## **1.0 INTRODUCTION**

This report presents the results of the Phase II environmental site assessment (ESA) for the Port of Everett (Port) North Marina Area. Figure 1 presents the location of the North Marina Area in Everett, Washington with respect to the surrounding vicinity. Figure 2 is a site plan showing the specific properties in the North Marina Area evaluated during the Phase II ESA. The Phase II ESA was completed in support of the North Marina Redevelopment Project (project). The Phase II ESA was performed by Landau Associates for the Everett Maritime LLC (Everett Maritime) and the Port.

The Phase II ESA report is divided into six sections, which contain the following information:

- Section 1.0 describes the objectives of the Phase II ESA and the investigative approach
- Section 2.0 describes the current and historical use of the North Marina Area and the geology and hydrogeology of this area
- Section 3.0 describes the field work associated with the Phase II ESA
- Section 4.0 presents an evaluation of the data collected during the Phase II ESA
- Section 5.0 summarizes the conclusions, and
- Section 6.0 identifies reference materials used in the preparation of this report.

It should be noted that a Phase II ESA was previously conducted for the Everett Shipyard parcel, investigation area “a” on Figure 2, by the Port. As a result, area “a” was not investigated as part of this Phase II ESA. The Everett Shipyard Phase II ESA report should be reviewed for an understanding of investigation area “a” environmental conditions (Landau Associates 2003a).

### **1.1 OBJECTIVES**

The primary objectives of the Phase II ESA are to evaluate the need for environmental cleanup action, and to collect sufficient information to develop a preliminary cost estimate for an appropriate site environmental cleanup. The estimated cost for site cleanup will be presented in a separate document to be submitted to Everett Maritime.

### **1.2 INVESTIGATIVE APPROACH**

Due to the large area and diverse property uses included in the North Marina Area, the Phase II ESA was not intended to identify an exhaustive list of environmental conditions that may warrant limited remedial actions or special consideration during redevelopment activities. Instead, this investigation was

intended to identify potentially significant and widespread environmental impacts, based on the current understanding of present and historical sources and potential sources of contamination.

The Phase II ESA was conducted as a phased investigation involving two rounds of sampling. The first round was conducted to determine whether wide-spread soil or groundwater contamination had occurred as a result of potential sources or activities identified as “high risk issues” in the Phase I ESA (Landau Associates 2001). Some “moderate risk issues” and “low risk issues” identified in the Phase I ESA were also evaluated in the course of determining whether wide-spread soil or groundwater contamination is present in the North Marina Area. The second round of sampling was developed to better characterize contamination identified during the first round and to identify additional potential areas of environmental impacts of specific interest to the Port.

The first round of sampling was conducted on December 22, 23, 29 and 30, 2003 in accordance with the North Marina Area Phase II ESA Work Plan (Landau Associates 2003b). The second round was conducted February 11-13, 2004, with some additional follow-up groundwater sampling later in February and March, in accordance with the Phase II Environmental Site Assessment Work Plan Addendum, North Marina Redevelopment Site (Landau Associates 2004).

## **2.0 NORTH MARINA AREA DESCRIPTION**

This section describes the current and historical property uses of properties in the North Marina Area and presents information regarding the geology and hydrogeology of the area. The North Marina Area is divided into 11 investigation areas for purposes of organization of the Phase II ESA. These investigation areas are shown on the site plan (Figure 2).

### **2.1 CURRENT AND HISTORICAL PROPERTY USE**

This section describes the known current and historical property use of the investigation areas within the North Marina Area.

#### **2.1.1 INVESTIGATION AREA “A”**

Investigation area “a” includes the Everett Shipyard (Fisherman’s Boat Shop), some Everett Engineering buildings, and a portion of the Quality Seafoods facility. As previously discussed, this area was investigated during a separate Phase II ESA for the Port and is not included in the current scope of work.

#### **2.1.2 INVESTIGATION AREA “B”**

The Everett Bayside Marina property and the Port of Everett Property at 1100 13th Street, where records indicate historical use of five underground storage tanks (USTs) (one of which is known to have leaked), are located in investigation area “b”. Boat maintenance has been, and continues to be, conducted in the eastern yard.

#### **2.1.3 INVESTIGATION AREA “C”**

Three properties between 13th and 14th Streets, from the Everett Fire Station #3 location westward to include the Port of Everett Boatyard and the Harbor Marine Maintenance Boat Servicing Center properties, are located in investigation area “c”.

At the Everett Fire Station #3, a UST was reported to have been removed and an active above ground storage tank (AST) exists where the removed UST was located. Harbor Marine Maintenance had reported historical use of multiple chemical products. The Port of Everett Boatyard has been used for general boat maintenance. There is an active UST on the northeast corner of the boatyard with two existing monitoring wells in close proximity.

