1 INTRODUCTION

This report summarizes the remedial investigation (RI) and feasibility study (FS) conducted for Union Ridge Investment Company (URIC) for the property located at 122 N. Main Avenue in Ridgefield, Washington (the Property) (see Figure 1-1). The RI/FS was conducted in accordance with the requirements of the Model Toxics Control Act (MTCA) and the Agreed Order No. DE 6829 between the Washington State Department of Ecology (Ecology) and URIC (the Agreed Order). The RI work was consistent with the Remedial Action Work Plan (Maul Foster & Alongi, Inc. [MFA], 2010a) and subsequent work plans, including the Supplemental Soil Gas Sampling Work Plan (MFA, 2010b), the Supplemental Indoor Air Sampling Work Plan (MFA, 2012), and the Remedial Investigation Work Plan Addendum (MFA, 2014), all of which were reviewed and approved by Ecology.

Previous investigations indicated that volatile organic compounds (VOCs) are present on the Property and in groundwater beneath neighboring properties (the Site; see Figure 1-2). Historically, the Property was used by Park Laundry, which performed dry cleaning operations likely resulting in the release of tetrachloroethene (PCE).

1.1 Purpose and Objectives

The RI/FS was designed to meet the requirements of the Agreed Order and MTCA (Washington Administrative Code [WAC] 173-340) for performing an RI (which includes a risk assessment [RA]) and FS. The FS considers remedial technologies for mitigating Site conditions posing an unacceptable risk to human health or the environment, with a focus on presumptive remedies to the extent possible and appropriate. The FS also identifies final cleanup levels (CULs) for the Site.

Extensive soil, groundwater, soil gas, and air data have been collected at the Site since 2001. In 2014, Ecology determined that there were additional data gaps in order to complete the RI/FS (Ecology, 2014). The additional characterization work included:

- Slug testing to obtain site-specific estimates of hydraulic conductivity
- Additional soil and groundwater characterization to assess fate and transport of Site indicator hazardous substances (IHSs), which included PCE and its degradation products (including trichloroethene [TCE], cis-1,2-dichloroethene [DCE], trans-1,2-DCE, and vinyl chloride)
- Completion of an ecological receptor RA (terrestrial ecological evaluation [TEE])

2 BACKGROUND

2.1 Property and Site Description

The Property is zoned as Downtown Mixed Use and is approximately 25 feet wide (north-south) and 100 feet long (east-west). The Property is immediately adjoined by commercial businesses or publicly owned entities (e.g., police and fire station) (see Figure 2-1). Beyond these, the land use is primarily residential.

The Site is defined by the extent of Property-related contamination, which corresponds to the extent of groundwater contamination¹. The groundwater plume covers an estimated 22 acres. The plume generally follows the topography of the area, extending north and west from the Property, and is bounded on the west by Lake River. Soil impacts and, potentially, vapor intrusion or air impacts are within the extent of groundwater impacts (Site boundary; see Figure 1-2).

For the purposes of this report, “the Source Area” is defined as the area of the Site with the highest concentrations in soil, groundwater, and soil vapor; which includes the Property and the two vacant lots located directly north of the Park Laundry property, collectively (see Figure 1-2).

2.2 Site History

Historically, a building covered the western two-thirds of the Property. The building was constructed in approximately 1948 and removed in 2000. In the 1960s, an addition to the building, covering the entire Property, was constructed. Park Laundry used the building from approximately 1965 to 1977. The former owner/operator, Mr. Alvin Johnson, is deceased. The laundry service is believed to have included dry cleaning services and self-service, coin-operated washers and dryers.

Park Laundry’s operations had ceased by 1978; URIC purchased the Property on May 31, 1979. There was no dry-cleaning equipment in the building at the time of purchase. The Property was sold to Mr. Larry Beaman on February 15, 2000. Mr. Beaman removed the building and subsequently defaulted on his obligations. The Property was quitclaimed to Mr. Robert Hyatt, representing URIC, who then quitclaimed the Property to URIC on November 19, 2007.

A parking lot used by the Ridgefield Police Department and owned by the City of Ridgefield (the City) is located along the southern border of the Property. To the east is a one-lane, paved alleyway, bordered by a city skate park. To the west is North Main Avenue and a food and drink establishment owned by MRS Development, LLC. To the north are two vacant lots owned by Frankie Rima-Hinrichs (Clark County GIS, 2016).

MFA reviewed state and federal agency database records, aerial photographs, and Sanborn Fire Insurance Maps for historical information related to the Property to evaluate the area for other

¹ Defined as having an exceedance of the Model Toxics Control Act Method A cleanup level.

potential sources of contamination (MFA, 2011a). Based on MFA's review of state and federal agency records, petroleum-hydrocarbon contamination has been confirmed on nearby properties; however, it is not a chemical of interest at the Property. No other sources of PCE were identified.

2.3 Geology and Hydrogeology

2.3.1 Site Geology and Hydrogeology

Borings have been advanced to as deep as 80 feet below ground surface (bgs) on the Property. Borings downgradient of the Property have been advanced as deep as 90 feet bgs. Figure 2-2 shows the location of a geologic cross section through the Site. The generalized geologic cross section is shown on Figure 2-3.

The geology on the Property, and on the upper terrace generally, consists of fine and silty sand to a depth of 15 feet bgs. An aquitard, composed of clayey material, underlies the sand and silty sand. The depth to clay, and therefore the thickness of the surficial silty sand, increases to the north and west. Both the surficial silty sand unit and the clay unit are considered to be Pleistocene alluvium. The aquitard is unsaturated and the shallow groundwater is perched in the upper terrace.

On the Property and the upper terrace, the clay unit is approximately 40 feet thick, with the bottom approximately 55 to 60 feet bgs. The clayey layer was observed in the borings at shallower depths to the south and east. Underlying the clay unit is a silty gravel (the Upper Troutdale Formation). In monitoring wells north of the Property (MW17 and MW18), the bottom of the clay layer was encountered at 33 feet bgs and 42 feet bgs, respectively. At MW19, the monitoring well the farthest north from the Property, no significant clay layer was encountered; the lithology transitioned from the upper silty sand unit to the silty gravel (Upper Troutdale) at approximately 18 feet bgs. Therefore, it appears that the clay layer pinches out approximately 1,500 feet north of the Property.

The change in topography represents a facies change where the surficial silty sand unit and the clay units in the upper terrace (Pleistocene alluvium) are absent beneath the lower terrace of Lake River (west of Railroad Avenue, see Figure 2-1). On the lower terrace, at the nearby Port of Ridgefield (Port) and the adjacent boat launch parking area, four principal geologic units have been identified: fill, Holocene (younger) alluvium, Pleistocene (older) alluvium, and the Tertiary Upper Troutdale formation (see Figures 2-2 and 2-3).

The Port is west of, and approximately 50 feet lower in elevation than the Property. A portion of the Port, Cell 3, is part of the Site (see Figures 1-2 and 2-1). The silty gravel observed beneath the Pleistocene alluvium represents the top of the Troutdale Formation and, as a result of weathering, acts as an aquitard. Typically, the monitoring wells on Port property in which PCE has been detected are screened in the recent alluvium, approximately 40 to 50 feet bgs. Groundwater west of Railroad Avenue, beneath the Port property is considered potable. The use of groundwater on the Port's property is not allowed and there is a restrictive covenant that prevents the use of groundwater on the Port's property.

Groundwater east of Railroad Avenue is considered to be non-potable. The reasons for a determination of non-potability include:

- The groundwater in the upper terrace is not a current or future source of drinking water.
- Available groundwater in the upper terrace above the clay unit is shallow, thin with respect to saturated thickness, and the fine-grained nature of the sediments (surficial silty sand unit) result in low yields when pumped.
- The thin, shallow nature of the perched groundwater in the upper terrace precludes well installation that would meet the Washington minimal functional standards for a supply well.

In the upland terrace, PCE is detected primarily in the surficial silty sand unit (Pleistocene alluvium) overlying the clay aquitard. It appears that there is a connection between the silty sand unit in the uplands and the Pleistocene alluvium (sandy/silty gravel) unit on the lower terrace and beneath the Port (see Figure 2-3). Ecology determined that because contaminated groundwater from the non-potable portion of the Site migrates to groundwater that is potable (on the Port's property), groundwater throughout the Site is considered to be potable. Generally, groundwater has been observed in the sand and silty sand (Pleistocene alluvium) of the upper terrace at approximately 5 to 10 feet bgs, and this groundwater is referred to throughout this report as the upper water-bearing zone (WBZ), which overlies the clay aquitard. Groundwater below the clay aquitard in the Upper Troutdale unit is referred to throughout this report as the lower WBZ. The estimated groundwater flow direction in the upper WBZ generally conforms to topography (see Figures 2-4 and 2-5). The Property is located on the upper terrace, where groundwater flow varies from west to almost due north, forming a groundwater ridge. Groundwater contours mimic topography and become steeper to the west, with the gradient flattening on the lower floodplain terrace. Groundwater flows from the upper WBZ towards Lake River and the Port. Groundwater elevation data from Site monitoring wells show that groundwater flow to the west and north at the Site is consistent being the same season to season. Groundwater monitoring data on the Port's property in Cell 3 has shown that groundwater flow in the lower terrace is consistently to the west, toward Lake River.

2.3.2 Area Geology and Hydrogeology

Several municipal drinking wells are located in Abram's Park, northeast of the Property (also discussed in Section 5.4). Well logs from the city supply wells indicate geologic conditions in the shallow soils similar to those of the Property (Appendix A), with a clay layer beginning approximately 15 to 20 feet bgs. Below the clay is a sand and gravel unit beginning at approximately 40 feet bgs (which corresponds to approximately 10 feet bgs at the Port) which is approximately 30 to 40 feet thick. Although the clay layer is absent beneath the Port, based on similar soil descriptions, the sand and gravel unit farther east on the ridge is connected to the similar Pleistocene alluvium layer found under the Port and the boat launch parking area, and that the unit dips slightly toward the west.

2.4 Previous Investigations and Cleanup Actions

Previous site investigations have identified VOC impacts in soil and groundwater on the Site (refer to Figures 2-6 and 2-7 for sampling locations). Previous investigations include the following:

- In November 2001, on behalf of the Port, MFA conducted a Phase II environmental site assessment on the 204-206 North Main Avenue property, north of the Property. MFA completed three borings (GP-1 through GP-3) and analyzed groundwater samples for VOCs. Detections of PCE in the three borings were above Ecology MTCA Method A screening levels (MFA, 2001).
- In July 2006, Hahn and Associates, Inc. (Hahn) conducted a subsurface investigation on the parcel directly north of the Property. Hahn completed five borings and conducted analysis for VOCs on groundwater samples from four of the borings (B-1 through B-4) (Hahn, 2006). PCE detections in all four borings were above MTCA Method A screening levels.
- In October 2006, Clark County Public Health's Environmental Health Division (Clark County Health) completed six borings (PL1 through PL6) on and directly north of the Property to collect soil and groundwater samples (Clark County Health, 2006). Soil samples were collected from the saturated zone, and groundwater samples were collected in the upper WBZ. The samples were analyzed for VOCs. Concentrations of PCE in soil exceeded MTCA Method A screening level values in PL2, PL3, and PL5. PCE in groundwater exceeded MTCA Method A in PL2 through PL5. The investigation conducted by Clark County Health led Ecology to place the Property in the Confirmed and Suspected Contaminated Sites database on January 4, 2007 (Clark County Health, 2006).
- In April 2008, the U.S. Environmental Protection Agency (USEPA) and its contractor, Ecology and Environment, Inc. (E&E), conducted testing from 24 borings (BG01 and GP01 through GP23) on and near the Property (E&E, 2008). Soil was collected from the saturated zone and from the vadose zone directly above groundwater from borings BG01 and GP01 through GP15 and subsequently analyzed. Groundwater samples were collected from all 24 borings in the upper WBZ and analyzed. Chlorinated solvents were detected on and near the Property above MTCA Method A screening levels (soil from borings GP02, GP07, GP08, GP11, and GP14; and groundwater from GP02 through GP08, GP11 through GP17, and GP19) (E&E, 2008).

Tables 2-1 through 2-3 summarize analytical results for VOCs in soil and groundwater from these investigations. Table 2-3 also contains groundwater data from monitoring wells in Cell 3 at the port (MFA, 2016).

In addition to historical investigations conducted on the Property, in the Source Area, and the immediate vicinity, detections of PCE in groundwater have been noted at the port's Cell 3 (see Figure 2-1) approximately 700 feet west and downgradient of the Property. The data for Cell 3 can be found in the February 2007 Cell 3 Remedial Investigation and Risk Assessment Report (MFA, 2007), and relevant data are included in this report (Table 2-3). PCE was detected in monitoring wells completed in the port's deeper portion of the upper WBZ (the Pleistocene alluvium; see Figure 2-3).

Based on the groundwater flow direction toward Lake River, the interconnectivity of the area geology, and groundwater sampling results, PCE observed in the deeper portion of the upper WBZ on Cell 3 and the boat launch parking area is the result of former Park Laundry dry cleaning operations.

Following extensive discussions with Ecology regarding the approach to assessing the potential for groundwater to impact Lake River and receipt of approval of this approach by Ecology, MFA performed additional characterization designed to assess if groundwater with concentrations of indicator hazardous substances (IHSs) would or would not be expected to impact Lake River or groundwater beneath the Ridgefield National Wildlife Refuge. At Ecology's direction, the additional site-characterization work included:

- Slug testing to obtain site-specific estimates of hydraulic conductivity.
- Sediment sampling to obtain organic carbon values for Lake River sediment.
- Conservative groundwater fate and transport modeling.
- Groundwater characterization across Lake River and west of Cell 3 on the Ridgefield national Wildlife Refuge.

Conservative groundwater modeling showed that IHSs would not reach Lake River (MFA, 2007). At Ecology's direction, the 2007 BIOCHLOR groundwater model conservatively assumed that no reductive dechlorination of PCE was occurring, and modeled attenuation of PCE based only on dispersion, adsorption, and first order decay. Both 30- and 100-year model runs indicated that PCE concentrations in groundwater would attenuate to levels below the most stringent regulatory criteria (surface-water CULs) before discharging to Lake River. Based on these modeling efforts, it is unlikely that groundwater discharges to Lake River will pose unacceptable risks to receptors. Groundwater sampling on the Ridgefield National Wildlife Refuge, performed at the direction of Ecology also showed that groundwater impacts from Cell 3 had not impacted groundwater beneath the refuge. Therefore, CULs for groundwater protective of surface water were not considered to be appropriate.

3 FIELD AND ANALYTICAL METHODS

Historical investigations of the Site were conducted by the Clark County Health Department and Hahn in 2006 and by the USEPA in 2008. MFA's RI activities began in 2010, with an investigation characterizing soil, groundwater, and soil vapor. Initial results did not fully define the extent of contamination, and further investigations were completed for both soil and groundwater. Groundwater results in relation to local homes and businesses indicated the possibility of vapor intrusion, supporting the need for a vapor intrusion investigation. MFA installed monitoring wells between 2011 and 2013. All the groundwater monitoring wells have been sampled quarterly since they were installed to provide representative analytical data; however, selected wells were sampled at a reduced frequency, as sample results indicated that concentrations have stabilized in those wells over time (see Table 3-1 for the monitoring schedule).

3.1 Soil

A summary of soil sample identification, depth, date collected, and analyses conducted is presented in Tables 3-2 and 3-3. In 2010, MFA advanced borings GP24 through GP61 from ground surface to the base of the surficial silt/sand unit, as well as advancing borings B5, and B8 through B11 below the

clay unit to the next encountered WBZ (the Site's lower WBZ) to assess potential impacts (see Figure 2-2). Bentonite seals were set in the clay unit, and step-down casing was used to advance the borings below the clay unit to prevent migration of contamination through the clay to the underlying lower WBZ. Borings B6 and B7 were advanced in 2010, concurrent with the other B-series borings, but only to the upper portion of the clay unit. For all boring locations described above, soil samples were collected at the surface (0 to 0.5 foot bgs), directly above the water table (5 feet bgs), and colocated with groundwater sample depths. Boring logs are provided in Appendix B. Field sampling data sheets are included as Appendix C. Laboratory reports and data validation memoranda can be found in Appendix D and Appendix E, respectively.

Samples from each boring were selected for analysis, based on observed impacts, elevated head-space readings collected with a photoionization detector, and/or information from previous investigations regarding detections of PCE. During the initial reconnaissance sampling event in March 2010, soil and groundwater samples were analyzed for VOCs by USEPA Method 8260B. There were a few random detections of VOCs, but other than PCE and other breakdown products, there were none at levels of concern, and it was then determined that PCE and breakdown products were the IHSs for the Site (Table 3-2). Subsequent soil samples were analyzed for halogenated VOCs by USEPA Method 8260B with USEPA Method 5035 sample preparation.

