RE:

FOURTH QUARTER - GROUNDWATER MONITORING

Mac's One Hour Cleaners 10825 SE 176th Street Renton, Washington

Dear Mr. Radford:

Environmental Associates, Inc. (EAI) has completed the fourth of four (4) planned quarterly groundwater monitoring events as provided for in accordance with our proposal, dated August 17, 2011. All nine (9) monitoring wells (five on-site and four off-site) were sampled during this event.

Project Background

A dry-cleaners has operated as a tenant on the subject property since the 1960s. In 2009, the Client / property owner (Tri-Western Syndicated Investments) received notice from the west/southwest adjacent property owner (Bayview) that dry-cleaning solvents (tetrachloroethene or "perc" / PCE) had been discovered on their parcel and that they (Bayview) suspected that the source was the dry-cleaner on the subject property. In January / February 2010, four (4) initial groundwater monitoring wells (MW-1 through MW-4) were installed on the subject parcel to make a preliminary assessment of subsurface environmental conditions. That exploration confirmed the presence of PCE in both soil and groundwater at the subject property at concentrations above Washington State Department of Ecology (WDOE) target compliance levels for unrestricted land use. That preliminary assessment also identified the on-site dry-cleaner as a potential source for the encountered contaminants.

Associate Offices: Oregon / San Francisco Bay Area

Through the Spring / Summer of 2010, several additional phases of environmental study were performed on the Tri-Western parcel. These activities included geophysical surveys, sewer-line closed-circuit TV surveys, and additional phases of soil and groundwater assessment both within the dry-cleaners and in exterior areas of the property. These efforts identified two (2) suspected "source" areas of impacts by dry-cleaning solvent, including an area along a side sewer line along the western side of the building, and a less well defined area along a section of sewer pipe north-northeast of the subject building.

Prior to selection of a potential remediation approach, the next step in the remediation feasibility study process was to further assess the extent of the environmental impact. To facilitate this next phase of work, an access agreement was worked out between the two parcel owners over the Summer / Fall of 2010. One (1) additional monitoring well (MW-5) was installed on-site and four (4) monitoring wells (MW-6 through MW-9) were installed off-site on the adjoining "Bayview" parcel during November and December of 2010.

Following installation and sampling of the additional monitoring wells, the feasibility of several remediation and risk management approaches was evaluated. By mid Summer 2011, the approach favored by the Tri Western team was to initially perform active remediation by excavating a trench along the length of the western sanitary sewer line that served a floor drain inside of Mac's Cleaners. Leakage along the sewer line was suspected to be a primary source for the groundwater plume. The trench was anticipated to both physically remove some of the PCE-impacted soil at the source area and provide a means of applying remediation stimulating chemicals to hopefully reduce the mass of contamination both at the source and in down-gradient areas on and off the subject property.

In October 2011, the above-referenced trench was constructed and an initial application of remediation products intended to stimulate and enhance anaerobic bio-degradation was applied to the open trench. A network of perforated piping was set within the trench during the backfilling process to allow for future re-application of remediation products. Details regarding the trench construction and remediation product application were previously presented to the client under separate cover.

Scope of Work

To evaluate the performance of the initial application of remediation products, the following scope of work was adopted for execution on a quarterly basis (every three months) for four (4) consecutive quarters):

• Measure current depths to groundwater in all nine (9) study area monitoring wells (MW-1 through MW-9). Utilize the data to prepare an updated water table survey and groundwater flow interpretive map.

- Collect representative groundwater samples from each monitoring well using a low-flow micro-purging technique with a peristaltic pump. During well purging, a multi-parameter meter and flow through cell is used to collect basic geo-chemical data on groundwater conditions such as pH, temperature, conductance, dissolved oxygen, and oxidation/reduction potential.
- Submit all recovered groundwater samples to the project laboratory with analysis for chlorinated volatile organic compounds (CVOCs) by EPA test method 8260. Groundwater samples from MW-3 and MW-5 (nearest to the remediation trench) may also be analyzed for other parameters of interest such as chemical and biological oxygen demand, dissolved gases, and inorganic chemistry such as dissolved iron, nitrogen, and sulfate concentrations, which can be used to evaluate the effectiveness and down-gradient influence of the remediation products applied at the trench.
- Prepare a written summary report documenting field methods, observations, findings, and conclusions. Reports for the first, second, and third quarters will be brief with very little discussion and interpretation of the interim findings. At the conclusion of the fourth quarter, a more detailed report is intended to provide an expanded in-depth data analysis and project review.

Water Table Survey

The fourth quarter of groundwater monitoring was performed over a two-day period during October 23rd and 24th, 2012. Prior to micro-purging, the depth to groundwater below the top of each well casing was measured. These depths to groundwater along with the corresponding deduced elevations of the water table at each well location are recorded in Table 1.