#### **2.1.4 INVESTIGATION AREA “D”**

Investigation area “d” consists solely of the American Construction Company leasehold, which is involved in pile driving, dredging and marine construction activities, and has operated at this location for approximately 50 years. Historical and current maritime construction activities on the American Construction Company leasehold include, among other things, sandblasting, painting, and storage of creosote-treated timbers. A number of potential sources of spills and/or releases of hazardous chemicals were noted during the Phase I ESA.

#### **2.1.5 INVESTIGATION AREA “E”**

Investigation area “e” is the former location of Puget Sound Truck Lines and Ethyl Corporation, and is currently used by the Port for boat storage. Non-specific documentation suggested that some level of cleanup had occurred upon termination of Ethyl Corporation’s lease, and that USTs used for fuel products during Puget Sound Truck Lines’ use of the property had been excavated and removed from the property. Puget Sound Truck Lines also operated an AST at the site and removed a heating oil UST prior to vacating the property.

#### **2.1.6 INVESTIGATION AREA “F”**

Investigation area “f” includes several properties along the north side of 13th Street (Everett Engineering Building M11, Port overflow parking, Nugget Boat Works, JL Brooks Welding, and the former American Boiler Works). These properties have been used for general industrial and marine industrial purposes.

ASTs and USTs were historically present at properties within investigation area “f”, and the potential presence of a UST at JL Brooks Welding, and an unidentified subsurface structure at Everett Engineering Building M11 remained unconfirmed. Sandblast grit residue and surface soil staining by petroleum product were also noted in some portions of investigation area “f”. Everett Engineering Building M11 and its associated outdoor storage area are characterized by poor housekeeping of general industrial machinery.

#### **2.1.7 INVESTIGATION AREA “G”**

Investigation area “g” is comprised solely of the Ameron International leasehold. A UST was reportedly removed from this area and multiple chemical products are used and stored on this property. The Ameron International leasehold is also the site of a historical fire that destroyed the wood products

mill formerly located at the property. Fires on industrial properties generally have a moderate to high potential to release various hazardous substances.

#### **2.1.8 INVESTIGATION AREA “H”**

Investigation area “h” includes a former US Coast Guard station, the existing Milltown Sailing building, and roadways and parking areas overlying fuel lines and former fuel USTs associated with the marina. The removal of the former USTs and fuel lines and relocation of the new USTs for the marina are considered potential contaminant sources associated with historical activities in investigation area “h”.

#### **2.1.9 INVESTIGATION AREA “I”**

Investigation area “i” is comprised of the property between the 12th Street Waterway and the Ameron International leasehold. This portion of the North Marina Area is currently unused. Anecdotal information indicates that soil land farming for remediation of petroleum hydrocarbon-impacted soil has been performed in this area. Based on the presence of elevated areas within investigation area “i”, it appears that the area has been used for the stockpiling of soil and/or debris.

#### **2.1.10 INVESTIGATION AREA “J”**

Investigation area “j” includes the Marine Spill Response Corporation (MSRC) leasehold. An independent cleanup action was reportedly completed in 1993 to remove material impacted by petroleum hydrocarbons, and potentially other hazardous substances, adjacent to the MSRC facility. Although soil samples indicated that the cleanup action did not leave contaminated material in place, no groundwater samples were collected as part of the cleanup action. Also, an approximately 10,000-gal UST used for fueling Port vehicles, and later for waste oil storage, was reportedly removed in the late 1980s from this area. Although no specific documentation about the decommissioning process was available, this location was identified by Port personnel between the first and second rounds of the Phase II ESA investigations.

#### **2.1.11 INVESTIGATION AREA “K”**

Investigation area “k” includes the Everett Fire Museum where the city maintenance shop was formerly located. Historical activities may have involved the use of fuel products and solvents.

### **2.1.12 JORDAN PARK**

Jordan Park is a small recreational park located between investigation areas “c” and “h”. The park surface is covered by grass and concrete, and several embankments are constructed from fill material of unknown origin.

## **2.2 GEOLOGIC AND HYDROGEOLOGIC DESCRIPTION**

The upper-most soil unit at the North Marina Area consists primarily of fill derived from marine alluvium hydraulically placed over the last 50 to 60 years. Based on information reviewed in the Phase I ESA, wood waste and concrete debris may also be present in the North Marina Area. Sawdust deposits resulting from historical lumber mill operation in the North Marina Area have been identified in nearshore sediments.

According to the United States Department of Agriculture Soil Conservation Service (SCS 1983), the North Marina Area lies within a soil mapping unit area designated as Urban Land. Urban Land is described as nearly level to gently sloping areas covered by streets, buildings, parking lots, and other structures that obscure or alter the soil so that identification is not feasible. The source of much of the Urban Land at the Port appears to be material dredged from the waterway and wood industry byproducts (e.g., sawdust and wood chips) from historic industrial activities.