Borings GP62 through GP81 were advanced during MFA investigations in 2011. These borings were downgradient of the Property (see Figure 2-2). Because of the limited spatial extent of soil impacts observed in GP24 through GP61, no soil samples were collected at these locations.

In 2014, at the direction of Ecology, MFA advanced four additional borings (GP82 through GP86) and soil was sampled for chemical oxygen demand and total organic carbon. See Figure 2-2 for sampling locations and Table 3-4 for sample results.

3.2 Groundwater

3.2.1 Reconnaissance Samples

MFA collected upper WBZ groundwater samples from reconnaissance borings GP24 through GP81 and from B5 through B11 to help define the lateral extent of PCE impacts to shallow groundwater in the surficial unit. In addition, shallow groundwater samples proximal to nearby buildings provided data used in the vapor intrusion preliminary assessment. A summary of reconnaissance sample identification, depths, dates of collection, and analyses is presented in Tables 3-5 and 3-6.

Groundwater samples collected in the lower WBZ included B9-W-75.0, B9-W-89.0, B10-W-57.0, and B11-W-88.0. These borings were located on and downgradient of the Property (see Figures 2-2 and 2-3). Multiple groundwater samples were collected in the lower WBZ at location B9, the location where the lower WBZ was observed to be thickest (see Figure 2-3).

As with soil, during the March 2010 sampling event, groundwater was analyzed for VOCs by USEPA Method 8260B. From that event, it was confirmed that PCE and breakdown products were the IHSs in groundwater for the Site (Table 3-5). Subsequent groundwater samples were analyzed by USEPA Method 8260B for the focused VOC list of halogenated compounds shown on Table 3-6. This allowed

the laboratory to reach lower reporting limits, down to the detection limit (1 part per billion) for the targeted IHSs. The rationale for selecting these compounds was the historical use of the Property as a dry cleaner and the fact that PCE and associated breakdown products are the only contaminants of concern.

3.2.2 Monitoring Wells

At Ecology's request, MFA began quarterly groundwater sampling at the Site in March 2012. Monitoring wells were installed based on the estimated groundwater flow direction, PCE concentrations in reconnaissance borings, and distance from the presumed source area. Data from each monitoring event were submitted to Ecology in letter format. Groundwater sampling and analysis focused on the evaluation of PCE and its potential degradation products (primarily TCE, cis-1,2-DCE, trans-1,2-DCE, and vinyl chloride) above MTCA CULs.

In October 2012, at the request of Ecology, monitoring well groundwater samples were analyzed by USEPA Method 8260 for the full list of VOCs, but no other Site IHSs were identified. Field sampling data sheets are included as Appendix C. Laboratory reports and data validation memoranda can be found in Appendix D and Appendix E, respectively. Depth-to-groundwater measurements were recorded during each monitoring event and are shown on Table 3-7.

3.2.3 Aquifer Testing

In December 2014, at the direction of Ecology, slug testing was conducted at six monitoring wells (MW01, MW03, MW04, MW08, MW15, and MW16) to determine the hydraulic conductivity and transmissivity of the upper WBZ on the upland terrace, as well as in the transition zone going down the hill and on the lower terrace near the river. These parameters were used in the evaluation of contaminant fate and transport and an assessment of the capacity for the upper WBZ to produce potable water. The methods used for the pneumatic slug testing followed the detailed standard operating procedure (SOP) included in Appendix F; in general, the procedure involved the following steps:

- Installation and calibration of a data logger (transducer) in the well
- Pressurizing the air column above the standing water to force groundwater out of the well screen and into the formation
- Releasing the pressure and recording the rise in head, using the transducer
- Analysis of the rising head data, using AquiferTest Pro 2014

The pneumatic slug testing equipment (transducer, laptop, connections, and pump or gas cylinder) was supplied by the subcontractor (Cascade Drilling of Clackamas, Oregon). MFA analyzed the data, using AquiferTest Pro 2014 (see Appendix F), which allows for analysis using standard methods (e.g., American Society for Testing and Materials) that are consistent with those described in Kruseman and de Ridder (1994).

3.3 Air

MFA conducted initial soil gas sampling in March 2010 and June 2011 (MFA, 2010c; 2011b). These samples were collected on the Property, as well as to the south and north, and analyzed for PCE and breakdown products (1,1-DCE, cis-1,2-DCE, trans-1,2-DCE, TCE, and vinyl chloride). See Figure 3-1 for sample locations and sample results for PCE. Several locations had PCE detections above the MTCA Method B soil gas screening levels, indicating that a follow up vapor intrusion exposure assessment was warranted to assess the likelihood of vapor intrusion into homes and businesses in the area.

As recommended in Ecology's draft vapor intrusion guidance (Ecology, 2009b), the vapor intrusion exposure assessment was conducted using a tiered approach consisting of a preliminary assessment, a Tier I assessment, and a Tier II assessment. A vapor intrusion and soil gas study area (see Appendix G) was designated based on results of the initial soil gas sampling and reconnaissance groundwater samples (see Tables 3-5 and 3-6).

Both Ecology and the Washington State Department of Health concluded that the indoor air pathway was not a complete exposure pathway and no further assessment or remediation for potential impacts to indoor air were necessary.

3.3.1 Preliminary Assessment

The goal of the preliminary assessment was to determine if there was potential for vapor intrusion into a property or residence. Previous site investigations identified VOC impacts in the soil, groundwater and soil gas near occupied buildings; this justified continuing with a Tier I assessment (Clark County Health, 2006; E&E, 2008; Hahn, 2006; MFA, 2001, 2011c).

3.3.2 Tier I Assessment

The Tier I assessment conducted in fall 2012 through summer 2013 included collecting data to define the nature and extent of contamination in the subsurface and developing preliminary conceptual site models (CSMs) for each building on or within 100 feet of the groundwater plume to identify locations with the greatest potential for vapor intrusion. Subsurface characterization was accomplished using soil and groundwater samples described above to define the nature and extent of shallow subsurface contamination. The results of the soil and groundwater investigation were used to define a vapor intrusion study area, which includes properties directly above or within 100 feet of the groundwater plume boundary (Figure 3-2).

MFA developed preliminary CSMs, based on information from written building surveys issued to occupants by Ecology and on information gathered from a property visit (which consisted of observing each of the properties in the vapor intrusion study area from adjacent public rights-of-way). The purposes of the CSMs (see Appendix C of Appendix G for CSM figures) were to identify possible exposure pathways as well as to prioritize buildings for sampling in order to assess the potential for vapor intrusion. Buildings were selected for Tier II assessment - indoor air sampling, based on factors such as proximity to the groundwater plume, the individual property owner's permission to conduct

the assessment, building construction type, and identification of exposure pathways, such as foundation cracks and utility penetrations. Three vacant properties were also included in the Tier II sampling assessment to evaluate the probability that indoor air could be impacted should a building be constructed there in the future.

3.3.3 Tier II Assessment—Vapor Intrusion Sampling

For the Tier II Assessment, 48 samples were collected and analyzed in 2012, and 47 during the 2013 field activities including indoor air samples, crawlspace air samples, soil gas samples, sub-slab soil gas samples, and background outdoor air samples. The sampling scope for properties in the vapor intrusion study area is summarized in Table 3-8. Soil gas and background outdoor air sampling locations are shown on Figure 3-3. In addition, property-specific indoor air and sub-slab sample locations are shown on each building CSM (see Appendix G).

The preliminary site visit included occupant interviews, an inspection to identify sampling locations, and the removal of potential indoor sources of chlorinated VOCs. To aid in the identification of potential indoor sources of chlorinated VOCs, MFA used a portable gas chromatograph/mass spectrometer, consistent with manufacturer-provided instructions, to screen the indoor air in each building during the preliminary site visits. Identified sources of possible chlorinated VOCs were removed until sample collection was completed.

Generally, criteria for selecting indoor air/crawlspace sample locations included the following:

- An attempt was made to collect at least one sample from each floor that contained occupied areas, including basements.
- For residences, sampling points focused on primary living areas and locations that may be most susceptible to subsurface vapor entry (e.g., utility penetrations, ventilation, bathrooms, and kitchens).
- For commercial buildings, samples were collected from primary work areas, as well as near identified points of vapor entry (e.g., sumps, utility line openings, and floor drains).
- The number of samples collected was generally consistent with professional judgment and the New Jersey vapor intrusion technical guidance document (Attachment 1 of Appendix G).
- If there was a crawlspace beneath the building, an attempt was made to collect at least one sample from the crawlspace. If feasible, the crawlspace sampling location was situated near the center of the building, away from vents or crawlspace openings.

Generally, criteria for selecting sub-slab sample locations included the following:

- Sub-slab samples were not collected from locations that contact or that reasonably could come into contact with groundwater or the capillary zone.

- Generally, basements on the Park Laundry site were not selected for sub-slab sampling. Exceptions were considered at the request of Ecology, based on a site-specific assessment of the potential for the slab to come into contact with water.
- The number of samples collected was generally consistent with professional judgment and the New Jersey vapor intrusion technical guidance document (Attachment 1 of Appendix G).
- Generally, sample probes were located near the center of the slab and were equidistant from each other relative to the outer walls of the building.
- If different slab materials were present, at least one sample was collected from each different type of slab material.

Sub-slab and/or soil gas sampling ports, if applicable, were installed during the preliminary visit. Preliminary visit field notes, observations, and occupant interviews, which aided in determining sample locations, are summarized in Appendix B of Appendix G of this report.

Samples were collected, consistent with the work plan, approximately 24 hours after the preliminary visit and according to the following methods:

- Indoor/crawlspace air samples. Indoor air samples were collected from each level (basement, first floor, second floor, etc.) and the crawlspace, if applicable, of each building included in the assessment. Sampling was conducted by MFA field staff, with oversight provided by an MFA certified industrial hygienist. The samples were collected in pre-evacuated, 6-liter, stainless steel canisters (Summa© canisters) with 24-hour flow controllers. Indoor air samples were collected 3 to 5 feet above the floor, and crawlspace samples were collected directly on the ground. Sampling criteria for indoor/crawlspace air samples are included in Attachment 1 of Appendix G.
- Sub-slab soil gas samples. Sub-slab soil gas samples were collected from the space immediately below the slab-on-grade or basement floor slabs, using permanent sampling points. Sub-slab holes were advanced through the concrete floor of each foundation slab and 3 to 4 inches into the engineered fill below the slab. Vapor probes were installed and sealed in each concrete slab, and connected to 1-liter Summa canisters used to collect the samples. Helium was contained around the sampling apparatus and sampling probe to serve as a leak-check compound during sampling. A detailed SOP describing the sub-slab soil gas sample collection procedure is included in Attachment 2 of Appendix G.
- Soil gas samples. Soil gas borings were advanced using a Geoprobe™ direct-push drilling unit. In-ground vapor probes, each consisting of a 0.5-inch-outside diameter pipe, with 6-inch long stainless steel screen, were connected to Teflon tubing. Each sample tube was pushed to a depth of approximately 5 feet bgs. For sampling the tubing was connected to 1-liter Summa canisters. Helium was contained around the sampling apparatus and sampling tubing to serve as a leak-check compound during sampling. A detailed SOP describing the soil gas sample collection procedure is included in Attachment 3 of Appendix G.

- Outdoor air samples. MFA collected outdoor air samples from three separate locations outside the groundwater plume boundary. Wind-direction data was collected to determine which outdoor air sampling point was in an upwind location during sampling. Outdoor air samples were collected at the same time as indoor air samples were collected. MFA placed 6-liter, stainless steel canisters (Summa canisters), each with a 24-hour flow controller, to the north, east, and south of the groundwater plume boundary. Wind-direction data were collected with a portable weather station mounted on the roof of the hardware store in downtown Ridgefield (on the corner of Pioneer Street and North Main Avenue).

Wind roses used to evaluate wind patterns for the selection of background sampling locations are included in Appendix A of Appendix G.

Samples from the above-referenced areas were analyzed for PCE and associated breakdown products (TCE; 1,1-DCE; cis-1,2-DCE; trans-1,2-DCE; 1,1-dichloroethane [1,1-DCA]; 1,2-DCA; chloroethane; and vinyl chloride) by Modified USEPA Method TO-15 selective ion monitoring.

4 NATURE AND EXTENT

The nature and extent of IHSs have been delineated in soil, groundwater, and air by a number of investigations. PCE and breakdown products are IHSs in each medium discussed. For a more detailed discussion of CULs used and specific exceedances, refer to Section 6.

4.1 Soil

Soil investigations were conducted in 2010 and 2011 to delineate the nature and extent of soil impacts (MFA, 2010c; 2011a,b).

Soil was sampled at the surface (0 to 0.5 foot bgs), directly above the water table (5 feet bgs), and collocated with groundwater sampling at depth. Beneath the Property and in the immediate vicinity, concentrations of PCE at 5 feet bgs generally correspond to those at the surface, but are most often at slightly lower concentrations (see Tables 3-2 and 3-3), indicating that contamination likely originated from the surface. Elevated concentrations of PCE in soil below the water table correlate to elevated concentrations in groundwater (see Section 4.2) beneath the Property and the Source Area. As shown in Figure 4-1, the extent of the soil impacts as deep as 15 feet bgs are generally confined to the eastern end of the Property and the adjacent properties to the south and north (which corresponds to an area directly behind the former Park Laundry building). However, there was one soil exceedance of MTCA Method A criteria beyond the eastern end of the Property in the upper 15 feet (at 14.5 feet) in location B8 (located in the Source Area).

Additional soil samples were collected from the top one to two feet of the upper confining clay unit in some deeper borings (B5, B7, B8, and B9) to assess the possibility of migration of PCE into the clay unit (see Table 3-3). The highest PCE concentrations in the top one to two feet of the clay unit are from borings B5 and B8 (samples B5-S-14.0 and B8-S-16.5) were detected at concentrations of

1,800 and 4,370 micrograms per kilogram (ug/kg), respectively. Lower PCE concentration levels in the top two feet of the clay unit were found in borings B7 and B9 (samples B7-S-15.5 and B9-S-21.5) at 351 and 507 ug/kg, respectively. Concentration levels of PCE from samples collected deeper in the clay unit, i.e., approximately 22 to 27 feet (B5-S-39.0, B8-S-40.0, B9-S-42.0) from the top of the clay unit, were below method reporting limits. Groundwater was not present in the clay unit. Groundwater was found below the clay unit at approximately 80 feet bgs in the sandy gravel unit of the Upper Troutdale Formation.

4.2 Groundwater

In order to fully quantify the nature and extent of groundwater impacts, MFA has conducted the following: reconnaissance sampling, monitoring well sampling, aquifer testing, and a natural attenuation analysis.

4.2.1 Reconnaissance Groundwater Samples

Results from reconnaissance groundwater samples were used to preliminarily identify IHSs and begin to characterize the nature and extent of groundwater contamination. Monitoring wells were subsequently installed to provide better quality data for characterizing the nature and extent of groundwater impacts. Results are shown in Tables 3-5 and 3-6, and locations in Figure 2-2.

PCE detections in the upper WBZ indicate that the highest concentration of PCE is on the eastern side of the Property, similar to the results of the soil sampling. The highest detection of PCE was at GP52, at a concentration of 37,700 micrograms per liter (ug/L) (see Figure 2-2 and Table 3-6). Concentrations of this magnitude have not been replicated in groundwater collected from monitoring wells on the Site. However, in addition to GP52, three historical borings on and directly adjacent to the east side of the Property (GP02, GP08, PL3; see Figure 2-7 and Table 2-3) have had concentrations of PCE elevated by a magnitude similar to that of GP52.

The extent of groundwater contamination south, southeast, and northeast of the Property is defined by a series of borings with IHS detections below CULs: GP24 through GP29, GP36, GP70, and GP78 (see Table 3-6). Downgradient of the Property, a relatively high concentration of PCE (2,600 ug/L) was detected in groundwater (the upper WBZ) at B8. Soil samples collected from B8 between 0 and 5 feet bgs contained PCE concentrations below MTCA screening levels (see Table 3-3 and Figure 4-1), which indicates that the elevated levels of PCE in groundwater at this location are the result of groundwater migration, rather than a secondary surficial source of PCE.

Borings B8 through B11 were advanced to evaluate the vertical extent of contamination beneath the upper terrace Pleistocene alluvium clay unit and the Upper Troutdale silty gravel aquitard units. While some of the samples were damp, saturated conditions were not encountered.