Chart 1, attached, provides a hydrograph (i.e plotted water table elevation changes over time) for all nine (9) monitoring wells. Since quarterly groundwater monitoring began in December 2011, the hydrograph depicts a typical site-wide rise in water table elevations during the wetter winter and spring months, and falling water table elevations during the dryer summer and early fall months. Since the Spring of 2012, average groundwater elevations across the study site have continued to decline as visually discernable on Chart 1. At the time of the Fourth Quarter monitoring event average groundwater levels appeared to be at the lowest elevations since monitoring began in 2010.

Plate 3, Water Table Survey, presents a graphical representation of the shallow water table and deduced groundwater flow directions based upon the current geometry of monitoring wells. Examining Plate 3, groundwater flow appears to be westward with a slight northwesterly flow component in the vicinity of monitoring wells MW-7 and MW-9.

The groundwater flow regime appears generally consistent with prior surveys.

Groundwater Sampling - October 2012

The nine (9) monitoring wells were sampled between October 23rd and 24th, 2012. Prior to that, the monitoring wells were last sampled in June 2012.

Each monitoring well was first "micro-purged" utilizing a peristaltic pump equipped with a flow-through cell instrumented to monitor a variety of parameters including pH, water temperature, conductivity, dissolved oxygen, and redox-potential. Micro-purging continued until consecutive readings of the above parameters stabilized (i.e. varied less than 10 percent). The final readings for the above parameters for each monitoring well are presented in Table 2.

Once that the above measured parameters suggested that the extracted groundwater was representative of ambient conditions, groundwater samples were then transferred directly to laboratory-prepared glassware.

Laboratory Results - October 2012

The nine (9) groundwater samples were analyzed by the project laboratory for chlorinated volatile organic compounds by EPA test method 8260B. The laboratory results on presented in Table 3. Additionally, concentrations of PCE in groundwater are graphically presented on Plate 4.

During this current sampling event, PCE was detected in eight (8) of the nine (9) samples. Only five (5) contained PCE at concentrations above the Washington State Department of Ecology's 5 parts per billion (ppb) target compliance level. PCE was not detected in the groundwater sample recovered from MW-1 at concentrations above the laboratory's minimum detection limit. Wells MW-4, MW-8 and MW-9 contained detectable concentrations of PCE that were below the WDOE's target level.

During the current sampling event, the highest concentrations of PCE were observed in the "core-of-the-plume" monitoring wells MW-2, MW-3, MW-6, and MW-7, in which concentrations of PCE in the groundwater ranged between 130 to 170 ppb. The concentrations of PCE at these four (4) locations were all higher than the previous sampling event. Additional discussion regarding this observation is presented in the Fourth Quarter Annual Review section of this report.

In regard to VOC detections in groundwater at MW-5, cis-DCE continues to be present for the second consecutive quarter, while the concentration of PCE has remained relatively unchanged from the prior sampling event. Additionally, the redox-potential measured during the groundwater sample collection at MW-5 has remained negative, suggestive of a "reducing environment." These observations combined appear to suggest that the remediation products applied in the nearby "remediation trench" have extended the area of activity to include the vicinity of MW-5. The presence of degradation products such as cis-DCE further suggests that a reduction in contaminant mass of PCE is occurring at the suspected source area.

As summarized in Table 3, while groundwater samples from MW-1, MW-4, and MW-8 have contained detections of PCE (past or present), none have been in excess of the Washington State Department of Ecology's (WDOE's) target compliance level of 5 parts per billion (ppb). Monitoring wells MW-1 and MW-8 are both located along the southern margin of the study area. As such, monitoring well's MW-1 and MW-8 appear to continue to establish a partial southern limit of the PCE groundwater plume, as depicted on Plate 4, PCE In Groundwater as a red "dashed" line.

Fourth Quarter Annual Review - Summary and Discussion

Upon completion of the first full year of quarterly groundwater monitoring the following observations and expanded discussion are offered:

- In general dissolved contaminant concentrations across the study area are lower upon at the end of the four quarters than they were at the beginning.
- Within the past year the dry-cleaning facility operator removed the PCE-based dry-cleaning machine and has installed a newer "green-machine" that no longer uses chlorinated solvents. This facility operations detail would appear to significantly reduce the likelihood of ongoing or future releases of PCE contributing to the presently known environmental impairment.
- Concentrations of PCE within the "core" of the plume (measured at MW-2, MW-3, MW-6, and MW-7) were higher at the fourth quarter than they were during the prior third quarter sampling event. It is unclear at present if the increased concentrations were due to "stagnation" or "rebounding" which, if true, would signal the need to re-apply remediation products and perhaps consider expanding the treatment regime. Alternatively, the apparent "rebounding" in dissolved concentrations may simply be an artifact of the substantial loss of water in the groundwater system due to the unusually dry summer and fall experienced this past year. In short, the loss of water-table elevation may have acted to concentrate the residual dissolved contaminant mass, thus producing groundwater samples with higher contaminant concentrations. Continuing with regularly scheduled quarterly monitoring should resolve this uncertainty.
- Groundwater conditions in the vicinity of MW-5 appear to have become slightly reducing in terms of oxidation-reduction potential, a condition that is supportive of the strains of anaerobic bacteria that tend to enhance bio-degradation of chlorinated compounds. This appears to be a positive sign that the remediation products applied at the source area trench are beginning to expand the active zone of treatment down-gradient from the main trench alignment. The detection of degradation products such as cis-DCE in the groundwater at MW-5 beginning during the 3rd quarter further suggest that bio-degradation of the source area contaminant mass is occurring and ongoing at present.

- Three (3) of the nine (9) groundwater monitoring wells have now completed four (4) consecutive quarters of groundwater monitoring, in which contaminant concentrations have remained non-detect and/or below the Washington State Department of Ecology's target levels. These monitoring wells include MW-1, MW-4, and MW-8. With the completion of four (4) consecutive quarters of compliance at MW-1 and MW-8, it may be reasonable to infer that in regard to the "Bayview parcel" the lateral extent of the PCE groundwater plume appears to be limited to the northern most drive lane and does not appear to underflow the auto parts building or areas of the "Bayview" parcel further south.
- Although dissolved contaminant concentrations appear to generally be declining, the concentrations of PCE in groundwater at MW-6 and MW-7 over the past four (4) quarters demonstrate that a portion of the groundwater plume likely encroaches onto the Bank parcel. It remains unknown as to how far the "plume" has migrated along its longitudinal axis, or what portions of the Bank parcel may be impacted. As an additional consideration, from past historical research the Bank parcel appears to have historically been occupied by a gasoline service station, which may conceivably have contributed to environmental impairments on that parcel. At present, EAI is not aware of any prior environmental work performed on the Bank parcel. It is EAI's understanding that ownership of the Bank parcel desires Tri Western to expand site assessment activities onto their parcel. Additional discussions in that regard are included in the Recommendations Section below.

Recommendations

In recognition of the above summary of findings, the following recommendations are offered in moving forward:

- <u>Continue with quarterly groundwater monitoring</u>: EAI recommends continuing with regularly scheduled quarterly groundwater monitoring. Acknowledging that the wells were last sampled in late October 2012, the next proposed sampling event should be scheduled for late January 2013. In regard to monitoring wells MW-1, MW-4, and MW-8 which have all demonstrated four (4) consecutive quarters of "compliance" monitoring, it may be justifiable to reduce the sampling frequency of those wells to semi-annually (twice a year).
- Assessment of Current Environmental Conditions on the Bank Parcel. Further exploration on the Bank parcel is warranted in an effort to further resolve the lateral limit of the PCE plume. Additionally, EAI has been advised that the Bank property ownership has expressed a concern regarding indoor air environmental quality as it may relate to vapor intrusion. To begin to address the Bank property ownership's concerns, EAI recommends the following actions:

- Installation of approximately three (3) permanent groundwater monitoring wells to be positioned around the bank parcel to augment the existing network of monitoring wells.
- Prepare a proposed scope of work for evaluating potential indoor-air quality issues within the Bank building, beginning with soil vapor sampling.
- Request that bank property ownership provide copies of any prior environmental studies performed on or referencing their parcel, particularly since the bank parcel was reportedly historically occupied by a gasoline service station.
- Develop Feasibility Plan for Augmenting or Expanding Remediation Approach: In particular, as discussed with the Client during the recent December 20th 2012 meeting, if the January 2013 monitoring event demonstrates a return to typical groundwater elevation levels and contaminant concentrations have not resumed their prior rate of decline, EAI would then recommend implementing the feasibility study to evaluate potential additional remedial measures including the construction of one or more additional remediation "trenches" or a site-wide "grid" injection program. The feasibility study would essentially consist of completing a series of borings, across the study area. Recovered soil and groundwater samples would be used to estimate average "sorbed" and dissolved contaminant masses so that recommended volumes of remediation product could be calculated. Additionally, the collected contaminant mass data would be used to evaluate potential placements of additional interceptor/injector trenches, soil disposal options and cost projections.
- At a minimum, regardless of the concentration trend at the time of the January 2013
 monitoring event, EAI recommends reapplying remediation product to the existing
 infiltration trench, to ensure continued degradation of contaminant mass at the suspected
 source area.