According to the U.S. Geological Survey (USGS) Geologic Map of the Everett Quadrangle, non-fill native soil along West Marine View Drive consists of Vashon Drift advance outwash (USGS 1985). This soil is described as clean, mostly gray, well stratified, unconsolidated sand with pebbles and some cobbles. Shallow groundwater in the area is believed to have a relatively flat gradient and is estimated to flow generally to the west, with some local flow variations to the north and south near the shorelines. Geologic and hydrogeologic conditions based on the results of the Phase II ESA are presented in Section 4.1.

Tidal influences in the North Marina Area, combined with the flow of the Snohomish River into Port Gardner Bay, have historically contributed to siltation of the waterways and the need for periodic dredging along the Everett waterfront. According to U.S. Army Corps of Engineers (USACE) tidal datum, 1953, the estimated highest and lowest tides are +14.5 ft and -4.5 ft MLLW, respectively (Pentec 1992).

## **3.0 FIELDWORK DESCRIPTION**

This section describes the investigation and sampling procedures employed during the Phase II ESA to evaluate environmental conditions at the site. The primary focus of the phased investigation was to determine soil and groundwater quality characteristics. Additional activities included performing a geophysical survey to determine whether an unconfirmed UST remained onsite and collection of methane gas and groundwater level measurements in anticipation of redevelopment activities. Groundwater level data and access to piezometers were provided to Cornerstone Geotechnical, Everett Maritime's consultant for geotechnical services, for further evaluation. Soil and groundwater sampling locations are shown on Figure 3. Table 1 presents the rationale, sample collection methods, analytical test methods, and other details related to the samples collected during the Phase II ESA.

### **3.1 GEOPHYSICAL SURVEY**

A geophysical survey was used to attempt to locate a UST that was suspected to be present on the JL Brooks Welding property (area "f", Figure 2). A vent pipe, a typical component of USTs, was observed attached to the side of Building M14 at the JL Brooks Welding property. Although the property lessee had no knowledge of any USTs on the property, and no physical signs of USTs in the area were discovered, the presence of a vent pipe and a lack of any information about UST construction or removal at this location warranted further investigation to determine whether a UST remained onsite.

Remote sensing instruments were used to non-intrusively check for the presence of the USTs. Ground penetrating radar, utility locator equipment and a hand-held magnetometer were used to attempt to locate the potentially present UST and any associated fuel lines. The area of interest was evaluated using a grid system on an approximate 4-ft grid interval. Evidence of the presence of a UST or associated piping was not encountered during the geophysical investigation. The results of the geophysical survey are presented in Appendix A.

### **3.2 SOIL SAMPLING**

Soil samples were collected from surficial soils by hand, and were collected from subsurface soil from boring samples using direct push drilling techniques.

Surface soil samples were collected at locations where potential environmental impacts were likely to occur at ground surface, based on the historic activities for that location (e.g., boat maintenance), or at locations where visual evidence of environmental impact was present (e.g., surface staining). The surface soil samples were generally collected from the top six inches of soil using a clean stainless steel spoon. Surface soil sample NMP2-C-5-SS was collected from an area covered by asphalt; therefore, the

sample was collected from the upper six inches below the asphalt and gravel base course layer using a Geoprobe direct push drill rig during the construction of piezometer P4. Fourteen surface soil samples were collected for laboratory analysis during the Phase II ESA. These 14 samples included 3 composite samples collected from 4 soil stockpiles present in investigation area "i".

Subsurface soil samples were collected to bound the vertical extent of shallow soil contamination and to identify the presence of contamination that would likely be present in the vicinity of the groundwater table (e.g., petroleum hydrocarbon contamination). A total of 64 borings were advanced during the Phase II ESA, including the 12 borings advanced for the installation of piezometers.

Boreholes were constructed to depths of four to thirteen feet below ground surface (BGS). Continuous soil samples were collected to the total depth of each boring for geologic logging purposes and field screening for possible contamination. Field screening was accomplished by using a photoionization detector (PID) and visual inspection for discoloration and obvious presence of sheen or non-aqueous phase liquid (NAPL) presence. Fourteen of the subsurface soil samples collected from the borings were tested for chemical constituents during the Phase II ESA. Additional subsurface soil samples submitted to the laboratory were archived for potential future analysis.

Soil from the borings was described using the Uniform Soil Classification (USCS) and field screened for possible contamination. The presence and extent of wood debris were also noted during drilling. The boring logs for borings and piezometers are presented in Appendix B. A clean stainless steel bowl was used to gently homogenize the sample material prior to placement in the proper laboratory supplied sample containers, except for sample portions that were submitted for analysis of volatile organic compounds (VOCs), which were handled with a minimal amount of disturbance to avoid contaminant volatilization out of the samples.

No evidence of gasoline- or diesel-range free phase petroleum hydrocarbon contamination was observed during the Phase II ESA, although a slight petroleum odor was observed in shallow soil in a number of borings. However, evidence of heavy oil or creosote range hydrocarbon contamination was encountered on the American Construction Company parcel (investigation area "d") at locations D-3, D-4 and piezometer P9. The material was encountered within a relatively limited zone at a depth of 4 to 7 ft BGS.