B8 was advanced to a total depth of 80 feet bgs and terminated in the Upper Troutdale silty gravel aquitard. B9 and B11 were advanced to depths of 94 and 100 feet, respectively, and both encountered groundwater in the Upper Troutdale sandy gravel (lower WBZ). Boring B10 was advanced to a total depth of 69.5 feet bgs, and terminated in the Upper Troutdale silty gravel aquitard. The clay aquitard was not observed in B10. Groundwater was observed in a lens of sandy alluvial material in the interior

of the silty gravel aquitard (see Figure 2-3). With the exception of this lens of sandy alluvial material, saturated conditions were not observed in either the Pleistocene alluvium clay or the Upper Troutdale silty gravel aquitards. The maximum PCE concentration observed in groundwater samples collected from the lower WBZ is 5.46 ug/L (see Table 3-6). However it is possible that concentrations detected in the lower WBZ during reconnaissance drilling were from drag-down of contamination from the upper WBZ, as the upper aquifer units were not cased off during drilling. Based on the thickness of the clay layer, the lack of groundwater in and below it, and the low concentrations in deeper groundwater, it does not appear that PCE has migrated vertically into the lower WBZ. MFA does not believe monitoring in deeper groundwater is warranted.

4.2.2 Quarterly Monitoring Well Sampling

Based on reconnaissance groundwater data, vertical extent of contamination is limited to the upper WBZ in the Pleistocene alluvium sand unit of the upper terrace and the hydraulically connected Pleistocene alluvium sandy gravel unit of the lower terrace². Monitoring wells were installed throughout the Site, targeting the upper WBZ in those units (see well completion details in Table 4-1). Twenty groundwater monitoring wells have been installed to enable complete characterization of the extent of groundwater contamination at the Site. Quarterly groundwater monitoring events were initially conducted beginning in March 2012, with a reduced monitoring frequency once concentration trends were established. Locations of the Park Laundry monitoring wells are included on Figures 1-2 and 2-2. Port monitoring wells are also included on both figures for informational purposes. Monitoring well analytical data are summarized in Table 4-2. Water quality parameter data are summarized in Table 4-3.

Groundwater sampling and analysis at the Site continue to focus on the characterization of IHSs, established during reconnaissance sampling as PCE and its possible degradation products (e.g., TCE, cis-1,2-DCE, trans-1,2-DCE, and vinyl chloride). TCE correlation to the PCE groundwater contamination is discussed in Section 4.2.4.

The highest concentrations of PCE in groundwater have consistently been measured in samples from MW03, north of the Property and within the Source Area, and MW05 (see Table 4-2). While earlier reconnaissance data indicated the presence of elevated concentrations of PCE on the Property (37,700 ug/L at GP52; see Table 3-6), data from monitoring well MW01 has been significantly lower than in MW03 and MW05, although there have been occasional exceedances of Method A CULs. And more recent results from MW02, show groundwater levels consistently below Method A CULs. MW01 was installed at the same sampling location as GP52. Both MW01 and MW02 are installed on the Property.

Figure 4-2 shows the concentration distribution of PCE and/or TCE for the September 2016 sampling event. Contaminant distribution has been generally consistent throughout monitoring events, and therefore this figure represents the extent of PCE/TCE concentrations at the Site. Generally speaking, PCE concentrations are highest in the Source Area. The PCE plume in groundwater follows groundwater flow direction, north-northwest. Concentrations decrease with distance from the Property in this north-northwest direction and are non-detect in wells MW17,

² Low-level detections in reconnaissance lower WBZ groundwater are likely due to drag-down of contamination during drilling.

MW18, and MW19. South and west of the Property, the plume is bounded by monitoring wells MW20 and MW8 (Figures 1-2 and 4-2).

TCE is detected in only some of the monitoring wells (consistently in MW6, MW9, MW10, MW11, and MW13). None of the other, subsequent, breakdown products (i.e., cis-1,2-DCE/trans-1,2-DCE, and vinyl chloride) are detected in any of the monitoring wells. These data suggest that PCE degradation is not occurring at the Site at a significant rate.

Trend plots for PCE in groundwater, included in Appendices H and I, demonstrate contaminant concentration fluctuations since March 2012. Most wells continue to show stability (i.e., concentrations not increasing or decreasing), with minor fluctuations in PCE concentrations. Six wells (MW02, MW06, MW08, MW17, MW18, and MW19) appear to be stable (i.e., remain below CULs). The remaining 14 wells are above CULs but show relative stability in PCE concentrations (concentration trends not increasing or decreasing).

4.2.3 Aquifer Testing

Information about aquifer characteristics was required in order to evaluate contaminant fate and transport in groundwater. MFA completed pneumatic slug testing in six of the monitoring wells as part of the RI requirements. Wells were chosen based on their location relative to the source area and the geologic unit in which they are screened to discern the difference in hydraulic conductivity between the various geologic units beneath the Site. Two of the wells that underwent the slug test are within and adjacent to the Source Area (MW01 and MW04) and are completed in the shallow Pleistocene alluvium silty-sand unit of the upper terrace; two wells (MW15 and MW16) are to the west of the Property in the transition zone between the Pleistocene alluvium of the upper terrace and the lower terrace and are completed in the Pleistocene sandy-gravel unit; and one well is on the lower terrace, closer to Lake River (MW08), and is completed in the Pleistocene sandy gravel unit. While the geologic units change as the transition occurs from the upper terrace of the Site to the lower terrace, all Site wells are screened in the upper WBZ.

The pneumatic slug tests were conducted on December 5 and 8, 2014. Raw data and hydraulic conductivity data are included in Appendix F.

The average hydraulic conductivities were calculated using data produced by the Bouwer & Rice modeling technique with AquiferTest Pro 2014. The Bouwer & Rice method is intended for unconfined aquifers. The Hvorslev method can also be extended to unconfined aquifers, but is more appropriate when the water table is not close to the top of the well screen. Both methods were used, and calculated values are included in Table F-1; however, because the top of screen is in fact close to the water table in the upper terrace wells (MW01 and MW03), the Bouwer & Rice values were deemed more appropriate and are discussed below.

Monitoring wells on the upper terrace and screened in the silty-sand upper WBZ (MW01, MW03, and MW04) had an average hydraulic conductivity (K) of 0.68 foot per day, while the lower monitoring wells screened in the sandy-gravel unit of the upper WBZ (MW15, MW16, and MW08) had an average hydraulic conductivity of 3.41 feet per day.

In order to evaluate whether the uppermost aquifer at the Site should be considered as a future source of drinking water, MFA estimated aquifer yield using hydraulic conductivity data from the slug testing (Table F-1, Appendix F). Transmissivity (T) was calculated using the relationship $T=bK$, with b defined as aquifer thickness. Once a value for T was known, aquifer yield was calculated using the relationship $T=1500 Q/s$, with Q defined as the yield and s as the drawdown. To find the maximum yield Q, it was assumed that s = aquifer thickness. Yield calculations for monitoring wells on the ridge and screened in the silty-sand unit of the upper WBZ (MW01, MW03, and MW04) ranged from 0.21 gallon per minute (gpm) to 0.43 gpm, with an average of 0.3 gpm, while the monitoring wells screened in the sandy-gravel unit (MW08, MW15, and MW16) had an average yield of 22.73 gpm across the unit. According to WAC 173-340-720(2)(i), groundwater is not a potential future source of drinking water if groundwater is present in insufficient quantity to sustainably yield more than 0.5 gpm. Based on this analysis, groundwater of the upper WBZ on the upper terrace beneath the Source Area and immediately downgradient fits the definition of nonpotable (MTCA 173-340-720(2)).

4.2.4 Natural Attenuation Analysis

The natural attenuation analysis was conducted to characterize the plume and how it has changed at the Site over the duration of water quality monitoring. As mentioned above, monitoring began in March 2012. The objective of the analysis is to identify natural processes (such as degradation and dispersion) that reduce concentrations of PCE and its degradation products (such as TCE). The analysis consisted of:

- Developing normalized trend plots to evaluate potential degradation
- Calculating attenuation rates for comparison to literature half-life values
- Screening data, using the USEPA Technical Protocol for Evaluating Natural Attenuation of Chlorinated Solvents in Groundwater (USEPA, 1998)

Normalized trend plots illustrate the minimal change in concentrations over time (see Appendix D). The normalized plots show the concentration over time as a ratio to the initial concentration in order to allow comparison of data between wells with different concentration levels. Although there is slight indication of decreasing PCE concentrations in MW01 and MW05, the normalized trend plots for all the wells indicate a generally stable plume. That is, while seasonal variations are evident, there are no significant increases or decreases indicative of degradation processes such as dechlorination.

Attenuation rates were calculated for the December 2014 and March 2015 events, using PCE concentration data from monitoring wells MW03, MW05, MW11, and MW13. The attenuation rate (k) was calculated by first plotting the natural log of the concentration vs. distance from the source (in this case, the source is MW03, where concentrations of PCE in groundwater have consistently been the highest).

Groundwater seepage velocities (V_{GW}) were calculated using the following equation:

$$V_{GW} = \frac{(K)(i)}{n_e}$$

The rate is then calculated as the product of the slope of the data plot and groundwater seepage velocity (USEPA, 2002) (see Appendix J):

$$\text{slope} = \frac{k}{V_{GW}}$$

Hydraulic conductivity (K) values were taken from the plume aquifer testing³ (Section 4.2.3). Hydraulic gradients (i) were developed using the December 2014 and March 2015 events between monitoring wells MW03 and MW11.⁴ For the purposes of this evaluation, effective porosity (n_e) was assumed to be 30 percent (representative of a typical silty sand). The attenuation rate (k, units are per day or day⁻¹) is transformed to half-life ($t_{1/2}$, days) using the equation $t_{1/2} = (0.693)/(k)$. Calculations resulted in attenuation half-life values for PCE that are longer than typical PCE half-life values, indicating that other processes (such as reductive dechlorination, the primary degradation process for chlorinated solvents) are not occurring to a significant extent.

The attenuation values (Appendix J) and normalized trend plot illustrations (Appendix I) support the conclusion that the plume is fairly stable. Absent dechlorination, the primary process reducing concentrations over distance is mechanical dispersion.

Finally, an analysis was conducted to assess the likelihood that natural attenuation is occurring in the existing PCE plume. The USEPA's Technical Protocol for Evaluating Natural Attenuation of Chlorinated Solvents in Ground Water (USEPA, 1998) identifies a process for ranking the relative strength of evidence that anaerobic biodegradation (i.e., dechlorination) is occurring, based on aquifer conditions and chemical concentrations. The evaluation focuses on concentrations of the following analytes:

- Dissolved oxygen
- Nitrate
- Ferrous iron
- Sulfate
- Sulfide
- Methane
- Redox potential
- pH
- Total organic carbon
- Temperature
- Carbon dioxide
- Alkalinity
- Chloride

³ The high-end K value in Appendix J was calculated by taking the average K values on Table F-1 for monitoring wells MW1, MW-3, and MW4; the low-end K value was the average from monitoring wells MW15 and MW16.

⁴ MW03 was selected because it has the highest PCE concentrations, and MW11 was selected because it is immediately downgradient in the path of the groundwater plume.

- Ethene

Site-specific concentrations of these parameters are compared to fixed criteria (identified in the Technical Protocol [USEPA, 1998]). The extent to which the parameter values differ from target values (which indicate ideal conditions for anaerobic degradation) is a qualitative measure of the potential for naturally occurring attenuation (via anaerobic dechlorination) of chlorinated compounds.

MFA collected samples from selected monitoring wells at the Site and analyzed the samples for the natural attenuation parameters identified above (see Appendix J). The data were evaluated consistent with the Technical Protocol (USEPA, 1998). The samples from the Site scored low, indicating less than ideal conditions for anaerobic dechlorination. These results, combined with the relative absence of TCE and degradation products, provide little if any evidence that natural attenuation by anaerobic dechlorination is occurring (see Appendix J).

4.3 Air

MFA conducted a soil gas and vapor intrusion assessment over the course of three sampling events, from 2010 to 2013. The assessment encompassed potential impacts in soil gas, sub-slab, and indoor/outdoor environments (see Figure 3-2 for study area). Initial soil gas sampling was conducted in 2010 and 2011. See Figure 3-1 for sampling locations and Table 4-4 for sampling results. PCE concentrations in soil gas in the Source Area were high enough to indicate that, should a building be constructed on those properties, vapor intrusion would be a concern. The presence of PCE warranted consideration of possible vapor intrusion into other buildings on the Site as part of the human health RA. Therefore, a follow-on vapor intrusion assessment was conducted in 2012 and 2013. For a comprehensive discussion of the findings that assessment, please refer to the Vapor Intrusion Exposure Assessment Report (Appendix G).

The investigation concluded that vapor intrusion into buildings that overly the groundwater plume are not affected by vapor intrusion. This conclusion is based on multiple lines of evidence, including the lack of constituents above screening levels in the indoor air and corresponding soil gas or sub-slab samples (see Table 4-5 for screening levels and analytes, Table 4 in Appendix G for air results, and Table 5 in Appendix G for soil gas results). For 2012 and 2013 soil gas and sub-slab sampling locations, refer to Figure 3-3.

Although PCE was detected in the soil gas near and below the slab of the Community Center, PCE was not identified in indoor air after two rounds of sampling. Similarly, PCE was identified above the screening level in the soil gas near 305 N. 1st Avenue and near the Post Office, but was not detected in the indoor air in either location. TCE and vinyl chloride were also detected in the soil gas near the Post Office, but were not above the screening levels in the sub-slab sample or indoor air.

TCE and 1,2-DCA were the only constituents detected in indoor air in any of the buildings at concentrations above the screening level. TCE appears to be related to indoor sources, based on the lack of TCE in corresponding sub-slab or soil gas samples. Note: the available head space above the groundwater table near the Sportsman Bar & Grill was insufficient for successful collection of a soil gas sample. A minimum of 5.5 feet of headspace was needed, and depth to water was 5 feet bgs.

There appears to be at least one outdoor air source of 1,2-DCA, indicated by the generally consistent concentrations in the indoor air and in some of the outdoor air samples, and by the absence of 1,2-DCA above screening levels or the method reporting limit in the soil gas or sub-slab samples. According to literature sources, 1,2-DCA is an additive to many common products, including leaded gasoline, paints, and adhesives, such as those used in wallpaper glue or carpeting (ATSDR, 2015). The presence of TCE in one of the outdoor air samples collected in 2013 (OA3) suggests that there is a source near the Site.

Helium detected in three of the sub-slab samples collected in 2012 indicated the potential infiltration of ambient air, which suggests that the detected constituents in these samples are underestimated. Helium detections are included on Table 5 of Appendix G. However, each building with sub-slab sampling data had at least one sample result with no helium detected. Therefore, there is quality sub-slab data that indicate the lack of vapor intrusion.

4.4 Summary of Site Investigation Conclusions

Soil, air, and groundwater have been characterized at the Site. Vapor intrusion is not a pathway of concern for the Site, except in the event that a building is constructed in the Source Area. The lateral extent of soil impacts down to 15 feet bgs is generally confined to the Property, with a small area also impacted in the Source Area and on the adjacent property to the south (see Figure 4-1). The extent of groundwater impacts has been delineated and is shown on Figure 4-2, and the Source Area and an estimated Site boundary are shown on Figure 1-2.

5 LAND USE EVALUATION AND BENEFICIAL WATER USE EVALUATION

The following section includes the land use evaluation (LUE) and beneficial water use evaluation (BWUE) for the Site.

5.1 Objective

The objective of the evaluations is to identify, to the extent practical, the current and reasonably likely future use of land, surface, and groundwater at the Site. A site is defined in WAC 173-340-200 as “any site or area where a hazardous substance, other than a consumer product in consumer use, has been deposited, stored, disposed of, or placed, or otherwise come to be located.”

The Site is defined by the nature and extent of contamination associated with one or more releases of hazardous substances prior to any cleanup of that contamination. The estimated lateral extent of the Site, shown on Figure 1-2, is based on the nature and extent delineation discussed in Section 4.

5.2 Methodology

There are three basic steps in a combined LUE/BWUE. The first step is to develop an understanding of a site's hydrogeologic setting, as described in Section 2. The second step is to delineate the site, based on nature and extent (Section 4). The third step is to document and evaluate current and reasonably likely future land use and beneficial water uses at the site; this is the focus of this section.

The evaluation of beneficial uses of water at the Site includes information about the following:

- Hydrogeologic setting
- Historical, current, and reasonably likely future beneficial uses of groundwater
- Other relevant factors

The evaluation of land use on and next to the Site includes:

- Current land uses
- Zoning, comprehensive plan, and other land use designations
- Land use regulations from any governmental body having jurisdiction
- Other relevant factors

5.3 Beneficial Uses of Groundwater

According to MTCA, groundwater CULs are based on estimates of the highest beneficial use and the reasonable maximum exposure expected under both current and potential future site use conditions (WAC 173-340-720[1][a]). The highest beneficial use of groundwater is discussed in this section. Potential exposure scenarios are discussed in Section 5.9.

Based on hydrogeological conditions observed at the Site and on regional topography (see Figures 2-4 and 2-5), the following conditions are present:

- Shallow groundwater originating from the Site flows west to almost due north, forming a groundwater ridge.
- Shallow groundwater originating from the Site likely does not discharge to Lake River.