Limitations

This report has been prepared specific application to this project in a manner consistent with that level of care and skill normally exercised by members of the environmental science profession currently practicing under similar conditions in the area. This document is for the exclusive of Tri Western Syndicated Investments, Inc., along with its members and appointed representatives. Commentary with respect to subsurface environmental conditions relies solely upon the results of sampling and testing conducted at separated sampling localities and environmental conditions may vary between those localities or at other locations, depths, and/or media. No other warranty, expressed or implied, is made here. If new information is acquired or developed in future site work Environmental Associates, Inc., must be retained to reevaluate the conclusions of this letter report and to provide amendments as required.

ENVIRONMENTAL CHEMISTS

James E. Bruya, Ph.D. Yelena Aravkina, M.S. Bradley T. Benson, B.S. Kurt Johnson, B.S. 3012 16th Avenue West Seattle, WA 98119-2029 TEL: (206) 285-8282 e-mail: fbi@isomedia.com

November 1, 2012

Rob Roe, Project Manager Environmental Associates, Inc. 1380 112th Ave. NE, 300 Bellevue, WA 98004

Dear Mr. Roe:

Included are the results from the testing of material submitted on October 26, 2012 from the Tri-Western/Mac's Cleaners JN-20209-5, F&BI 210478 project. There are 16 pages included in this report. Any samples that may remain are currently scheduled for disposal in 30 days. If you would like us to return your samples or arrange for long term storage at our offices, please contact us as soon as possible.

We appreciate this opportunity to be of service to you and hope you will call if you have any questions.

Sincerely,

FRIEDMAN & BRUYA, INC.

Michael Erdahl Project Manager

ENVIRONMENTAL CHEMISTS

CASE NARRATIVE

This case narrative encompasses samples received on October 26, 2012 by Friedman & Bruya, Inc. from the Environmental Associates Tri-Western/Mac's Cleaners JN-20209-5 project. Samples were logged in under the laboratory ID's listed below.

<u>Laboratory ID</u>	Environmental Associates
210478-01	MW-1
210478-02	MW-2
210478-03	MW-3
210478-04	MW-4
210478-05	MW-5
210478-06	MW-6
210478-07	MW-7
210478-08	MW-8
210478-09	MW-9
210478-10	Drum

Methylene chloride in the 8260C laboratory control sample and laboratory control sample duplicate exceeded the acceptance criteria. The analyte was not detected in the sample, therefore the data were acceptable.

All other quality control requirements were acceptable.

ENVIRONMENTAL CHEMISTS

Data Qualifiers & Definitions

- a The analyte was detected at a level less than five times the reporting limit. The RPD results may not provide reliable information on the variability of the analysis.
- A1 More than one compound of similar molecule structure was identified with equal probability.
- b The analyte was spiked at a level that was less than five times that present in the sample. Matrix spike recoveries may not be meaningful.
- ca The calibration results for this range fell outside of acceptance criteria. The value reported is an estimate.
- c The presence of the analyte indicated may be due to carryover from previous sample injections.
- d The sample was diluted. Detection limits may be raised due to dilution.
- ds The sample was diluted. Detection limits are raised due to dilution and surrogate recoveries may not be meaningful.
- dv Insufficient sample was available to achieve normal reporting limits and limits are raised accordingly.
- fb Analyte present in the blank and the sample.
- fc The compound is a common laboratory and field contaminant.
- hr The sample and duplicate were reextracted and reanalyzed. RPD results were still outside of control limits. The variability is attributed to sample inhomogeneity.
- ht Analysis performed outside the method or client-specified holding time requirement.
- ip Recovery fell outside of normal control limits. Compounds in the sample matrix interfered with the quantitation of the analyte.
- j The result is below normal reporting limits. The value reported is an estimate.
- ${\bf J}$ The internal standard associated with the analyte is out of control limits. The reported concentration is an estimate.
- jl The analyte result in the laboratory control sample is out of control limits. The reported concentration should be considered an estimate.
- jr The rpd result in laboratory control sample associated with the analyte is out of control limits. The reported concentration should be considered an estimate.
- js The surrogate associated with the analyte is out of control limits. The reported concentration should be considered an estimate.
- lc The presence of the compound indicated is likely due to laboratory contamination.
- L The reported concentration was generated from a library search.
- $\,$ nm The analyte was not detected in one or more of the duplicate analyses. Therefore, calculation of the RPD is not applicable.
- pc The sample was received in a container not approved by the method. The value reported should be considered an estimate.
- pr The sample was received with incorrect preservation. The value reported should be considered an estimate.
- ve Estimated concentration calculated for an analyte response above the valid instrument calibration range. A dilution is required to obtain an accurate quantification of the analyte.
- vo The value reported fell outside the control limits established for this analyte.
- x The sample chromatographic pattern does not resemble the fuel standard used for quantitation.