Nineteen of the borings, identified as NMP2-SS-1 through NMP2-SS-19, were completed in investigation area "i" to characterize the soil stockpile areas present. A discolored and odorous layer of material was encountered at NMP2-SS-2, and 15 additional borings were completed within this stockpile area to delineate the lateral and vertical extent of this affected soil layer. The lateral extent of the affected soil layer is shown on Figure 4 and the vertical extent and thickness of the discolored material is presented in Table 2. The discolored material was encountered at 1.2 to 2.1 ft BGS in the borings, and is

between 0.2 and 1.8 ft thick. Material similar in appearance was observed in material stockpiled in investigation area "g", along the fence line that separates investigation areas "g" and "i" in the northwest portion of that property.

A composite sample of the material, NMP2-I-X, was collected to characterize the concentration of chemical constituents in the discolored soil layer. Composite soil sample NMP2-I-Y was collected from the soil layer directly below the discolored material to determine if the discolored material had affected underlying soil. Both composite soil samples were collected from boreholes NMP2-SS-5, NMP2-SS-12 and NMP2-SS-14.

### **3.3 GROUNDWATER SAMPLING**

Groundwater samples were collected either directly from the borehole installed by Geoprobe direct push drilling technology, from an installed piezometer (described below), or from pre-existing monitoring wells. This section describes the methodology used in the collection of groundwater samples.

#### **3.3.1 GROUNDWATER SAMPLES FROM BORINGS**

Groundwater samples were collected from 33 boreholes using a peristaltic pump with disposable tubing. A decontaminated temporary well screen was installed in the borehole at the time of sampling to reduce turbidity in the sample volume. Groundwater was over-purged from the borehole prior to sample collection to further reduce turbidity. Field parameters (pH, temperature and conductivity) were measured using a portable meter during purging. Upon completion of purging, the groundwater samples were collected directly into the laboratory-supplied containers.

#### **3.3.2 PIEZOMETER INSTALLATION AND SAMPLE COLLECTION**

Twelve piezometers were installed throughout the North Marina Area during the Phase II ESA to provide depth to groundwater data for future construction of an underground parking facility, evaluate methane gas presence in the subsurface (described below) and collect groundwater samples to evaluate water quality. Each piezometer was installed using Geoprobe direct push drilling technology. The piezometers were constructed using pre-packed well casings, which include 10/20 Colorado sand filter pack and ¾-inch diameter PVC screen with a 0.020-inch slot size. The piezometers were installed to a depth of 8 to 13 ft BGS, and were typically screened from 3 ft BGS to the bottom of the boring. This piezometer configuration maximized the potential for extending the screen section across the water table to allow the detection of petroleum hydrocarbon free product (if present) and the measurement of

methane in the unsaturated zone from the completed piezometer. Piezometer construction details are presented in Appendix B.

The pieometers were developed prior to groundwater sampling by purging five to ten casing volumes of groundwater from the piezometer using a peristaltic pump and disposable tubing. All piezometers were allowed to stabilize for at least 3 days following development before groundwater samples were collected for chemical analysis. In addition to the piezometers installed for the Phase II ESA, two shallow observation wells, NMW-E and NMW-W, associated with the existing gasoline UST in investigation area “c” were also sampled.

Piezometers were sampled using a peristaltic pump and disposable tubing. All piezometers were purged of at least 3 casing volumes prior to sampling. Samples collected for metals analysis were field filtered using a 45-micron in-line filter.

All piezometers produced sufficient flow to allow sample collection for all analytical parameters, except for P9. Because of slow recharge, P9 could only be sampled for cPAH during the February sampling. As a result, the piezometer was re-sampled in March to collect a sample for dissolved metals analysis.

### **3.4 METHANE GAS MONITORING**

Based on subsurface exploration information provided by the Port and subsurface information collected during this Phase II ESA, significant deposits of wood debris are present at the site. Landau Associates conducted methane gas monitoring during Geoprobe activities and post construction piezometer monitoring to determine whether methane generated from wood debris is likely to be a significant issue for design of pile-supported structures. Monitoring was conducted during boring advancement by periodically monitoring the boring casing with a combustible gas meter. Piezometers were screened across the water table and up into the vadose zone, where feasible, to allow methane gas monitoring in the piezometers following installation.

## **4.0 DATA EVALUATION**

This section presents an evaluation of the physical and chemical data collected in the Phase II ESA. Chemical data are evaluated with respect to the Washington State Model Toxics Control Act (MTCA) regulations.

### **4.1 GEOLOGIC AND HYDROGEOLOGIC CONDITIONS**

Geologic and hydrogeologic conditions were evaluated based on the 52 borings and 12 piezometers installed during the Phase II ESA. In general, encountered site soil conditions consist of 6 to greater than 13 ft of hydraulic fill overlying native silt. Hydraulic fill is typically a loose to medium dense, poorly graded fine to coarse sand or silty sand. Wood debris was present in the hydraulic fill layer in many of the borings. Wood debris presence ranged from small wood fragments intermixed with fill to distinct layers of wood debris.