Chemically affected groundwater originating from the Site is not likely to result in IHS concentrations above CULs in surface water. Lake River is located within 0.5 mile of the Property. Investigations completed by the Port indicate that PCE concentrations in groundwater were present only in the deeper portion of the upper WBZ and that the deeper upper WBZ was unlikely to discharge to Lake River. Conservative groundwater modeling showed that IHSs would not reach Lake River (MFA, 2007). At Ecology's direction, the 2007 BIOCHLOR groundwater model conservatively assumed that no reductive dechlorination of PCE was occurring, and modeled attenuation of PCE based only on dispersion, adsorption, and first order decay. Both 30- and 100-year model runs indicated that PCE concentrations in groundwater would attenuate to levels below the most stringent regulatory criteria (surface-water CULs) before discharging to Lake River. Based on these modeling efforts, it is unlikely that groundwater discharges to Lake River will pose unacceptable risks to receptors. Groundwater

sampling on the Ridgefield National Wildlife Refuge, performed at the direction of Ecology also showed that groundwater impacts from Cell 3 had not impacted groundwater beneath the refuge. Therefore, CULs for groundwater protective of surface water were not considered to be appropriate by Ecology.

The region of study for the beneficial water use determination was conservatively defined as within a 0.5-mile radius of the Site. The current, historical, and reasonably likely future beneficial water uses were evaluated for groundwater and surface water in the region of study.

5.4 Current and Historical Beneficial Water Uses

Four active water wells and two water rights records in the study area were identified (see Figure 5-1). The current beneficial use listed for two of the four water wells is irrigation. The remaining two wells are municipal water wells, which are operated by, and used to supply drinking water for, the city. The municipal water wells draw from a deeper aquifer than the contamination-impacted aquifer units identified beneath the Site. The two current water rights are for domestic general, irrigation, and stock watering. Both of the water rights are for springs located over a quarter mile east. Well logs and water rights documentation are located in Appendix A; however, no documentation was found for water right number 510764.

There are no surface water bodies on the Site. The nearest point of Lake River is located approximately 780 feet to the west of the Site. Several streams were located within a half-mile radius of the Site, with the closest stream horizontal distance (Gee Creek) being approximately 1,800 feet east of the Site. Temporary water right permits were issued to Dixon Marine Services, Inc., for surface water withdrawal from Lake River for use in dredging procedures; this permit expired in 2014.

5.4.1 Contact with Municipal, Public, and Private Water Supplies

The City provides the area (including the region of study) with municipal water from groundwater sources. The water source is water wells located in Abrams Park, east of the Site.

5.4.2 Well Records Review for Groundwater

Logs for water wells in the region of study were obtained from Ecology's Washington State Well Log Viewer database, which allows the user to access well log reports for a specific township, range, and section (Ecology, 2009a). Well log reports typically include information such as well location, well type and construction details, installation date, depth, depth-to-water measurements, and use. The study area included parts of section 19 (township 4 north, range 1 east of the Willamette Meridian); and sections 13 and 24 (township 4 north, range 1 west of the Willamette Meridian; Figure 5-1). Water well logs for these sections were evaluated and are included in Appendix A.

These well locations were plotted using coordinates from the Washington State database; four wells were identified as being in the area of study (see Figure 5-1). Two of the four wells are private wells used for irrigation. The remaining two wells are owned by the City and are municipal drinking water wells.

Municipal Well 10 total depth is 135 feet and it is screened in the Troutdale sand unit between 106 feet and 130 feet bgs. Municipal Well 7 total depth is 195 feet and it is screened in the Troutdale sand unit from approximately 145 feet bgs to 186 feet bgs.

The two private irrigation wells are screened from 160 to 170 feet and 341 to 357 feet bgs, respectively, and are both completed in the Troutdale sand unit, same as the municipal wells.

Impacts at the Site have been limited to the shallower Pleistocene alluvium. Impacts to the potable aquifer on the Port property are limited to the lower portion of the upper WBZ..

There are no domestic or municipal water supply wells in the area of study that could potentially be impacted by contamination from the former Park Laundry.

5.4.3 Water Rights Review

Ecology Water Resources is responsible for apportioning water rights in Washington State and maintains a database of water rights (Ecology, 2009a). The water right database was queried for water rights in the region of study. Two surface water right diversion areas or collection points were identified (Figure 5-1). Copies of the water rights and the water right certificate are provided in Appendix A.

The water rights identified within a half-mile radius of the Site are designated for the following water uses: domestic, irrigation, and stock watering. However, Site-related impacts are not likely to affect groundwater withdrawals for these water rights because the water rights are for springs (see Figure 2-4 and 5-1).

5.5 Reasonably Likely Future Beneficial Water Uses

5.5.1 Surface Water

There are no surface water bodies on the Site. There are no current surface water rights associated with Lake River, and only one stream within a half-mile radius—Gee Creek (see Figure 2-4 for area topography). It is unlikely that surface water from Lake River will be used as a drinking water source in the future because of possible stormwater runoff from multiple surrounding industrial and commercial properties and the availability of deeper groundwater as a local drinking water source. However, Lake River, a salmon-bearing stream, is known for recreational fishing.

5.5.2 Groundwater

Groundwater under and near the Site is not used or anticipated to be used as a source of drinking water. The city's water supply wells are screened in the Troutdale Formation. This Site investigation has demonstrated that impacts are limited to the upper Pleistocene alluvium aquifer, which overlies the Troutdale Formation and is hydraulically separated from it by aquitards.

The city is in an area of the Salmon/Washougal basin where groundwater withdrawals are subject to the Water Resource Inventory Area 28 Instream Resources Protection Program rule (WAC 173-528), which restricts current and future groundwater use. Under this rule, limited reserves of groundwater are available for new withdrawals, and new water rights are difficult to obtain. Therefore, it is highly unlikely that any new domestic or commercial potable groundwater wells will be developed in the area.

Further, the State of Washington has minimum standards for construction and maintenance of wells that specifically require a surface seal to extend from land surface to a minimum depth of eighteen feet (WAC 173-160-231). In the upper terrace of the Site, the upper WBZ is not deep enough to support this requirement. Therefore, a well could not be constructed throughout most of the Site, including the source area and directly downgradient. The Port will implement a restrictive covenant on its property preventing the installation of a water supply well and the use of groundwater on its property.

Based on this information, contaminated groundwater associated with the Site will not be used for drinking water.

5.6 Land Use Evaluation

5.6.1 Current Zoning

Current zoning of the Site is Downtown Mixed Use, Low-Density Residential, and Medium-Density Residential, as shown in Figure 5-2.

5.6.2 Surrounding Zoning and Land Use

Most of the zoning within a half-mile radius of the Property is mixed-use and residential. Directly east of the Property is a small park/open space consisting of a skate park. Another open space is 300 feet north of the Property. Properties to the west of the Property are designated as waterfront mixed use, and even farther west/northwest, the Ridgefield National Wildlife Refuge (RNWR) runs parallel to Lake River. Other designated zoning within a half-mile radius includes Urban Public and a range of Low-Density Residential.

5.6.3 Reasonably Likely Future Land Uses

As part of an Ecology Integrated Planning Grant, a real estate market study and feasibility and impact study were conducted for the Property by E.D. Hovee & Company, Inc. (E.D. Hovee, 2014, 2015). Based on the findings, E.D. Hovee suggested that two iterations of development could be realized on the Property: townhouses or retail and apartment mixed-use. The City is also considering acquisition of the Property and adjoining lots to install a new public library.

5.6.4 Conceptual Site Model

The CSM describes potential chemical sources, release mechanisms, environmental transport processes, exposure routes, and receptors. The primary purpose of the CSM is to describe pathways

by which human and ecological receptors could be exposed to site-related chemicals. A complete exposure pathway consists of four necessary elements: (1) a source and mechanism of chemical release to the environment, (2) an environmental transport medium for a released chemical, (3) a point of potential contact with the impacted medium (referred to as the exposure point), and (4) an exposure route (e.g., soil ingestion) at the exposure point. Elements of potentially complete exposure scenarios for human health are discussed below and shown on Figure 5-3.

The CSM and exposure scenarios for a site play a role in selection of cleanup standards.

5.7 Source Characterization

Based on previous investigations and the lack of evidence of underground storage tanks on the Property, the source of the PCE plume is most likely surface releases from the former dry cleaning operation. The volume of PCE released has not been estimated because of insufficient information.

5.8 Fate and Transport Processes

If the Property was impacted by historical operations from Park Laundry, then the impacts likely were from either surface releases or broken piping. The surface releases would have infiltrated the vadose zone to groundwater. Impacts may also have originated from damaged wastewater pipes if chemicals were disposed of in drains. The subsurface piping may also have created preferential transport pathways.

5.9 Potential Exposure Scenarios

The Property and Source Area are zoned commercial, are currently vacant, and contain no structures. The Property and Source Area could be used for numerous commercial activities, such as ground-floor commercial space with upper-story living units; retail, restaurants and lodging; and service industries, among other types of commercial use. Therefore, it is reasonably possible that commercial workers and/or residents will occupy the Property and Source Area at some time in the foreseeable future. Figure 5-3 summarizes the CSM.

The following pathways were considered in this RI:

- Incidental ingestion of and dermal contact with chemicals in subsurface soil and groundwater
- Inhalation of fugitive dusts generated from subsurface soil, and inhalation of vapors emanating from subsurface soil
- Inhalation of indoor air vapors from groundwater and subsurface soil due to vapor intrusion into the neighboring buildings
- Ingestion, dermal contact, and inhalation of chemicals volatilizing from tap water from groundwater

Dermal contact, and inhalation of chemicals volatilizing from groundwater by an excavation worker. The groundwater ingestion, dermal contact, and inhalation of chemicals volatilizing from tap water from groundwater pathways are subject to the results of the BWUE and completion of a non-potability determination that meets the requirements of MTCA 173-340-720(2) (see Sections 4.2.3 and 5.9.3). Notwithstanding that groundwater east of Railroad Avenue meets Ecology's non-potability criteria, the groundwater from the non-potable aquifer recharges groundwater west of Railroad Avenue that is considered potable, and as directed by Ecology, cleanup levels protective of potable groundwater will be applied throughout the Site.

PCE in groundwater from the former Park Laundry extends onto Cell 3 property and the boat launch parking area at the port. In the RI completed by the Port for the Cell 3 property, PCE contamination found in the deeper portion of the upper WBZ was shown not to impact Lake River (MFA, 2007). The Port completed investigations for PCE on the port property and west of Lake River in the RNWR. The Port also conservatively completed modeling for PCE migration to Lake River and found that PCE would not impact Lake River. Based on the Port's assessment, aquatic and human receptors (in terms of consumption of organisms) are not considered potential receptors for the Site. As mentioned above, the Port has implemented an environmental covenant on its property that prohibits the use of groundwater.

5.9.1 Soil

As discussed in Section 4.1, surface soil impacts are limited to the Property and two small areas below the water table in the Source Area and south of the Property. Surface soil PCE concentrations on the Property are above MTCA Method A CULs (Figure 4-1). Thus, the soil inhalation, ingestion, and dermal contact pathways are considered complete.

5.9.2 Vapor

Section 4.3 describes investigation results for vapor intrusion and soil vapor exposure at the Site. The data discussed in Section 4.3 show that vapor intrusion into existing buildings is not a complete exposure pathway. There is still the potential for vapor intrusion risk in the Source Area if the properties are developed.

5.9.2.1 Refined CSMs

MFA prepared CSMs for each of the buildings included in the vapor assessment, consistent with Section 3.2 of Ecology's draft vapor intrusion guidance (Ecology, 2009b). The results are provided in Appendix G.

5.9.3 Groundwater

Figure 4-2 illustrates the groundwater plume at the Site as of September 2016. As determined in the final RI/FS for the PWT Site, groundwater discharge to surface water is not a complete pathway, based on evaluations completed by the Port (MFA, 2007 and 2013) and Ecology's determination in the 2013 Consent Decree for the Pacific Wood Treating Site.

In addition, no water wells near the Site draw from the upper WBZ impacted by PCE and, based on aquifer testing data (refer to Section 4.2.3), groundwater of the upper WBZ on the upper terrace beneath the source area and immediately downgradient fits the definition of nonpotable (MTCA 173-340-720(2)). In addition, the State of Washington has minimum standards for construction and maintenance of wells that specifically require a surface seal to extend from land surface to a minimum depth of eighteen feet (WAC 173-160-231). In the upper terrace of the Site, the upper WBZ is not deep enough to support this requirement. Therefore, a well could not be constructed throughout most of the Site, including the source area and directly downgradient. Thus, dermal contact or ingestion of groundwater is not a potential pathway except in areas of the plume where groundwater does not meet the definition of nonpotable (i.e., in monitoring wells MW15 and MW16 and downgradient beneath the port) or when groundwater is encountered during construction or other underground work. While groundwater beneath the port is potentially potable, groundwater use on the port site will be prohibited through an environmental covenant that restricts groundwater use.

5.9.3.1 Hydrogeologic CSM

The current hydrogeologic CSM identifies two aquifer units present at the Site, as discussed in Section 2. On average, groundwater has been observed in the sand and silty sand (Pleistocene alluvium) of the upper terrace at approximately 10 feet bgs in the upper WBZ, which overlies a clay aquitard. The Property is located on the upper terrace, where groundwater flow varies from west to almost due north, forming a groundwater ridge. Groundwater contours at the Site mimic topography and become steeper to the west, with the gradient flattening on the lower floodplain terrace. Groundwater flow from the upper WBZ in the upper terrace appears to be connected to groundwater in the upper WBZ beneath the lower terrace as the clay unit pinches out to the west with the topographic change and the upland Pleistocene alluvium silty sand unit comes into contact with the lower terrace Pleistocene alluvium sandy gravel unit.

On the Property and the upper terrace, the clay unit is approximately 40 feet thick, with the bottom around 55 to 60 feet bgs. Underlying the clay unit is a silty gravel (the Upper Troutdale Formation). The Property domestic water was historically supplied by the City. No water supply wells are operating on the Property or have been identified on neighboring properties included in the Site (Figure 5-1). City water supply wells located in Abrams Park, approximately 2,500 feet horizontal distance from the Site, are screened in the Upper Troutdale Formation (lower WBZ). Therefore, groundwater impacted by PCE and its degradation products in the alluvial upper WBZ does not present an immediate risk to drinking water wells. To qualify as nonpotable, according to WAC 173-340-720(2), groundwater beneath the Site cannot serve as a current source of drinking water, and hazardous substances from contaminated groundwater will not be transported to groundwater that could be potable. Based on the lack of beneficial uses on the Site and determinations of potential beneficial use, the Site meets these qualifications on the upper terrace beneath the source area and immediately downgradient. However, there is the potential for non-potable groundwater from the upper terrace (and hazardous substances within it) to be transported to groundwater that could be potable. Therefore the highest beneficial use for the Site is for drinking water. See Section 5.5.2 for a more detailed discussion of drinking water and wells in the area.

5.10 Terrestrial Ecological Evaluation

A TEE is required at all MTCA sites where there has been a release or threatened release of a hazardous substance that may pose a threat to human health or the environment. The TEE procedure is structured with the intent to protect terrestrial wildlife at industrial and commercial sites, terrestrial plants, and soil biota; and terrestrial wildlife at other sites, as provided under WAC 173-340-7490(3)(b).

The Property is covered with low-growing vegetation (primarily grasses and weeds) and is sprayed at least once a year to control weeds. The Property is zoned as Downtown Mixed Use and is surrounded by commercial properties and paved roads that are unattractive to wildlife. A vacant lot with some mature trees is directly north; a City-owned alleyway and a concrete skate park are directly east; a police station is directly south; and Main Avenue and a restaurant are directly west of the Property. Adjacent to the railroad corridor, 500 feet west of the Site, are some undeveloped areas with low-growing grasses (see Appendix K). An overpass originating at the end of Pioneer Street that will pass through the undeveloped area and across the railroad corridor is currently under development.

Local and migrating populations of birds and wildlife in the area are most likely to use the high-quality habitat the nearby RNWR provides. This habitat is located more than 500 feet west of the Site, along Lake River and the RNWR River "S" Unit, and more than 500 feet to the northwest near Carty Lake in the RNWR Carty Unit. Based on Washington Department of Fish and Wildlife information, threatened/endangered and priority species and habitats are unlikely to be present at or within 500 feet of the Property (see Appendix K).

