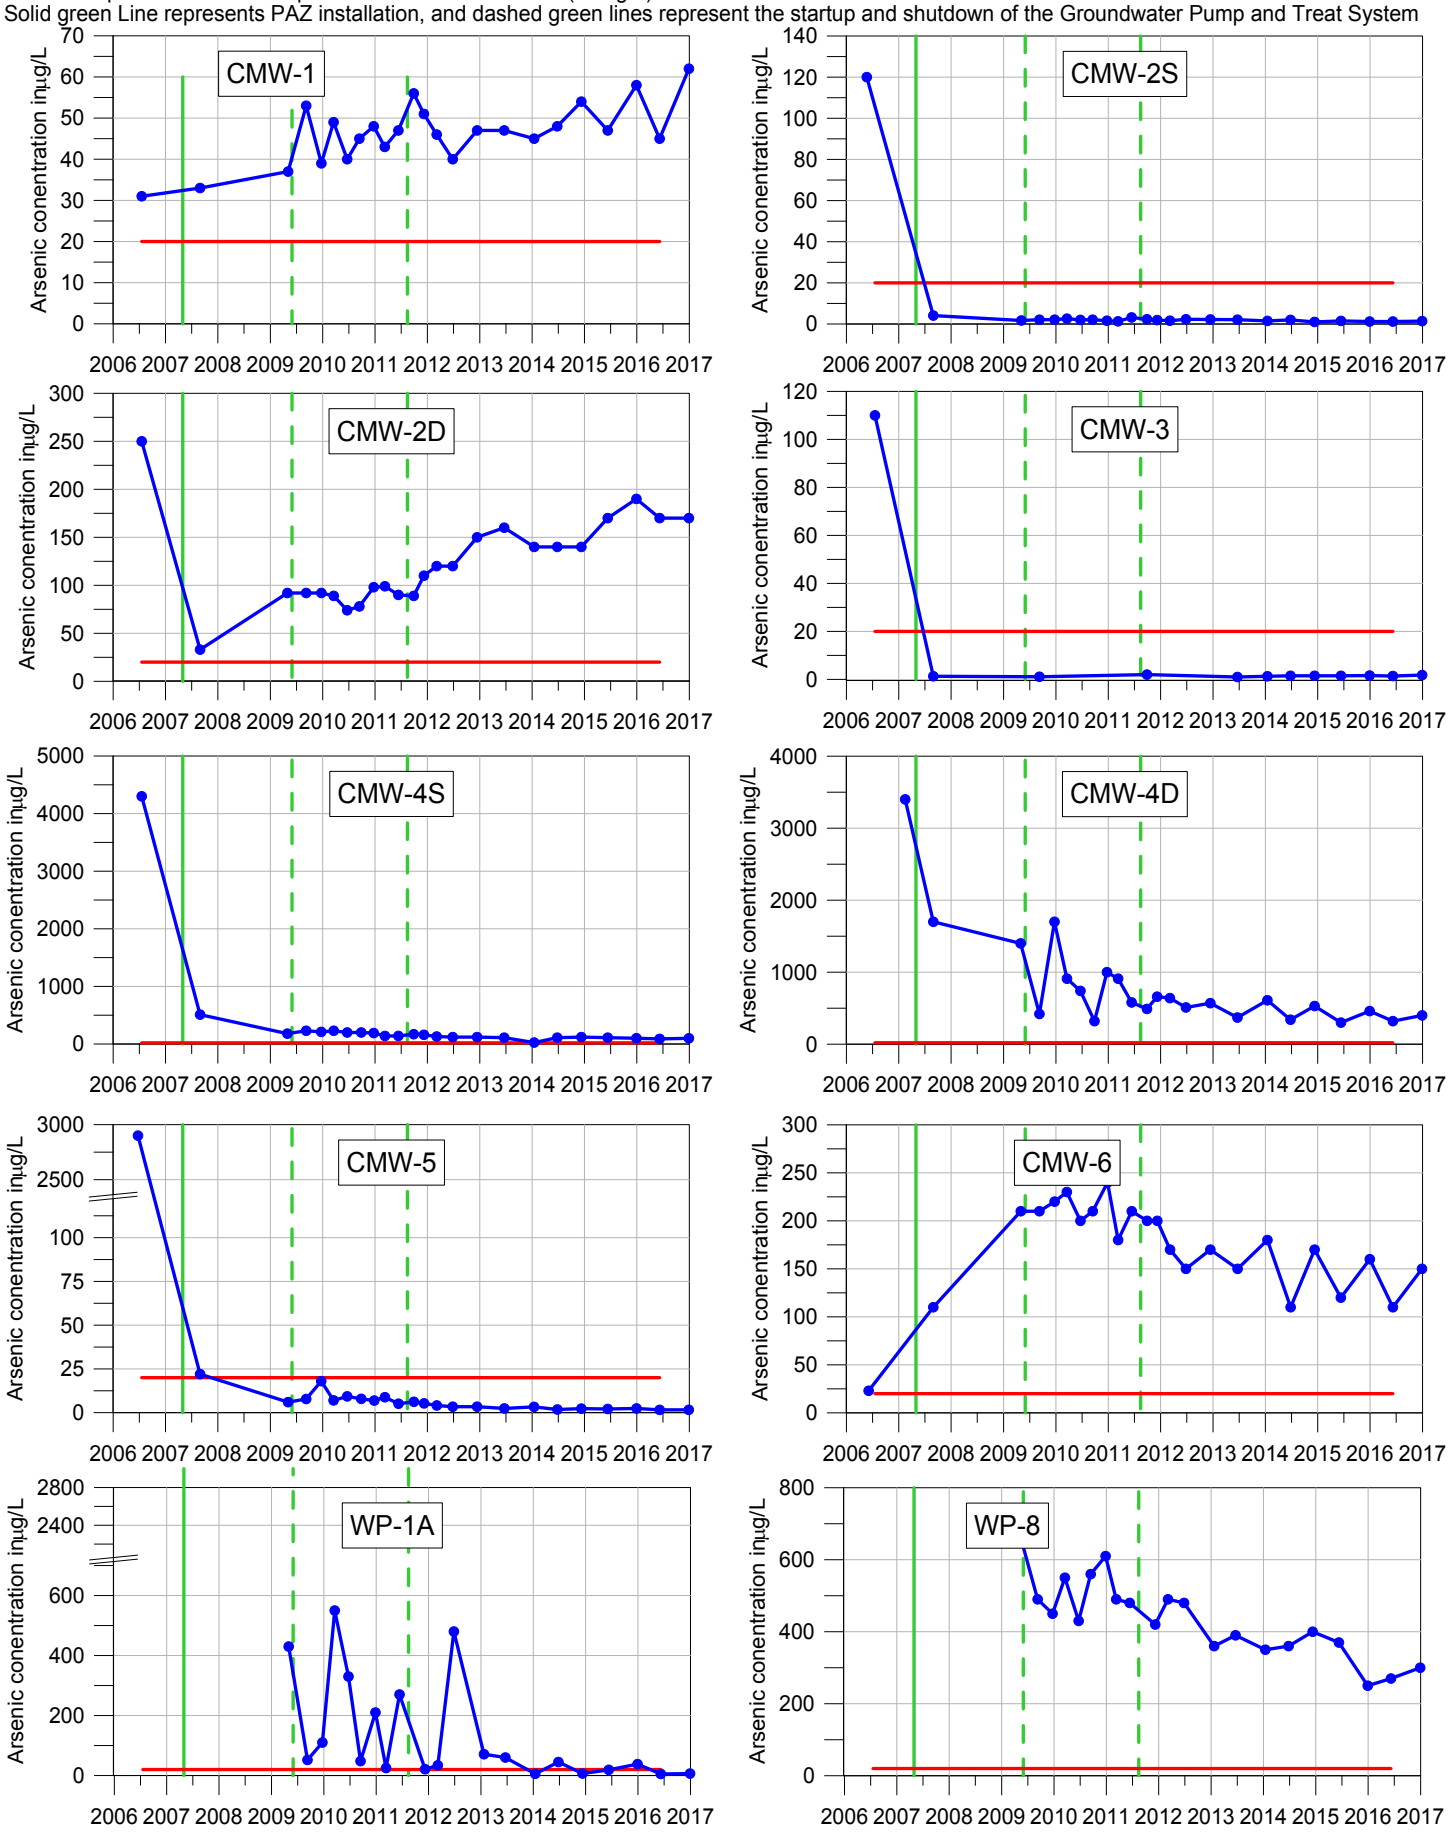

Figure 4 - Trends in Arsenic Concentrations in Groundwater at Extraction Wells

Red line represents site cleanup level for dissolved Arsenic (20 ug/L)
Dashed green lines represent the startup and shutdown of the Groundwater Pump and Treat System
Total arsenic results are displayed from 9/2009 to 6/2010, Dissolved arsenic results displayed from 9/2010 to present
Blue symbols represent samples collected while extraction well had not been operating during the month preceding sampling
Green symbols represent samples collected when extraction well had been operating during the month preceding sampling