The locations and depth intervals at which wood debris were encountered are presented in Table 3, and the aerial distribution of wood debris is presented on Figure 5. Based on the distribution illustrated on Figure 5, wood debris is present throughout much of the North Marina Area, although it is most consistently present over the northern half of the site.

Native soil, consisting of medium stiff, gray sandy silt with clay, was encountered in 4 borings (C-7, and H-1, -2, and -3). Depth to native soil at these locations ranged from 6 to 10 ft. At other boring locations, which ranged in depth from 4 to 13 ft BGS, native soil was not encountered.

Groundwater was encountered at the time of drilling at depths ranging from 2.2 to 6.5 ft BGS, as indicated in Table 3. The depth to water was also measured in completed piezometers P1 though P7, with depths ranging from 2.3 to 4.7 ft BGS, as presented in Table 4. The depth to water generally appears to be shallower towards the center of the site and deeper in the vicinity of the shoreline, which is consistent with groundwater flow toward marine surface water. Reference elevations were not established for monitoring wells, so groundwater elevations could not be determined, and groundwater flow characteristics could not be more extensively characterized as part of the Phase II ESA.

### **4.2 METHANE MONITORING**

Methane concentrations were monitored during construction in soil borings completed during the two rounds of sampling, as presented in Table 3 and as shown on Figure 6. Post-construction methane levels were monitored twice in piezometers NMP2-P1 through NMP2-P7 after the subsurface conditions were allowed to equilibrate for at least one week, and the data are presented in Table 5. Maximum detected concentrations of methane in each boring and piezometer are shown on Figure 4.

As shown in Table 3, methane was detected in most of the borings where wood debris was encountered. Methane was detected in 20 of the 45 borings, including piezometers, constructed during the Phase II ESA. At two locations, piezometer P12 and boring B-4, methane concentrations during drilling were detected at concentrations exceeding the lower explosive limit (LEL), which is 5 percent methane, by volume. The LEL is the lowest concentration at which methane would have the potential to explode. However, 20 percent of the LEL (i.e., 1 percent methane, by volume) is typically used as a rule of thumb to identify the potential for an explosive condition to exist.

As shown in Table 5, methane concentrations were detected in three of the seven piezometers, NMP2-P3, NMP2-P6, and NMP2-P7, at levels above the LEL for measurements made after piezometer construction was completed. Methane concentrations observed in these same piezometers during boring completion were less than the LEL, which suggests that the methane levels observed during construction in other non-piezometer borings (Table 3) underestimate the actual methane concentrations when the subsurface is at equilibrium.

In addition to an explosion, the accumulation of methane can deplete the oxygen concentration to an unsafe level, which is a significant issue for confined space entry. These results suggest that subsurface methane accumulations could be a significant issue for design of any subsurface structures that are not properly sealed or ventilated, including utility vaults, parking garages, or pile-supported structures where voids can form beneath the floor slab.

It is likely that methane buildup will be greater under post-construction site conditions because the increase in impermeable surface area resulting from increased paving and building density will tend to allow greater accumulation of methane in subsurface soil gas, subsurface utility vaults, and in any voids that develop beneath pile supported structures.

### **4.3 CHEMICAL DATA**

This section presents the chemical data collected as part of the Phase II ESA and describes the cleanup levels to which these data are compared. Tables 6 and 7 identify the analytical parameters for Phase II ESA soil and groundwater samples, respectively. The analytical results for detected constituents are presented in Tables 8 and 9 for soil and groundwater samples, respectively. Summary tables for all analytical testing parameters for soil and groundwater samples are presented in Appendix C. Original laboratory reports are maintained in the project files.

### **4.3.1 CLEANUP LEVELS**

Based on the redevelopment plans for the North Marina Area, it is expected that the site will be subject to a combination of residential, commercial, and industrial use. MTCA Method B soil cleanup levels for unrestricted land use were determined to be appropriate for protection of these likely future land use scenarios. For constituents that do not have Method B cleanup levels (i.e., TPH and total cPAH), Method A cleanup levels for unrestricted site use were used. Background concentrations of metals are also taken into consideration when comparing detected concentrations to cleanup levels (Ecology 1994). It is expected that human receptors could be exposed to contaminants in surface or subsurface soil by direct contact (incidental ingestion and dermal contact) or exposure to surface water via groundwater impacted by contaminant migration from soil.

Site groundwater is not used as drinking water and, based on the close proximity to the marine waterway and likely hydraulic connection between the groundwater and marine surface water in the North Marina Area, future use of the groundwater as drinking water is not expected. Therefore, ingestion of groundwater is not considered a complete exposure pathway for current or future receptors. Based on this information, groundwater Method B cleanup levels are based on discharge to marine surface water. MTCA Method B surface water cleanup levels are also inclusive of the most conservative levels from state and federal surface water quality standards.