An initial step in the TEE process is to determine whether a site qualifies for a TEE exclusion. If the site meets at least one of the four exclusionary criteria, then no further evaluation of ecological risk is necessary (WAC 173-340-7491). The four exclusionary criteria are: (1) contamination is present only below the point of compliance (POC) (i.e., below 15 feet bgs, provided institutional controls to limit exposure to zero to 6 feet bgs are not in place or planned); (2) incomplete exposure pathway (i.e., all soil will be covered by physical barriers); (3) type of contamination and proximity to ecological receptors (i.e., the site is located on or near a limited amount of undeveloped land); and (4) all concentrations are below background levels. MTCA does not identify the chemicals of concern at the Site (chlorinated VOCs) as priority contaminants for the TEE and no MTCA screening values are available for these VOCs. However, based on a literature review, concentrations between zero and 15 feet bgs exceed available USEPA screening criteria.⁵ It is therefore concluded that exclusionary criterion 1 is not met. The Site does not meet exclusionary criteria 2 and 3, as it is uncertain whether future development would cover all areas of potential exposure, and the Site is within 500 feet of more than 1.5 acres of undeveloped land. Chlorinated VOCs are anthropogenic and therefore exclusionary

⁵ For example, soil concentrations exceed the USEPA Region 5 ecological screening level (ESL) of 9.92 milligrams per kilogram for PCE at locations GP52-S-12.5 and B8-S-14.5. Note that these depths (12.5 feet and 14.5 feet, respectively) are below the typical biologically active zone of zero to 6 feet bgs; however, zero to 15 feet bgs must be considered, provided institutional controls to limit exposure to zero to 6 feet bgs are not in place or planned. ESLs are developed to support precautionary screening assessments, and exceedances do not necessarily indicate unacceptable ecological risk.

criterion 4 is not met. Since the Site cannot be definitively excluded from the TEE process, a simplified or site-specific TEE is required.

The simplified TEE is intended to identify only those sites that do not have substantial potential for posing a threat of significant adverse effects to terrestrial ecological receptors and that therefore may be removed from further ecological consideration during the RI and cleanup process (WAC 173-340-7492). MTCA specifies that a simplified TEE applies, provided the site is (1) not located on or adjacent to natural areas, (2) not used by vulnerable species, (3) less than 10 acres of native vegetation in the site vicinity is present, and (4) there is no risk to significant wildlife populations, as determined by Ecology (WAC 173-340-7491). A simplified TEE is appropriate; the Site is located in a developed town center with minimal surrounding native vegetation, and no species of concern are identified for the Property (see Appendix K).

WAC 173-340-7492(2) provides the steps necessary for conducting the simplified TEE. The simplified TEE can be ended if any of three criteria (exposure analysis, pathway analysis, and toxicity analysis) are met. MTCA Table 749-1 provides steps for conducting the exposure analysis to determine the likelihood that land use at a site and the surrounding area will result in substantial wildlife exposure. If a low likelihood is demonstrated, MTCA requires no further evaluation and concludes that a site does not pose a substantial threat to potential ecological receptors.

The exposure analysis and site visit were conducted by MFA on October 31, 2014 (see Appendix K). A photo log of the Property is provided in Appendix K. The completed MTCA Table 749-1, included in Appendix K, shows that the Property is unlikely to pose a threat to ecological receptors and no further evaluation is necessary. The table in Appendix K shows the rationale for the scoring on Table 749-1.

5.11 Potential Receptors

Based on the analysis above, the following are potential human and ecological current and future receptors:

- Occupational workers
- Residents
- Construction/trench workers

6 RISK ASSESSMENT

According to MTCA, the cleanup standards for a particular site have two primary components: chemical-specific CULs and POCs. The CUL is the concentration of a chemical in a specific environmental medium that will not pose unacceptable risks to human health or the environment. The POC is the location where the CUL must be met.

6.1.1 Soil CULs

MTCA provides three different options for establishing CULs for human health: Methods A, B, and C. Method A is designed for cleanups at relatively simple sites, such as those that are small and that have only a few hazardous substances. For Methods B and C, either the standard or the modified approach can be used. The standard method uses generic default assumptions to calculate CULs, and the modified method allows for site-specific adjustments to some assumptions when calculating CULs. Method B can be used at any site. Method C is used primarily for industrial sites.

The Property historically has been used for retail and it is anticipated that it will be used for similar purposes in the future. The Site is impacted mainly with PCE. The impacts appear to be limited in extent. Therefore, Method A CULs for unrestricted land use are the soil CULs for the Site.

These CULs are calculated using reasonable maximum human health exposure assumptions with target risk levels set at the MTCA acceptable risk level. In addition, as Method A CULs are not available for all VOCs, these were compared to Method B CULs.

Soil CULs are shown in Tables 3-2 and 3-3.

The soil POC is the depth at which soil CULs shall be attained. The standard POC for soil is within 15 feet of the ground surface throughout a site. This standard POC applies to soil on the Site.

6.1.2 Groundwater CULs

Method A CULs are considered applicable for most chemicals at the Site because it is a simple site (e.g., relatively few hazardous substances). When Method A CULs were not available, Method B CULs were used.

Groundwater CULs are shown in Tables 3-5, 3-6, and 4-2.

The POC for groundwater is the entire upper WBZ at the Site (WAC 173-340-720[8][b]). In addition, groundwater throughout most of the Site qualifies as nonpotable, based on WAC 173-340-720(2) and the following demonstrations:

1. The Site is currently not a source of drinking water (Section 5).
2. The upland terrace portion of the Site, which includes the Source Area, is not a potential future source of drinking water, based on insufficient yield, as demonstrated by site-specific yield calculations (Section 4.2.3) and the fact that the aquifer is too shallow to construct a well in compliance with WAC 173-160 and in accordance with normal domestic water well construction practices in the area. This leaves groundwater beneath the transition zone from the upper to the lower terrace and beneath the port as potable. However, groundwater use on the port site will be prohibited through a restrictive covenant.

3. It is unlikely that hazardous substances from the Site will reach groundwater that is a current or likely potential future source of drinking water. Drinking water in this neighborhood is already supplied by the City of Ridgefield.
4. Because groundwater from the non-potable portion of the Site recharges groundwater in the potable portion of the Site (Port property east of Railroad Avenue), CULs protective of drinking water apply to groundwater throughout the Site.

6.1.3 Air CULs

Acceptable indoor air quality is defined in WAC 173-340 as indoor air concentrations resulting only from vapor intrusion that do not exceed applicable CULs. Draft Method B CULs were used to assess indoor air risk for the Site.

MTCA regulations do not contain requirements for achieving soil vapor cleanup standards; however, soil gas concentrations were compared to draft Method B screening levels for assessment purposes.

Indoor air CULs are shown in Tables 4-4 and 4-5.

6.2 Screening

6.2.1 Soil

Figure 4-1 illustrates the lateral extent of the soil impacts (down to 15 feet bgs) in the Source Area. The highest concentration of PCE in surface soil (0.5 foot bgs) was detected in GP51 at a concentration of 147 ug/kg, which is above the MTCA Method A soil CUL of 50 ug/kg. Surface-soil concentrations in four borings (GP38, GP44, GP45, and GP46), located on the eastern end of the Property and adjacent to the south, were also above the Method A CUL. The highest concentration in sub-surface soil was detected below the water table in GP52 (12.5 feet bgs) at a concentration of 316,000 ug/kg. Several other locations on the eastern half of the Property and directly adjacent to the north had exceedances in sub-surface soil to 15 feet bgs (including B5, GP43, GP46, GP47, GP48, GP51, and GP55). In addition, there was one soil exceedance in the upper 15 feet (at 14.5 feet) in location B8.

As mentioned in Section 4, additional soil samples were collected from 1 to 2 feet into the upper confining clay unit in four deeper borings (B5, B7, B8, and B9) and deeper samples up to approximately 25 to 27 feet into the clay unit (B5, B8 and B9) to assess the possibility of migration of PCE in groundwater through the clay unit. PCE concentrations in B5 and B8 (1,880 ug/kg and 4,370 ug/kg, respectively) a few feet into the clay were lower than those in soil directly above the clay (7,490 ug/kg and 31,400 ug/kg, respectively); however, all results were above the Method A CUL (see Table 3-2). Concentrations of PCE in soil in B7 and B9 increased a few feet into the clay unit, as compared to concentrations on top of the clay. However, in B5, B8, and B9, by 40 feet bgs if not shallower, soil concentrations of VOCs in all deeper locations were non-detect.

6.2.2 Groundwater

6.2.2.1 Reconnaissance Groundwater Samples

Results from reconnaissance groundwater samples are shown in Table 3-6. PCE detections in the upper WBZ indicate that the highest concentration of PCE is on the eastern side of the Property, similar to surface soil sampling results. The highest detection of PCE was at GP52, at a concentration of 37,700 ug/L, above the Method A CUL of 5 ug/L. This is near boring GP38, with a slightly elevated detection of PCE in near-surface soil. Concentrations of this magnitude have not been replicated in monitoring wells; however, several reconnaissance borings on the eastern half of the Property had elevated concentrations of PCE on or near that order of magnitude, suggesting a source of contamination in that area.

6.2.2.2 Quarterly Monitoring Well Sampling

Twenty groundwater monitoring wells have been installed to enable complete characterization of the vertical and horizontal extent of groundwater contamination at the Site. Quarterly groundwater monitoring events have been conducted since March 2012. Locations of the monitoring wells are shown in Figure 4-2 and analytical data are summarized in Table 4-2.

Groundwater sampling and analysis at the Site continue to focus on the characterization of PCE and its possible degradation products (e.g., TCE, cis-1,2-DCE, trans-1,2-DCE, and vinyl chloride). TCE has been detected above MTCA CULs; correlation to the PCE groundwater contamination is discussed in Section 4.2.4.

The highest concentrations of PCE in groundwater during the most recent sampling event, September 2016, were measured in samples from MW03 (8,710 ug/L) and MW05 (846 ug/L), in the Source Area and northwest of the Property (see Table 4-2). While earlier reconnaissance data indicated the presence of elevated concentrations of PCE on the Property (up to 37,700 ug/L), concentrations of PCE measured in monitoring well MW01, which is installed on the eastern portion of the Property, have consistently been much lower than the earlier reconnaissance sample results. The concentrations in MW01 are also significantly lower than the concentrations in MW03 and MW05 on adjoining properties. The PCE concentrations in monitoring wells from the September 2016 groundwater monitoring sampling event are shown on Figure 4-2.

Figure 4-2 shows the distribution of PCE and/or TCE exceeding MTCA CULs for the September 2016 sampling event. Trend plots for PCE in groundwater are included in Appendix H. Most wells continue to show some variability, while stable trends are evident in certain monitoring wells. PCE concentrations in eight wells (MW02, MW06, MW08, MW14, MW17, MW18, MW19, and MW20) have been below CULs for six or more quarters of groundwater monitoring. Although above CULs, MW01 and MW04 appear to show a decreasing trend in PCE concentration. The remaining ten wells continue to show variability in PCE concentrations, with MW10 and MW11 showing slight evidence of increasing PCE concentration trends.

The relationship between PCE and TCE concentrations is discussed in Section 4.2.4.

6.2.3 Air

Despite the identification of risk factors, the evaluation did not identify vapor intrusion into any of the buildings on the Site. This supports the conclusion that there is no current indoor air exposure resulting from vapor intrusion on the Site; both Ecology and the Washington State Department of Health agreed with this conclusion (Department of Health, 2013). The potential for future exposure in the Source Area should be considered when the properties are developed. For a more detailed discussion of findings from the vapor assessment, refer to Appendix G.

6.3 Conclusion

Based on the data and as discussed above, there are exceedances of MTCA Method A criteria in soil beneath the Property and directly adjacent, and in groundwater extending off Property. If a building is constructed in the Source Area, vapor intrusion should be considered, as there is a potential for exposure.

It is not likely that the groundwater in the upper WBZ will be used as drinking water. MTCA requires that any concentration exceeding Method A concentration levels be addressed as if groundwater would be used for drinking water. However, it has been shown that the groundwater beneath the upper terrace (the Source Area and immediately downgradient) qualifies as nonpotable, and because of the shallow aquifer, it is not feasible to construct a water well per state regulations; only the transition zone area and the lower terrace (beneath the port) are potentially potable. Plus, groundwater use on the port site will be prohibited through a restrictive covenant. As discussed earlier, CULs protective of groundwater will be applied throughout the Site.

7 DEVELOPMENT OF CLEANUP ACTION ALTERNATIVES

Soil and groundwater concentrations in the established POC that exceed applicable CULs will be addressed in some manner (e.g., removal, institutional controls, treatment, monitored natural recovery). The sections below outline the technology screening conducted and the proposed alternatives to be evaluated.

7.1 Technology Screening

A preliminary screening of applicable technologies was completed based on technologies discussed in the Federal Remediation Technologies Roundtable Screening Matrix (FRTR, 2002), as well as on commonly used remediation methods. The following technologies were retained for further consideration in the selection of a cleanup alternative:

- **Natural Attenuation:** Natural attenuation, to the extent to which it is occurring on site, is considered; however, it is not relied on for full remediation. Several studies have

indicated that concentrations of PCE and other chlorinated solvents are reduced by reductive dechlorination under anaerobic conditions; however, there is limited evidence for anaerobic biodegradation of chlorinated organics via natural attenuation (USEPA, 1998). A preliminary analysis of natural attenuation, conducted by MFA (Section 4.2.4), showed limited evidence of natural attenuation. That said, decreases in source area concentrations will promote decreases in downgradient concentrations as a result of dispersion.

- **Excavation and Off-Site Disposal:** Excavation would remove from the Property all or some of the soil exceeding CULs. With excavation and off-site disposal, contaminated material is removed and transported to permitted, off-site disposal facilities.
- **In Situ Groundwater Treatment:** In situ groundwater treatment remediates the groundwater in place. Chlorinated solvents are reduced by two methods: adsorption and reductive dechlorination. Both methods are enhanced by healthy microorganism populations that occur naturally in the subsurface, and/or that are coupled with chemical compounds to enhance microorganism reproduction and growth. The in situ groundwater treatment introduces the chemical and biological compounds into the contaminant plume, often by injection, to reduce the contaminant concentrations. This process is often cost effective and more easily implementable than other remedial technologies. Implementation of this technology does not guarantee that concentration levels will be reduced to CULs.
- **Institutional Controls:** Institutional controls (e.g., a restrictive covenant) may be required to reduce or limit future exposure of receptors to soil and groundwater containing residual IHSs at concentrations above relevant CULs. Deed notifications inform potential purchasers of the presence of IHSs in soil, soil gas, and/or groundwater, and may limit activities or land use as well as defining requirements for future site-redevelopment activities.

7.2 Cleanup Alternatives

This section summarizes seven remedial alternatives for addressing the contamination identified at the Property (shown on Figure 7-1). These alternatives represent the most likely cleanup scenarios and encompass a range from limited to extensive remedial actions. The cleanup alternatives focus on vadose zone soil (i.e., soil above typical groundwater levels), saturated soils, and groundwater impacted by PCE and its degradation products.

7.2.1 Alternative 1: No Action

The Property will remain in its current state.

7.2.2 Alternative 2: Soil Excavation up to 15 feet bgs, Institutional Controls, and Groundwater Monitoring

Alternative 2 includes the following components:

- Remedial action:
 - **Soil:** Excavate and characterize soil impacts and dispose of the affected soil at a Subtitle C landfill. The excavation extent is centered primarily on the Property in a 1,700-square-foot area to approximately 15 feet bgs and a 300-square-foot area to 3 feet bgs (approximately 1,000 cubic yards total) (Figure 7-2). Collect confirmation samples from excavation sidewalls. Dewater excavation and characterize water for appropriate treatment and/or disposal. Backfill with clean, imported fill to existing ground surface and compact, with replacement in kind of disturbed paved areas. Decommission monitoring wells MW01 and MW21 because of damage from excavation (see Figures 7-1 and 7-2).
- Institutional controls:
 - Prohibit groundwater use on the Property for irrigation, potable drinking water, or any use requiring human contact. A contaminated-media management plan would outline management of any groundwater encountered during development. A public notice would be issued to restrict groundwater in the plume area. A vapor barrier or control system (or other Ecology approved approach) would be required for any building construction in the Source Area. Assessment may occur periodically to determine whether institutional controls are required.
- Compliance monitoring:
 - Groundwater monitoring after the remedy is implemented is required until CULs have been achieved for four consecutive monitoring events. For the purpose of the cost estimate, groundwater monitoring is assumed for 30 years and will be conducted every 18 months on wells closer to the Property (MW03, MW04, MW05, and MW06) and in the plume area (MW07, MW09, MW10, MW11, MW13, MW15, and MW16). Wells will be sampled during alternating dry (e.g., September) and wet (e.g., March) seasons to evaluate concentrations of PCE and associated breakdown products. The Port conducts groundwater monitoring for well MW47D every 18 months. See Table 7-1 summarizing the wells and monitoring schedule. The cost estimate includes costs for decommissioning monitoring wells once CULs are met.

A cost estimate for Alternative 2 is provided in Table 7-2.