Where available, metals concentrations were also compared to state background concentrations for metals in groundwater (PTI 1989). However, the state background concentration for copper of 8 µg/L was not used because analytical results indicated that site groundwater concentrations for copper were generally not detected at the method reporting limit of 2 µg/L.

### **4.3.2 GROUNDWATER**

Groundwater samples collected during the Phase II ESA were analyzed for TPH, BTEX, cPAHs, SVOCs, dissolved metals, and/or VOCs, as shown in Table 7. VOCs were not detected in any groundwater samples at concentrations exceeding MTCA Method B groundwater cleanup levels protective of marine surface water.

Only one of the nineteen groundwater samples analyzed for TPH contained a concentration exceeding the Method A groundwater cleanup levels. Motor oil-range petroleum hydrocarbons were detected at a concentration of 0.92 mg/L in sample NMP2-B-4-GW, collected near the location of a former UST.

Five of the nine groundwater samples analyzed for cPAHs during the first round of Phase II ESA field activities contained cPAHs at concentrations exceeding cleanup levels. Three of these samples

(NMP2-D-1-GW, NMP2-D-2-GW, and NMP2-D-4-GW) were located in investigation area “d”, one sample (NMP2-F-1-GW) was located in investigation area “f”, and one sample (NMP2-G-2-GW) was located in investigation area “g”. No visible pattern to the locations of groundwater cleanup level exceedances was identified, except for the multiple exceedances in investigation area “d”. Because, cPAHs are not typically found in a dissolved phase in groundwater, it was suspected that the cPAHs detections in groundwater resulted from particulates entrained in the samples during collection rather than being present as dissolved constituents in groundwater.

Based on the cPAH results, groundwater samples collected during the second round of field activities were centrifuged by the lab to remove particulates prior to cPAH analysis. Of the 14 groundwater samples tested for cPAHs during the second round of sampling, only the sample from Piezometer P9 exhibited detectable concentrations of cPAHs, which did not exceed the cleanup level. As presented in Table 9, and as shown on Figure 9, the concentration of total cPAHs detected in the groundwater sample from Piezometer P9 was 0.015 µg/L, compared to the MTCA method A cleanup level of 0.1 µg/L for total cPAHs and the individual Method B cPAH cleanup level of 0.031 µg/L.

The concentrations of cPAHs observed during the second round of investigation suggest that the elevated cPAH levels detected in groundwater samples collected during the first round of sampling were the result of particulate matter influences rather than reflective of actual groundwater quality. It is, therefore, assumed that the detected concentrations of cPAHs in soil are protective of groundwater conditions, with the possible exception of the deeper cPAHs contamination observed in investigation area “d”.

It should be noted that piezometer P9 is located within the area where long chain hydrocarbons (possibly creosote) were observed in investigation area “d”, as described in Section 3.2. These results suggest that the soil contamination at this location is affecting site groundwater in this area, but it does not appear to be causing exceedances of groundwater cleanup levels.

Four of the eighteen groundwater samples analyzed for dissolved metals contained arsenic concentrations exceeding the groundwater cleanup level. The groundwater sample with the highest dissolved arsenic concentration (146 µg/L), was collected from piezometer P9. Piezometer P9 is located in the north yard of the American Construction Company leasehold, where arsenic concentrations of up to 60 mg/kg were detected in subsurface soil at depths of up to 6 ft BGS (as discussed in the following section). Two of the other locations where the groundwater samples exceeded the arsenic groundwater cleanup level (boring F-8 and piezometer P3) were in investigation area “f”, and the fourth location (boring J-2) was located in investigation area “j”. Although arsenic concentrations in subsurface soil at investigation area “f” did not exceed cleanup levels, sandblast grit was identified at ground surface in

some portions of the investigation area. Soil quality samples were not collected from investigation area “j”. Detected concentrations of dissolved arsenic in groundwater are shown on Figure 10.

One of the 18 groundwater samples (NMP2-J-1-GW) analyzed for dissolved metals contained copper at a concentration (4 µg/L) that slightly exceeded the groundwater cleanup level of 2.4 µg/L.

### **4.3.3 SOIL**

Soil samples collected during the Phase II ESA were analyzed for TPH, metals, PCBs, cPAHs, SVOC, and/or BTEX, as shown on Table 6. In general, samples were collected at the ground surface, and at depths of 3 and 6 ft BGS. Typically, samples collected from the 3 ft depth interval were only tested if surface soil samples exceeded a soil cleanup level, and samples collected from the 6 ft depth interval were only tested if the sample collected from the 3 ft depth interval exceeded a soil cleanup level.

TPH, SVOCs, and BTEX were not detected in any Phase II ESA soil sample at concentrations exceeding MTCA Method B cleanup levels protective of direct contact or groundwater.

#### **4.3.3.1 Surface Soil**

Surface soil samples collected during the Phase II ESA were analyzed for TPH, metals, PCBs, cPAHs, BTEX, and/or SVOCs. TPH, BTEX, PCBs, and SVOCs were not detected in any surface soil sample at concentrations exceeding MTCA Method A or Method B cleanup levels protective of direct contact or groundwater.

Ten of the twelve surface soil samples analyzed for metals contained at least one metal at concentrations exceeding MTCA Method B cleanup levels protective of direct contact and/or groundwater (including investigation area “i” stockpiled soil). Metals exceeding cleanup levels protective of surface water include arsenic, cadmium, copper, lead, mercury, and zinc. However, only arsenic and copper were detected at concentrations exceeding the cleanup levels protective of direct contact in investigation areas “c”, “d”, and “f”. Detected concentrations of arsenic in surface soil are shown on Figure 7.

As noted in Section 4.3.2, dissolved metals concentrations observed in the North Marina Area do not exceed groundwater cleanup levels, except for arsenic in investigation areas “d” and “f”, and a single exceedance of the copper groundwater cleanup level in investigation area “j”. Therefore, existing metals concentrations in soil are considered adequately protective of groundwater, except for arsenic, and possibly to a limited extent, copper. In other words, historical leaching of metals from contaminated soils into groundwater has not resulted in concentrations that exceed the groundwater cleanup levels protective of surface water, except for arsenic and possibly copper.

As a result of groundwater dissolved metals results, soil cleanup levels for metals other than arsenic were based on direct contact, while the cleanup level for arsenic considers both direct contact and protection of groundwater. Arsenic equaled or exceeded the soil cleanup level in 7 of the 12 surface soil samples tested for metals, as shown on Figure 7. Other than arsenic, copper was the only metal that exceeded its soil cleanup level for surface soil, and the copper exceedance was at a location (C-4) where arsenic also exceeded the soil cleanup level.

Elevated arsenic concentrations in investigation area "i" appear to be limited to soil stockpiled in that area, although samples were not collected from soil that underlies the stockpiles. Arsenic contamination in one investigation area "i" soil stockpile was encountered in a discrete layer of discolored, odorous material at a depth of 1.3 to 3 ft BGS (sample NMP2-I-X-SS), and a composite sample collected from the soil layer beneath this material (NMP2-I-Y-SS) contained arsenic at a concentration of 5.3 mg/kg. This layer of contaminated material was identified in the borings shown on Figure 4. Arsenic concentrations of 240 mg/kg encountered in the soil and debris in a second stockpile in the northeast corner of investigation area "i" appeared to be more broadly distributed within the stockpile material.

Five of the fourteen surface soil samples analyzed for cPAHs contained cPAH concentrations exceeding cleanup levels protective of direct contact and migration to surface water for either the Method A cleanup level for total cPAH or the Method B criteria for individual cPAHs. Samples with cPAH concentrations exceeding cleanup levels were collected from investigation areas "d" and "f". Detected concentrations of total cPAHs in surface soil are shown on Figure 8. It should be noted that while the total cPAH concentration for the surface soil sample collected from location F-5 did not exceed the criteria, the individual criteria for one cPAH (chrysene) was exceeded.

Similar to metals, the groundwater analytical results indicate that the concentration of cPAHs in soil are adequately protective of groundwater, with the possible exception of contamination observed in subsurface soil in investigation area "d" (as previously discussed). As a result, the cPAHs soil cleanup level is based on direct contact. Four of the 12 surface soil samples tested for cPAHs exceeded the Method A total cPAHs cleanup level of 0.1 mg/kg for unrestricted site use, as shown on Figure 8. Three of these four exceedances occurred in investigation area "d", and the fourth exceedance occurred in investigation area "f".

#### **4.3.3.2 Subsurface Soil**

Subsurface soil samples collected during the Phase II ESA were analyzed for TPH, metals, PCBs, cPAHs, BTEX, and/or SVOCs. BTEX and SVOCs were not detected in any subsurface soil samples at

concentrations exceeding MTCA Method A or Method B cleanup levels protective of direct contact or groundwater.

The concentrations of cPAHs detected in subsurface soil samples collected during the Phase II ESA suggest that the elevated cPAH levels detected in surface soil samples do not extend to significant depth (3 ft BGS, or deeper) at concentrations above the cleanup levels, except for the area where long chain petroleum hydrocarbon contamination was detected in subsurface soil in investigation area "d" (as previously discussed). Detected concentrations of cPAHs in subsurface soil are shown on Figure 11. These detected concentrations are for samples collected from 3 ft BGS, except for samples collected from locations D-3 and D-4, where samples of visibly contaminated soil were collected from about 4 ft BGS.