7.2.3 Alternative 3: Soil Excavation up to 6 feet bgs, Focused Groundwater Remediation, Institutional Controls, and Groundwater Monitoring

Alternative 3 includes the following components:

- Remedial action:
 - **Soil:** Excavate and characterize soil impacts and dispose of the affected soil at a Subtitle C landfill. The surface soil excavation is centered primarily on the Property,

but extends to the property to the south. The soil excavation is approximately 700-square-foot and includes the areas up to 3 and 6 feet bgs collectively (approximately 250 cubic yards total) (Figure 7-2). Collect confirmation samples from excavation sidewalls. Backfill with clean, imported fill to existing ground surface and compact, with replacement in kind of disturbed paved areas.

- **Groundwater:** In situ groundwater treatment on the Property and the Source Area to include MW03, using injection points to treat PCE in groundwater. For the purpose of the cost estimate, 9,700 square feet will be treated from an average depth of 5 to 15 feet bgs with a reducing agent and enhanced bioremediation (i.e., 43,450 pounds of anaerobic EHC™ bioremediation amendment followed 30 L of by microorganism DHC inoculation to enhance degradation). The cost estimate was conservatively based on treating PCE concentrations of approximately 300,000 ug/kg in soil and 20,000 ug/L in groundwater for the Property and 100,000 ug/kg in soil and 7,000 ug/L in groundwater in the Source Area (near MW03).
- Institutional controls:
 - Identical to Alternative 2 with the addition of restrictions on soil that exceeds the CUL within the POC (e.g., disposal requirements, soil management and maintenance plan)
- Compliance monitoring:
 - Modified from Alternative 2, the compliance monitoring schedule accounts for the remedial actions and is as follows for the purpose of the cost estimate: groundwater monitoring will be conducted twice per year for two years, then every 18 months alternating dry (e.g., September) and wet (e.g., March) seasons. Wells closer to the Property (MW03 and MW05) and in the plume area (MW09, MW10, MW11, MW13, MW15 and MW16), will be sampled during each event to evaluate concentrations of PCE and breakdown products. The Port conducts groundwater monitoring for well MW47D every 18 months. All monitoring wells will be decommissioned once CULs are met. See Table 7-1 summarizing the wells and monitoring schedule.

A cost estimate for Alternative 3 is provided in Table 7-3.

7.2.4 Alternative 4: Soil Excavation up to 15 feet bgs, Focused Groundwater Remediation, Institutional Controls, and Groundwater Monitoring

Alternative 4 includes the following components:

- Remedial action:
 - **Soil:** Identical to the soil component of Alternative 2, with the addition of decommissioning monitoring wells MW01 and MW21 due to damage from the excavation.
 - **Groundwater:** Identical to the groundwater component of Alternative 3.

- Institutional controls:
 - Identical to Alternative 2.
- Compliance monitoring:
 - Identical to Alternative 3. See Table 7-1 summarizing the wells and monitoring schedule.

A cost estimate for Alternative 4 is provided in Table 7-4.

7.2.5 Alternative 5: Soil Excavation up to 6 feet bgs, Expanded Groundwater Remediation, Institutional Controls, and Groundwater Monitoring

Alternative 5 includes the following components:

- Remedial action:
 - **Soil:** Identical to the soil component of Alternative 3.
 - **Groundwater:** In situ groundwater treatment at the Property, downgradient from the property encompassing MW03 and MW05, using injection points to treat PCE in groundwater. For the purposes of the cost estimate, 28,500 square feet, from an average depth of 5 to 15 feet bgs, will be treated with a reducing agent and enhanced bioremediation. Anaerobic EHC bioremediation amendment (128,250 pounds) will be followed by 67L of microorganism DHC inoculation to enhance degradation. This cost estimate is conservatively based on treatment of concentrations of approximately 300,000 ug/kg in soil and 20,000 ug/L in groundwater on and adjacent to the Property and 100,000 ug/kg in soil and 7,000 ug/L in groundwater in the Source Area and downgradient (near MW05).
- Institutional controls:
 - Identical to Alternative 3.
- Compliance monitoring:
 - Identical to Alternative 3. See Table 7-1 summarizing the wells and monitoring schedule.

A cost estimate for Alternative 5 is provided in Table 7-5.

7.2.6 Alternative 6: Soil Excavation up to 15 feet bgs, Expanded Groundwater Remediation, Institutional Controls, and Groundwater Monitoring

Alternative 6 includes the following components:

- Remedial action:
 - **Soil:** Identical to the soil component of Alternative 2.
 - **Groundwater:** Identical to the groundwater component of Alternative 5.
- Institutional controls:
 - Identical to Alternative 2.
- Compliance monitoring:
 - Identical to Alternative 3. See Table 7-1 summarizing the wells and monitoring schedule.

A cost estimate for Alternative 6 is provided in Table 7-6.

7.2.7 Alternative 7: Soil Excavation up to 15 feet bgs, Complete Groundwater Remediation (Focused, Expanded and Reactive Zone)

Alternative 7 includes the following components:

- Remedial actions:
 - **Soil:** Identical to the soil component of Alternative 2.
 - **Groundwater:** This Alternative includes the expanded source groundwater treatment described in Alternative 5, and also includes in-situ groundwater treatment using injection points along public access ways; generating several reactive zones with EHC bioremediation amendment followed by microorganism inoculation to enhance biodegradation; and expanding the injection footprint in the upper terrace to accessible areas where PCE concentrations are above CULs (i.e., 5 parts per billion). For the purposes of the cost estimate, approximately 107,000 square feet of additional area will be treated to 20 feet bgs with 168,000 pound of bioremediation amendment.
- Institutional controls:
 - Identical to Alternative 2.
- Compliance monitoring:
 - Identical to Alternative 3.

A cost estimate for Alternative 7 is provided in Table 7-7.

8 EVALUATION OF ALTERNATIVES

8.1 Model Toxics Control Act Threshold Requirements

Cleanup actions are subject to the threshold requirements set forth in WAC 173-340-360(2)(a). Under the threshold requirements, the cleanup action shall:

- Protect human health and the environment.
- Comply with cleanup standards.
- Comply with applicable state and federal laws.
- Provide for compliance monitoring.

Alternative 1 does not pass the threshold requirements, and is not discussed further. Alternatives 2 through 7 would reduce or eliminate risk from contaminated soil through removal or a combination of removal and treatment. They would eliminate exposure pathways that pose risks to human health and the environment, and would comply with cleanup standards, which are detailed in Section 8.2.

The selected CULs are consistent with MTCA. Additionally, local, state, and federal laws related to environmental protection, health and safety, transportation, and disposal would apply to each proposed alternative. Applicable or relevant and appropriate requirements (ARARs) include:

- Resource Conservation and Recovery Act (RCRA): Disposal of any material off-site would be subject to RCRA to ensure appropriate disposal of waste, including hazardous and non-hazardous material. All alternatives include soil excavation and off-site disposal; the material will be profiled and disposed of at a licensed Subtitle C disposal facility.
- Washington State Hazardous Waste Management Regulations: Like the federal RCRA regulations, the material disposed of may be subject to hazardous waste management regulations (RCW 70.105). Unless exempt from these regulations, all waste will be handled according to these regulations.
- The [Washington] State Environmental Policy Act (SEPA): The SEPA process is undertaken when a governmental entity makes a decision. A SEPA checklist is completed by the lead governmental agency to make a determination of impact.
- Underground Injection Control (UIC) Regulations: injection of material into the subsurface is subject to UIC regulations requiring permitting of the project prior to injections. If a selected alternative includes injections, the required permits will be obtained.

During remedial design, the selected alternative would be designed to comply with applicable, relevant, and appropriate requirements.

There are three types of compliance monitoring: protection, performance, and confirmational. Protection monitoring is designed to protect human health and the environment during the construction and operation and maintenance phases of the cleanup action. Performance monitoring confirms that the cleanup action has met cleanup and/or performance standards. Confirmational monitoring confirms the long-term effectiveness of the cleanup action once cleanup standards have been met or other performance standards have been attained. The cleanup alternatives will meet this provision, as they will incorporate long-term monitoring. All of the alternatives have a similar assumed long-term monitoring timeframe at 30 years; and therefore all alternative have the same restoration timeframe based on the factors identified in WAC 173-340-360(4).

8.2 Evaluation Factors

MTCA states that in the selection of a cleanup alternative, preference shall be given to “permanent solutions to the maximum extent practicable.” “Permanent” is defined in WAC 173-340-200 as a cleanup action in which the cleanup standards of WAC 173-340-700 through 760 are met without further action being required at the site being cleaned up or at any other site involved with the cleanup action, other than the approved disposal of any residue from the treatment of hazardous substances. For the purposes of this analysis, Alternative 7 is the most practicable permanent solution and the baseline against which all alternatives are evaluated.

In order to determine the “maximum extent practicable” for each alternative, a disproportionate-cost analysis outlined in WAC 173-340-360(3)(e) is used. Costs are determined to be disproportionate to benefits if the incremental cost of a more expensive alternative over that of a lower-cost alternative exceeds the incremental degree of benefits achieved by the more expensive alternative. Consistent with WAC 173-340-360(3)(f), the evaluation criteria used were a mix of qualitative and quantitative factors, including protectiveness, permanence, effectiveness over the long term, management of short-term risks, technical and administrative implementability, and consideration of public concerns.

The cleanup alternatives are evaluated by the criteria below. See Table 8-1 for a quantitative ranking of evaluation factors.

8.2.1 Protectiveness

Protectiveness is a factor by which human health and the environment are protected by the cleanup action, including the degree to which existing risks are reduced; the time required to reduce risk at the facility and attain cleanup standards; on-site and off-site risks resulting from implementing the cleanup action alternative; and improvement of the overall environmental quality. Generally, all of the alternatives are protective because there is no complete exposure pathway at the Site with the exception of in the Source Area. All of the alternatives will reduce contamination.

Alternative 2 has a lower rating for protectiveness: human and ecological exposure to soils exceeding CULs is minimized by removal of the soil from the Site; however, treatment of groundwater would not be addressed in this alternative. Alternatives 3, 4, 5, 6, and 7 also address soil exceeding CULs by

removal from the Site, but compared to Alternative 2, they hasten the groundwater remediation and are expected to treat soil impacts not removed via excavation (i.e., B8) through in situ injections. The expansion of in situ groundwater remediation in Alternatives 5, 6, and Alternative 7 do not increase the protectiveness of the remedy as there is no additional risk associated with the groundwater that is being treated.

8.2.2 Permanence

Permanence is a factor by which the cleanup action alternative permanently reduces the toxicity, mobility, or volume of hazardous substances. It takes into account the adequacy of the alternative in destroying the hazardous substances, the reduction or elimination of hazardous substance releases and sources of releases, the degree of irreversibility of the waste-treatment process, and the characteristics and quantity of treatment residuals generated. Removal of soil would be considered the most permanent soil action because it would permanently eliminate the source of releases at the Property. Alternatives 2 through 7 include soil removal; however, it is not feasible to permanently remove all groundwater contamination because low pumping rate for the upper terrace deposits and large area of contaminant plume migration. Therefore, the permanence of all alternatives depends on the longevity of institutional controls and monitoring and the extent of groundwater treatment. Alternatives 3, 4, 5, 6, and 7 have additional groundwater treatment, potentially lessening the need for institutional controls on groundwater. The alternatives are ranked based on the extent of soil removal and groundwater remediation in order least to most permanent: Alternative 2, Alternative 3, Alternatives 4 and 5, Alternatives 6 and 7.

8.2.3 Effectiveness over Long Term

Long-term effectiveness includes the degree of certainty that the alternative will be successful; the reliability of the alternative for the expected duration of hazardous substances remaining on site at concentrations that exceed CULs; the magnitude of residual risk with the alternative in place; and the effectiveness of controls required to manage treatment residues or remaining wastes. Alternative 7 is considered most effective, with Alternative 6 closely ranked behind, over the long term in addressing groundwater contamination. Alternatives 4 and 5 are ranked slightly lower than Alternative 6. Alternative 3 addresses the highest areas of the groundwater contamination via bioremediation but not the entirety, resulting in a slightly less effective alternative than Alternatives 4 and 5. Alternative 2 is ranked lower, as no active groundwater remediation is incorporated.

8.2.4 Management of Short-Term Risks

Short-term risks to remediation workers, the public, and the environment are assessed under this criterion. Generally, short-term risks are expected to be linearly related to the amount of material handled, treated, and/or transported and disposed of (e.g., worker injury per cubic yard excavated [equipment failure], public exposure per cubic yard-mile transported [highway accident]).

This factor addresses the risk to human health and the environment associated with the alternative during construction and implementation, and the effectiveness of measures that will be taken to manage such risks. Potential public exposure during transport, handling, and excavation required for

the alternatives could lead to short-term risks. Alternative 3 best facilitates the management of short-term risks, as it includes only shallow soil removal and handling and Source Area injections. Alternatives 2, 4, 6, and 7 include the deeper soil removal and handling, but the deeper extent includes saturated soil with increased shoring and dewatering. Alternatives 5, 6 and 7 also involve drilling in the right-of-way. Alternative 3 is ranked highest, as the active remediation is concentrated in the Source Area and the risks can be controlled accordingly. Alternative 7 is ranked lowest, based on both the deeper soil excavation and extensive injections along public rights-of-way, resulting in slightly higher potential risk to remediation workers and the public.

8.2.5 Technical and Administrative Implementability

This factor addresses whether the alternative can be implemented and is technically possible. The availability of necessary materials, regulatory requirements, scheduling, access for construction operations and monitoring, and integration with existing and neighboring site uses must be considered. The deeper soil removal for Alternatives 2, 4, 6 and 7 reduces the implementability. Alternatives 5, 6, and 7 include the implementation issues associated with injection in the right-of-way in a residential neighborhood.

8.2.6 Public Concerns

This factor includes considering concerns from individuals, community groups, local governments, tribes, federal and state agencies, and any other organization that may have an interest in or knowledge of the Site and that may have a preferred alternative. Through the public process, the public will have an opportunity to review and comment on plans.

8.3 Disproportionate-Cost Analysis

In accordance with WAC 173-340-360(3)(e), the most practicable permanent solution evaluated will be the baseline cleanup action alternative to which the other cleanup action alternatives are compared. Based on this, Alternative 7 is the baseline alternative for this analysis. Table 8-1 summarizes the comparative analysis, with the alternatives' cost estimates shown in Tables 7-2 through 7-7. Each alternative was given a rating between 1 and 5 (5 being optimal, 1 being inadequate). Where there were only slight differences, fractional ratings were applied.

Based on these criteria, Alternative 2 has a rating of 2.6; Alternative 3, 4; Alternative 4, 3.5; Alternative 5, 3.3; Alternative 6, 3.2; and Alternative 7, 3.2 (see Table 8-1). Alternative 3 has the highest average rating of evaluation factors. Comparing the cost, Alternative 3 is nearly \$3M less expensive than the most permanent alternative, Alternative 7. Additionally, the environmental benefit in either removing more soil (Alternatives 2, 4, 6, and 7) or remediating a larger plume (Alternatives 5, 6, and 7) is marginal, as the contamination is relatively stable and there is no practical environmental risk in the residual contamination based on use, lack of potability, and soil and groundwater concentrations. Further, in situ groundwater treatment will likely result in ancillary treatment of soil contamination beneath the water table, reducing the benefit to excavate deeper soil. A comparison of the above factors with the estimated cost for each alternative shows that Alternative 3 balances the benefits with the costs associated for implementation of the alternative.

9 RECOMMENDATION

Alternative 3 addresses the soil above CULs by removing shallow contamination. It also removes the source area for groundwater and deeper soil contamination via enhanced bioremediation. Alternative 3 is protective because extensive investigation of the Site showed that there was no threat to human health or the environment through the groundwater pathway from drinking, through discharge to surface water, or through possible exposure to indoor air. Source removal and reduction through excavation and in situ bioremediation will remove contamination and also remove the source of groundwater contamination.

The recommended Alternative 3 has a reasonable restoration timeframe based on the factors identified in WAC 173-340-360(4). The potential risks to human health and the environment posed by the Site are limited to soil, which will be addressed following implementation of the remedy to six feet bgs. The implementation, both excavation and injections, is estimated to be several months. An alternative that includes deeper excavation would result in full soil removal to 15 feet bgs and a slightly shorter restoration timeframe, however excavation would require a longer implementation timeframe due to shoring, dewatering and associated groundwater treatment. The current and future use of the Site and surrounding areas are expected to remain a mix of commercial and residential; resources are not affected by releases from the Site, following soil remediation.

As discussed in Section 6.1.2 above, alternative water supplies are available and the upper WBZ in the Source Area has been determined to be nonpotable. Institutional controls will be kept as an additional measure for groundwater impacted on the Property which will remain with the land and will be effective and reliable. Ongoing monitoring will provide the ability to monitor migration of hazardous substances on Site. Additionally, the source area will be removed by Alternative 3, significantly reducing the hazardous substances at the Site; and the dilution of groundwater concentrations in the plume have been documented. Further, groundwater use on the Port property will be prohibited by an environmental covenant.

The cost for Alternative 3 is reasonable for the amount of environmental benefit and comparative lack of environmental risk posed by the Site as demonstrated through extensive Site characterization.

LIMITATIONS

The services undertaken in completing this report were performed consistent with generally accepted professional consulting principles and practices. No other warranty, express or implied, is made. These services were performed consistent with our agreement with our client. This report is solely for the use and information of our client unless otherwise noted. Any reliance on this report by a third party is at such party's sole risk.

Opinions and recommendations contained in this report apply to conditions existing when services were performed and are intended only for the client, purposes, locations, time frames, and project parameters indicated. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations subsequent to performance of services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this report.

Table 2-2
Historical Volatile Organic Compounds in Soil (ug/kg)
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington

NOTES:

Bold values indicate detections that exceed one or more of the screening criteria.

-- = not analyzed.

CUL = cleanup level.

feet bgs = feet below ground surface.

J = estimated concentration.

MTCA = Model Toxics Control Act.

NV = no value.

U = not detected at or above method reporting limit.

ug/kg = micrograms per kilogram.

UR = rejected non-detect because of very low matrix spike/matrix spike duplicate or laboratory control standard recovery.

^aValues calculated using toxicological data and standard Method B groundwater CULs for total xylenes, as not all data were available for individual m,p- and o-xylenes.

Table 2-3
Historical Volatile Organic Compounds in Groundwater (ug/L)
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington

NOTES:

Bold values indicate detections that exceed one or more screening criteria.

-- = not analyzed.

CUL = cleanup level.

feet bgs = feet below ground surface.

J = estimated concentration.

MTCA = Model Toxics Control Act.

NA = not available.

NV = no value.

U = not detected at or above method reporting limit.

ug/L = micrograms per liter.

UR = rejected non-detect because of very low matrix spike/matrix spike duplicate or lab control standard recovery.

UWBZ = upper water-bearing zone.

^aTotal xylenes value.

**Table 3-1
Monitoring Schedule
Former Park Laundry Site
Union Ridge Investment Company
Ridgefield, Washington**

NOTES:

During sampling event, samples from MW05 will be duplicated.

Monitoring wells sampled quarterly were sampled in March, June, September, and December.

Monitoring wells sampled semiannually to be sampled in March and September.

MW = monitoring well.

NA = not applicable.

^aSampled every 18 months in March and September.

^bMonitoring well sampled by Port of Ridgefield.

^cSampled every 18 months in January and August, beginning August 2016.

NOTES:

All MTCA Method A CULs and Method B CULs for 1,1-dichloroethene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, and vinyl chloride are from Ecology July 2015 CLARC data tables. MTCA Method B CULs for TCE and PCE are from Ecology May 2015 CLARC guidance document.

Non-detect results are not evaluated against CULs.

Shaded results indicate exceedance of MTCA Method A CULs.

-- = not detected at or above method reporting limits.

bgs = below ground surface.

CLARC = Cleanup Levels and Risk Calculation.

CUL = cleanup level.

Ecology = Washington State Department of Ecology.

J = estimated value.

MTCA = Model Toxics Control Act.

NV = no value.

PCE = tetrachloroethene.

TCE = trichloroethene.

ug/kg = micrograms per kilogram.

NOTES:
All MTCA Method A and Method B CULs for 1,1-dichloroethene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, and vinyl chloride are from Ecology July 2015 CLARC data tables. MTCA Method B CULs for TCE and PCE are from Ecology May 2015 CLARC guidance document.
Bold results indicate exceedance of MTCA Method B CULs.
Non-detect results are not evaluated against CULs.
Shaded results indicate exceedance of MTCA Method A CULs.
bgs = below ground surface.
CLARC = Cleanup Levels and Risk Calculation.
CUL = cleanup level.
Ecology = Washington State Department of Ecology.
J = Result is an estimated value.
MTCA = Model Toxics Control Act.
NV = no value.
PCE = tetrachloroethene.
TCE = trichloroethene.
U = not detected at or above method reporting limits.
ug/kg = micrograms per kilogram.
UJ = Result is non-detect and an estimated value.

NOTES:

All MTCA Method A CULs and Method B CULs for 1,1-dichloroethene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, and vinyl chloride are from Ecology July 2015 CLARC data tables. MTCA Method B CULs for TCE and PCE are from Ecology May 2015 CLARC guidance document.

Bold results indicate exceedance of MTCA Method B CULs.

Shaded results indicate exceedance of MTCA Method A CULs.

-- = not detected at or above method reporting limits.

bgs = below ground surface.

CLARC = Cleanup Levels and Risk Calculation.

CUL = cleanup level.

Ecology = Washington State Department of Ecology.

MTCA = Model Toxics Control Act.

NV = no value.

PCE = tetrachloroethene.

TCE = trichloroethene.

ug/L = micrograms per liter.

^aMTCA Method B result is value associated risk for cancer.

NOTES:

All MTCA Method A and Method B CULs-for 1,1-dichloroethene, cis-1,2-dichloroethene, trans-1,2-dichloroethene, and vinyl chloride are from Ecology July 2015 CLARC data tables. MTCA Method B CULs for TCE and PCE are from Ecology May 2015 CLARC guidance document.

Bold results indicate exceedance of MTCA Method B CULs.

Non-detect results are not evaluated against CULs.

Shaded results indicate exceedance of MTCA Method A CULs.

bgs = below ground surface.

CLARC = Cleanup Levels and Risk Calculation.

CUL = cleanup level.

Ecology = Washington State Department of Ecology.

MTCA = Model Toxics Control Act.

NV = no value.

PCE = tetrachloroethene.

TCE = trichloroethene.

U = not detected at or above the method reporting limit.

ug/L = micrograms per liter.

¹MTCA Method B result is value associated risk for cancer.

Table 4-2
Volatile Organic Compounds in Groundwater
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington

NOTES:

Bold text indicates that value exceeds MTCA Method A screening levels.

-- = not analyzed.

bgs = below ground surface.

CLARC = cleanup levels and risk calculation.

J = estimated value.

MTCA = Model Toxics Control Act.

MTCA Method A = MTCA standard method A groundwater screening level values.

MTCA Method B = MTCA standard method B groundwater screening level values for noncarcinogenic compounds.

NV = no value.

PCE = tetrachloroethene.

TCE = trichloroethene.

U = not detected at or above the method reporting limit (2011) or method detection limit (2012 on).

ug/L = micrograms per liter.

UJ = Analyte estimated, not detected at or above the method reporting limit (2011) or method detection limit (2012 on). Reported detection limit is approximate and may or may not represent actual limit of quantitation necessary to accurately and precisely measure analyte in sample.

UR = Analyte not detected above detection limit; result rejected.

^aSample collected approximately 1 foot from bottom of well.

^bMTCA standard Method B screening level values for PCE and TCE are based on State of Washington CLARC guidance dated September 2012 and on Washington Administrative Code 173-340-720 (7)(b).

NOTES:
 During sampling event, samples from MW05 will be duplicated.
 Monitoring well MW47D is currently sampled by the Port of Ridgefield on an 18-month schedule, and the results will be incorporated into Park Laundry monitoring reports.
 For groundwater monitoring events conducted every 18 months, monitoring wells will be sampled during alternating dry (September) and wet (March) seasons.
 MW = monitoring well.

**Table 7-2: Cost Estimate
Alternative 2: Soil Excavation to 15', Institutional Controls, and
Groundwater Monitoring
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington**

Remedy Components

- 1 Excavate to clay layer (appx. 15 ft bgs).
- 2 Backfill with clean, imported material.
- 3 Institutional controls, including groundwater prohibition.
- 4 Groundwater monitoring.

Assumptions

- 1 Density of soil = 1.6 tons/CY.
- 2 1,000 CY of impacted soil will be removed and disposed of.
- 3 Excavation extent shown in Figure 7-2.
- 4 Excavated material will be characterized prior to off-site disposal. It is assumed that material will be hazardous and disposed of at a Subtitle C landfill (Chemical Waste Management, Arlington, OR). Estimated cost based on 2017 bid prices.
- 5 One waste characterization sample and ten confirmation samples will be taken at the excavation.
- 6 Water from dewatering excavation will be pretreated on site and transported to publicly owned sanitary sewer facility for discharge.
- 7 Remedial excavations will be backfilled with clean, imported material and compacted to a minimum of 92%, based on the Modified Proctor Test (ASTM, 2012).
- 8 Surface restoration will be completed with gravel or asphalt to match previous conditions.
- 9 Groundwater monitoring will be conducted every 18 months. Wells to be monitored include the source area (MW03, MW04, MW05, and MW06) and downgradient wells (MW07, MW09, MW10, MW11, MW13, MW15, MW16). Thirty years of groundwater monitoring is assumed. Monitoring wells will be decommissioned in year 30, pending four consecutive clean sampling events.
- 10 Discount rate of 0.7% will be used for calculating the net present value of monitoring costs.
- 11 A 30% contingency rate of the remedial action and professional services subtotal will be used for estimating overall costs.

Groundwater Monitoring
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington**

NOTES:

ASTM = American Society for Testing and Materials.

bgs = below ground surface.

CQA = construction quality assurance.

CY = cubic yards.

EA = each.

ft = feet.

LS = lump sum.

Table 7-3: Cost Estimate
Alternative 3: Soil Excavation to 6', Focused Groundwater Remediation, Institutional
Controls, and Groundwater Monitoring
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington

Remedy Components

- 1 Excavate surface soil (up to 6 feet bgs).
- 2 Backfill with clean, imported material.
- 3 Targeted groundwater remediation near MW01 and MW03.
- 4 Institutional controls, including groundwater prohibition.
- 5 Groundwater monitoring.

Assumptions

- 1 Density of soil = 1.6 tons/CY.
- 2 250 CY of impacted soil will be removed and disposed of.
- 3 Excavation extent shown in Figure 7-2.
- 4 Excavated material will be characterized prior to off-site disposal. It is assumed that material will be hazardous and disposed of at a Subtitle C landfill (Chemical Waste Management, Arlington, OR). Estimated cost based on 2017 bid prices.
- 5 One characterization sample and up to five confirmation samples will be taken at the excavation.
- 6 Excavation will be above the water table, so no dewatering should be necessary.
- 7 Remedial excavations will be backfilled with clean, imported material and compacted to a minimum of 92%, based on the Modified Proctor Test (ASTM, 2012).
- 8 EHC amendment will be grid-injected around a 9,700-SF area around MW03. Treatment interval is 10 feet, on average from 5 to 15 feet bgs. The Property area will receive a higher concentration of EHC than the remainder of the area. Estimate is 43,450 LB of EHC and 30 L of DHC Inoculum, assuming 70 injections.
- 9 Replacement of monitoring wells compromised during remedy implementation is not included in this cost estimate.
- 10 Surface restoration will be completed with gravel or asphalt to match previous conditions.
- 11 Groundwater monitoring will be conducted twice per year for two years, then every 18 months. Wells to be monitored include MW03, MW05, MW09, MW10, MW11, MW13, MW15, and MW16. Thirty years of groundwater monitoring is assumed. Monitoring wells will be decommissioned in year 30.
- 12 Discount rate of 0.7% will be used for calculating the net present value of monitoring costs.
- 13 A 30% contingency rate of the remedial action and professional services subtotal will be used for estimating overall costs.

Controls, and Groundwater Monitoring
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington

Remedy Components

- 1 Excavate surface soil (up to 6 feet bgs).
- 2 Backfill with clean, imported material.
- 3 Targeted groundwater remediation near MW01, MW03, and MW05.
- 4 Institutional controls, including groundwater prohibition.
- 5 Groundwater monitoring.

Assumptions

- 1 Density of soil = 1.6 tons/CY.
- 2 250 CY of impacted soil will be removed and disposed of.
- 3 Excavation extent shown in Figure 7-2.
- 4 Excavated material will be characterized prior to off-site disposal. It is assumed that material will be hazardous and disposed of at a Subtitle C landfill (Chemical Waste Management, Arlington, OR). Estimated cost based on 2017 bid prices.
- 5 One characterization sample and up to five confirmation samples will be taken at the excavation.
- 6 Excavation will be above the water table; no dewatering is necessary.
- 7 Remedial excavations will be backfilled with clean, imported material and compacted to a minimum of 92%, based on the Modified Proctor Test (ASTM, 2012).
- 8 EHC amendment will be grid-injected around a 28,500-SF area around MW03 and MW05. Treatment depth is 10 feet, on average from 5 to 15 feet bgs. The Property area will receive a higher concentration of EHC than the remainder of the area. Estimate is 128,250 LB of EHC and 67 L of DHC Inoculum, assuming 199 injections.
- 9 Replacement of monitoring wells compromised during remedy implementation is not included in this cost estimate.
- 10 Surface restoration will be completed with gravel or asphalt to match previous conditions.
- 11 Groundwater monitoring will be conducted twice per year for two years, then every 18 months. Wells to be monitored include MW03, MW05, MW09, MW10, MW11, MW13, MW15, and MW16. Thirty years of groundwater monitoring is assumed. Monitoring wells will be decommissioned in year 30.
- 12 Discount rate of 0.7% will be used for calculating the net present value of monitoring costs.
- 13 A 30% contingency rate of the remedial action and professional services subtotal will be used for estimating overall costs.

Table 7-7: Cost Estimate
Alternative 7: Soil Excavation to 15', Complete Groundwater Remediation, Institutional Controls, and Groundwater Monitoring
Former Park Laundry
Union Ridge Investment Company
Ridgefield, Washington

Remedy Components

- 1 Excavate to clay layer (approx. 15 feet bgs).
- 2 Backfill with clean, imported material.
- 3 Targeted groundwater remediation near MW01, MW03, and MW05.
- 4 Reactive zone treatment along Main St., Mill St., and N. 1st Ave. with EHC Liquid Amendment.
- 5 Institutional controls, including groundwater prohibition.
- 6 Groundwater monitoring.

Assumptions

- 1 Density of soil = 1.6 tons/CY.
- 2 1,000 CY of impacted soil will be removed and disposed of.
- 3 Excavation extent shown in Figure 7-2.
- 4 Excavated material will be characterized prior to off-site disposal. It is assumed that material will be hazardous and disposed of at a Subtitle C landfill (Chemical Waste Management, Arlington, OR). Estimated cost based on 2017 bid prices.
- 5 One characterization sample and ten confirmation samples will be taken at the excavation.
- 6 Water from dewatering excavation will be pre-treated onsite, and transported to publicly owned sanitary sewer facility for discharge.
- 7 Remedial excavations will be backfilled with clean, imported material and compacted to a minimum of 92%, based on the Modified Proctor Test (ASTM, 2012).
- 8 EHC amendment will be grid-injected around a 26,000-SF area around MW 03 and MW05. Treatment depth is 10 feet, on average from 5 to 15 feet bgs. The Property area will receive a higher concentration of EHC than the remainder of the area. Estimate is 128,250 LB of EHC and 67 L of DHC Inoculum, assuming 199 injections.
- 9 EHC Liquid Amendment will be used along available rights-of-way. 178,000 LB of amendment, 380 liters of DHC Inoculum, and 10,000 LB of pH buffer will be injected in 500 locations.
- 10 Replacement of monitoring wells compromised during remedy implementation is not included in this cost estimate.
- 11 Surface restoration will be completed with gravel or asphalt to match previous conditions.
- 12 Groundwater monitoring will be conducted twice per year for two years, then every 18 months. Wells to be monitored include MW03, MW05, MW09, MW10, MW11, MW13, MW15, and MW16. Thirty years of groundwater monitoring is assumed. Monitoring wells will be decommissioned in year 30.
- 13 Discount rate of 0.7% will be used for calculating the net present value of monitoring costs.
- 14 A 30% contingency rate of the remedial action and professional services subtotal will be used for estimating overall costs.

PCE Concentrations
in Soil (0-15 ft bgs)

Former Park Laundry
 Union Ridge Investment Company
 Ridgefield, Washington

Legend

- Boring Location
- Surface (0.5 ft bgs) Exceedance
- Mid-Depth (5 ft bgs) Exceedance
- Deep (> 12 ft bgs) Exceedance
- Property Boundary

Notes:

1. An exceedance is defined as a concentration in excess of the MTCA Method A cleanup level. MTCA Method A = 50 ug/kg.
2. PCE = tetrachloroethene.
3. ft bgs = feet below ground surface.
4. MTCA = Model Toxics Control Act.
5. ug/kg = micrograms per kilogram.

Water Right Claims Registration

Water Right Claim

Name George C. Oldham

(Short Form) 27

Address P.O. 92 (505 Maple)

Ridgefield, Wa. Zip Code 98642

Phone No. 887-3939

1) Source from which the right to take and make use of water is claimed: Surface Water Ground Water
If surface water, please indicate source; give name if known:

Spring - in Gee Creek drainage area
(River, stream, lake, pond, spring, etc.)

2) Purpose(s) for which water is used:

Domestic Stockwatering Irrigation (lawn and garden) Other Use (specify) _____

3) Legal description of lands on which water is used Lot 16 of James Carty Sr.
Donation Land Claim, located in S.W. 1/4 of
N.W. 1/4, of N.W. 1/4 of S. 19, R. 1 E. of W.M.
T. 4 N.

If located within the limits of a recorded platted property: Town of Ridgefield
Lot 16 Block — of James Carty Sr. D.L.C.
(Give name of plat or addition)

In addition, please indicate Sec. 19 T. 4 N. R. 1 E W.W.M.

County in which lands are located Clark

DO NOT USE THIS SPACE

The filing of a statement of claim does not constitute an adjudication of any claim to the right to use of waters as between the water use claimant and the state or as between one or more use claimants and another or others. This acknowledgment constitutes receipt for the filing fee

Date Registered _____ This has been assigned
Water Right Claim Registry No.

00213045348

Director, Department of Ecology

I hereby swear that the above information is true and accurate to the best of my knowledge and belief.

George C. Oldham

Date 31-October-1973

If claim filed by designated representative print or type full name and mailing address of agent below.

\$2.00 Filing Fee Enclosed

Additional information relating to water quality and/or well construction is available.

A FEE OF \$2.00 MUST ACCOMPANY THIS WATER RIGHT CLAIM

Well No. 7 is eight inches in diameter and was drilled to a depth of 195 feet below land surface. A well log is on file.

DEVELOPMENT SCHEDULE

BEGIN PROJECT BY THIS DATE:	COMPLETE PROJECT BY THIS DATE:	WATER PUT TO FULL USE BY THIS DATE:
Started	Completed	April 1, 1990

PROVISIONS

Installation and maintenance of an access port as described in Ground Water Bulletin No. 1 is required. An air line and gauge may be installed in addition to the access port.

The quantity appropriated by this document is considered to be a portion of the amount reserved by the adoption of Chapter 173-592, the Reservation of Future Public Water Supply for Clark County. The priority date of this permit is August 13, 1986.

"The annual quantity of 241 acre-feet per year authorized herein is totally supplemental to existing rights. No more than 369 acre-feet per year may be withdrawn under all existing recorded and vested water rights enjoyed by the City of Ridgefield."

This permit shall be subject to cancellation should the permittee fail to comply with the above development schedule and/or fail to give notice to the Department of Ecology on forms provided by that Department documenting such compliance.

The Department of Ecology does NOT Warranty the Data and/or the Information on this Well Report.

Depth (feet, BGS)	Well Details	Interval	Percent Recovery	Collection Method	Sample Data			Lithologic Column	Soil Description
					Number	Name (Type)	Blows/6"		

Total depth: 20.0 feet below ground surface.

Borehole completion details

0 to 20.0 feet bgs: 2-inch borehole.

0 to 1.0 feet bgs: Concrete.

1.0 to 5.95 feet bgs: Bentonite chips hydrated with potable water.

5.95 to 13.25 feet bgs: Filter pack sand.

13.25 to 20.0 feet bgs: Sluff.

Well Completion Details

0 to 1.0 feet bgs: Monument.

0.5 to 7.95 feet bgs: 2-inch diameter, PVC, schedule 40, flush threaded, blank riser.

7.95 to 12.95 feet bgs: 2-inch diameter, PVC, schedule 40, flush threaded, 0.010-inch machine slotted, well screen.

12.95 to 13.25 feet bgs: 2-inch diameter, PVC, schedule 40, flush threaded, end cap.

NOTES: 1) TOC = Top of casing. 2) GP = Geoprobe. 3) bgs = Below ground surface.

Water level 4.42 feet below TOC measured after well installation.

Hydrology/Level Measurements

Date	Time	DT-Bottom	DT-Product	DT-Water	(Product Thickness)	(Water Column)	(Gallons/ft x Water Column)
					DTP-DTW	DTB-DTW	Pore Volume

(0.75" = 0.023 gal/ft) (1" = 0.041 gal/ft) (1.5" = 0.092 gal/ft) (2" = 0.163 gal/ft) (3" = 0.367 gal/ft) (4" = 0.653 gal/ft) (6" = 1.469 gal/ft) (8" = 2.611 gal/ft)

Water Quality Data

Purge Method	Time	Purge Vol (gal)	Flowrate l/min	pH	Temp (C)	E Cond (uS/cm)	DO (mg/L)	ORP	Turbidity
(2) Peristaltic Pump									
Final Field Parameters	11:55:00 AM	3.25	1	7.02	12.34	231	8.7	-1.2	83.6

Methods: (1) Submersible Pump (2) Peristaltic Pump (3) Disposable Bailer (4) Vacuum Pump (5) Dedicated Bailer (6) Inertia Pump (7) Other (specify)

Water Quality Observations:

Slightly turbid.

Sample Information

Sampling Method	Sample Type	Sampling Time	Container Code/Preservative	#	Filtered
(2) Peristaltic Pump	Groundwater	11:55:00 AM	VOA-Glass	3	No
			Amber Glass		
			White Poly		
			Yellow Poly		
			Green Poly		
			Red Total Poly		
			Red Dissolved Poly		
			Total Bottles	3

General Sampling Comments

Pressure built up inside well, popped cap off when loosened.
First two attempts had noticeable sediments in bailer. Three attempts at sampling with clean bailer and string each time.

General Sampling Comments

08:32 - Well pumped dry. Slowed pump rate down to lowest level, well not recharging fast enough to sustain any pumping. 2.0 total gallons purged. Collected sample at 1415, 6/20/2012.

General Sampling Comments

Well pumped dry after approximately 2.0 gallons, at 12:10 on 4/8/2013. Came back to well after 24 hours to sample.

Methods: (1) Submersible Pump (2) Peristaltic Pump (3) Disposable Bailer (4) Vacuum Pump (5) Dedicated Bailer (6) Inertia Pump (7) Other (specify)

Water Quality Observations:

Cloudy and tan during purging.
Sample is slightly cloudy with a yellow/tan tint.

Sample Information

Sampling Method	Sample Type	Sampling Time	Container Code/Preservative	#	Filtered
(3) Disposable Bailer	Groundwater	3:35:00 PM	VOA-Glass	5	No
			Amber Glass		
			White Poly		
			Yellow Poly		
			Green Poly		
			Red Total Poly		
			Red Dissolved Poly		
			Total Bottles	5	

General Sampling Comments

Used Oakton for E Cond. YSI used for remaining parameters.
At 14:40: Turbidity units are in AU instead of NTU.
At 14:52: Discovered tubing is not at bottom of well. Replace tubing; inlet at bottom of well.

Sample Information

Sampling Method	Sample Type	Sampling Time	Container Code/Preservative	#	Filtered
(3) Disposable Bailer	Groundwater	3:08:00 PM	VOA-Glass	7	No
			Amber Glass		
			White Poly	1	No
			Yellow Poly		
			Green Poly	1	No
			Red Total Poly		
			Red Dissolved Poly		
			Total Bottles	9	

General Sampling Comments

Green poly is preserved with NaOH and Zinc Acetate.
Air bubbles observed in purge line and flow through cell at the time of the first field parameter.
Oakton used for pH and conductivity readings.
Ferrous Iron = 0.25 mg/L.

General Sampling Comments

PDX P-PUMP SM #1 powered by V2 van inverter.
 PDX Oakton #4 for pH.
 PDX Turb #3 for turbidity.
 PDX YSI #1 for all other parameters.
 Air bubbles observed in flow-thru cell during the final three parameters may have influenced DO readings.

Sampling Event	September 2015	Sample Name	MW10-091715		
Sub Area	MW	Sample Depth	29		
FSDS QA:	BTF 10/20/2015	Easting		Northing	
				TOC	

Hydrology/Level Measurements

Date	Time	DT-Bottom	DT-Product	DT-Water	(Product Thickness)	(Water Column)	(Gallons/ft x Water Column)
					DTP-DTW	DTB-DTW	Pore Volume
9/14/2015	9:34	29.53		12.98		16.55	2.7

(0.75" = 0.023 gal/ft) (1" = 0.041 gal/ft) (1.5" = 0.092 gal/ft) (2" = 0.163 gal/ft) (3" = 0.367 gal/ft) (4" = 0.653 gal/ft) (6" = 1.469 gal/ft) (8" = 2.611 gal/ft)

Water Quality Data

Purge Method	Time	Purge Vol (gal)	Flowrate l/min	pH	Temp (C)	E Cond (uS/cm)	DO (mg/L)	ORP	Turbidity
(2) Peristaltic Pump	11:29:00 AM	2.7	0.6	6.72	14.33	168	1.63	29.2	3.68
	11:42:00 AM	5.4	0.6	6.72	14.15	169	1.1	22.5	1.17
Final Field Parameters	12:02:00 PM	8.1	0.6	6.71	14.13	168	0.91	15.9	1.17

Methods: (1) Submersible Pump (2) Peristaltic Pump (3) Disposable Bailer (4) Vacuum Pump (5) Dedicated Bailer (6) Inertia Pump (7) Other (specify)

Water Quality Observations:

Clear and colorless.

Sample Information

Sampling Method	Sample Type	Sampling Time	Container Code/Preservative	#	Filtered
(3) Disposable Bailer	Groundwater	12:02:00 PM	VOA-Glass	5	No
			Amber Glass		
			White Poly		
			Yellow Poly		
			Green Poly		
			Red Total Poly		
			Red Dissolved Poly		
			Total Bottles	5	

General Sampling Comments

PDX P-PUMP LG #1 powered by V2 van inverter.
 PDX Oakton #4 for pH.
 PDX Turb #3 for turbidity.
 PDX YSI #1 for all other parameters.
 Rainstorm begins during final parameter. Shut well to protect it. Did not get final flowrate or turbidity.

RE: URIC / 8006.31.01
Dear Alan Hughes:

Order No.: 1003038

Specialty Analytical received 99 samples on 3/4/2010 for the analyses presented in the following report.

REVISED REPORT VERSION 2 . Please see case narrative for information on revision.

There were no problems with the analysis and all data for associated QC met EPA or laboratory specifications except where noted in the Case Narrative, or as qualified with flags. Results apply only to the samples analyzed. Without approval of the laboratory, the reproduction of this report is only permitted in its entirety.

Cindy Hillyard
Project Manager

Technical Review

Specialty Analytical**Date:** 23-Nov-10

CLIENT: Maul, Foster & Alongi
Project: URIC / 8006.31.01
Lab Order: 1003038**CASE NARRATIVE**

Report Revision 2.

At the request of the client, the full list of compounds for EPA 8260B are reported.

Report Revision 1.

Per clients request, additional analysis was performed.

Qualifiers: ND - Not Detected at the Reporting Limit
J - Analyte detected below quantitation limits

S - Spike Recovery outside accepted recovery limits
R - RPD outside accepted recovery limits

B - Analyte detected in the associated Method Blank

KEY TO FLAGS

Rev. May 12, 2010

- A This sample contains a Gasoline Range Organic not identified as a specific hydrocarbon product. The result was quantified against gasoline calibration standards
- A1 This sample contains a Diesel Range Organic not identified as a specific hydrocarbon product. The result was quantified against diesel calibration standards.
- A2 This sample contains a Lube Oil Range Organic not identified as a specific hydrocarbon product. The result was quantified against a lube oil calibration standard.
- A3 The result was determined to be Non-Detect based on hydrocarbon pattern recognition. The product was carry-over from another hydrocarbon type.
- A4 The product appears to be aged or degraded diesel.
- B The blank exhibited a positive result great than the reporting limit for this compound.
- CN See Case Narrative.
- D Result is based from a dilution.
- E Result exceeds the calibration range for this compound. The result should be considered as estimate.
- F The positive result for this hydrocarbon is due to single component contamination. The product does not match any hydrocarbon in the fuels library.
- G Result may be biased high due to biogenic interferences. Clean up is recommended.
- H Sample was analyzed outside recommended holding time.
- HT At clients request, samples was analyzed outside of recommended holding time.
- J The result for this analyte is between the MDL and the PQL and should be considered as estimated concentration.
- K Diesel result is biased high due to amount of Oil contained in the sample.
- L Diesel result is biased high due to amount of Gasoline contained in the sample.
- M Oil result is biased high due to amount of Diesel contained in the sample.
- MC Sample concentration is greater than 4x the spiked value, the spiked value is considered insignificant.
- MI Result is outside control limits due to matrix interference.
- MSA Value determined by Method of Standard Addition.
- O Laboratory Control Standard (LCS) exceeded laboratory control limits, but meets CCV criteria. Data meets EPA requirements.
- Q Detection levels elevated due to sample matrix.
- R RPD control limits were exceeded.
- RF Duplicate failed due to result being at or near the method-reporting limit.
- RP Matrix spike values exceed established QC limits; post digestion spike is in control.
- S Recovery is outside control limits.
- SC Closing CCV or LCS exceeded high recovery control limits, but associated samples are non-detect. Data meets EPA requirements.
- * The result for this parameter was greater than the maximum contaminant level of the TCLP regulatory limit.

RE: URIC / 8006.31.01
Dear Alan Hughes:

Order No.: 1003041

Specialty Analytical received 10 samples on 3/4/2010 for the analyses presented in the following report.

REVISED REPORT VERSION 1 . Please see case narrative for information on revision.

There were no problems with the analysis and all data for associated QC met EPA or laboratory specifications except where noted in the Case Narrative, or as qualified with flags. Results apply only to the samples analyzed. Without approval of the laboratory, the reproduction of this report is only permitted in its entirety.

Cindy Hillyard
Project Manager

CASE NARRATIVE

Report Revision 1.

At the request of the client, the full list of compounds for EPA 8260B are reported.

KEY TO FLAGS

Rev. May 12, 2010

- A This sample contains a Gasoline Range Organic not identified as a specific hydrocarbon product. The result was quantified against gasoline calibration standards
- A1 This sample contains a Diesel Range Organic not identified as a specific hydrocarbon product. The result was quantified against diesel calibration standards.
- A2 This sample contains a Lube Oil Range Organic not identified as a specific hydrocarbon product. The result was quantified against a lube oil calibration standard.
- A3 The result was determined to be Non-Detect based on hydrocarbon pattern recognition. The product was carry-over from another hydrocarbon type.
- A4 The product appears to be aged or degraded diesel.
- B The blank exhibited a positive result great than the reporting limit for this compound.
- CN See Case Narrative.
- D Result is based from a dilution.
- E Result exceeds the calibration range for this compound. The result should be considered as estimate.
- F The positive result for this hydrocarbon is due to single component contamination. The product does not match any hydrocarbon in the fuels library.
- G Result may be biased high due to biogenic interferences. Clean up is recommended.
- H Sample was analyzed outside recommended holding time.
- HT At clients request, samples was analyzed outside of recommended holding time.
- J The result for this analyte is between the MDL and the PQL and should be considered as estimated concentration.
- K Diesel result is biased high due to amount of Oil contained in the sample.
- L Diesel result is biased high due to amount of Gasoline contained in the sample.
- M Oil result is biased high due to amount of Diesel contained in the sample.
- MC Sample concentration is greater than 4x the spiked value, the spiked value is considered insignificant.
- MI Result is outside control limits due to matrix interference.
- MSA Value determined by Method of Standard Addition.
- O Laboratory Control Standard (LCS) exceeded laboratory control limits, but meets CCV criteria. Data meets EPA requirements.
- Q Detection levels elevated due to sample matrix.
- R RPD control limits were exceeded.
- RF Duplicate failed due to result being at or near the method-reporting limit.
- RP Matrix spike values exceed established QC limits; post digestion spike is in control.
- S Recovery is outside control limits.
- SC Closing CCV or LCS exceeded high recovery control limits, but associated samples are non-detect. Data meets EPA requirements.
- * The result for this parameter was greater than the maximum contaminant level of the TCLP regulatory limit.

RE: URIC / 8006.31.01
Dear Alan Hughes:

Order No.: 1003049

Specialty Analytical received 90 samples on 3/8/2010 for the analyses presented in the following report.

REVISED REPORT VERSION 1 . Please see case narrative for information on revision.

There were no problems with the analysis and all data for associated QC met EPA or laboratory specifications except where noted in the Case Narrative, or as qualified with flags. Results apply only to the samples analyzed. Without approval of the laboratory, the reproduction of this report is only permitted in its entirety.

Cindy Hilliard

cis-1,2-Dichloroethene	ND	11.1		ug/Kg-dry	1	3/12/2010 10:01:00 PM

Specialty Analytical

Date: 23-Nov-10

CLIENT: Maul, Foster & Alongi
Lab Order: 1003049
Project: URIC / 8006.31.01
Lab ID: 1003049-58

Client Sample ID: GP37-S-12.5
Collection Date: 3/5/2010 10:15:00 AM
Matrix: SOIL