It should be noted that the cPAH concentration presented on Figure 11 for the piezometer P9 location was collected from 3 ft BGS, and is below the MTCA unrestricted site use Method A cleanup level for total cPAH of 0.1 mg/kg. However, visual evidence of contamination was observed at a depth of 7 ft BGS at this location that would likely exceed the soil cleanup level for cPAHs and possibly TPH; although a sample from this depth was not listed, the results for a sample of similar appearing material from adjacent boring D-4 exceeded the soil cleanup level for cPAH. Thus, the shallow subsurface testing indicates that surface cPAH contamination does not extend to significant depth, but this should not be interpreted to mean that cPAH soil contamination is not present in the areas of observed contamination in investigation area "d" subsurface soil.

Except for investigation area "d", data from subsurface soil samples suggest that metals contamination does not extend to significant depths beneath surface soil. Elevated arsenic concentrations (those exceeding MTCA Method B cleanup levels protective of direct contact and groundwater) in soil sampled in investigation area "d", on the American Construction leasehold, extend to a depth of at least 6 ft BGS, and have significantly impacted groundwater in this area. Detected concentrations of arsenic in surface and subsurface soil collected from the 3-ft depth interval are shown on Figure 12.

Copper concentrations detected in subsurface soil samples from investigation area "c" suggest that the single copper concentration detected in excess of cleanup levels protective of direct contact is a relatively localized occurrence and that it does not extend into subsurface soil.

PCBs were detected at a concentration exceeding the cleanup level protective of surface water in one of the two subsurface soil samples for which PCBs were analyzed. The detection (110 µg/kg Aroclor 1254) occurred at a depth of 3 ft BGS in soil sample NMP2-G-3-CS-3. Although there are no known sources of PCBs at the Ameron site, it is possible that PCBs could have been released to the environment during the historical fire on this property or as a result of other historical site activities. As this was the only detection of PCBs observed during the Phase II ESA, it is expected that PCBs are not a constituent of concern for large portions of the North Marina Area.

## **5.0 CONCLUSIONS AND RECOMMENDATIONS**

The primary objectives of the Phase II ESA was to identify potential environmental conditions that would likely require remedial action in conjunction with redevelopment activities, and whether methane generation resulting from wood debris present in subsurface soil could represent a significant risk of explosion or oxygen depletion in subsurface structures or voids where methane gas could accumulate. To evaluate these conditions, a total of 28 soil samples and 54 groundwater samples were collected and tested for various environmental constituents. Additionally, methane gas was monitored during the advancement of exploration borings and from completed piezometers. Based on the data resulting from these monitoring activities, and observations made during field investigation activities, the following conclusions can be made:

- Wood debris is present in subsurface soil throughout a large portion of the site, and significant methane gas is generated as a result of its presence.
- Concentrations of methane gas exceeded the LEL at a number of monitoring locations, and methane has the potential to accumulate in subsurface structures, voids and vaults at concentrations that pose a risk for explosion or oxygen depletion.
- Although the site has a history of extensive gasoline and diesel use, including numerous USTs, no significant contamination from petroleum hydrocarbons in these product ranges was encountered in soil or groundwater during the Phase II ESA.
- Concentrations of metals and cPAHs exceed cleanup levels protective of human health based on direct contact in surface soil at several portions of the North Marina Area, with arsenic being the only metal detected above its soil cleanup level at multiple locations.
- Soil contamination at the site generally appears to be limited to near-surface soil (within the upper 3 ft), except for deeper arsenic and cPAHs/TPH contamination observed in the north yard of the American Construction Company leasehold (investigation area “d”).
- Arsenic contamination is also present in two soil stockpiles present in investigation area “i”.
- Arsenic exceeded the groundwater cleanup level at four locations; the presence of sandblast grit and/or surface and subsurface soil contamination appear to be contributing influences to the elevated concentrations of arsenic in groundwater.
- A single exceedance of the groundwater cleanup level for copper in investigation area “j” was the only exceedance of the groundwater cleanup levels for metals other than arsenic.
- Single, isolated detections of PCBs and TPH in soil and TPH in groundwater were detected.
- cPAHs exceeded groundwater cleanup levels in a number of groundwater samples collected during the initial round of sampling, but subsequent testing of centrifuged groundwater samples indicates that these exceedances were the result of particulates entrained during the sampling process, rather than dissolved constituents in groundwater.

Based on these conclusions, we recommend the following:

- The potential for methane to accumulate in subsurface structures, and voids that could form beneath pile supported floor slabs and other structures, should be addressed during design.
- Although only one groundwater and one soil exceedance of TPH cleanup criteria were observed during the Phase II ESA, the extensive history of UST presence on the site suggests that localized petroleum hydrocarbon contamination may be encountered during redevelopment activities. Contingency plans should be incorporated into the construction documents to address petroleum hydrocarbons or undocumented USTs, if encountered during construction.
- Arsenic and cPAHs contamination present in shallow soil should be remediated prior to or during site redevelopment. Remediation could consist of excavation and offsite disposal or onsite containment beneath planned pavement or building locations.
- Deeper arsenic contamination in investigation area “d” should be remediated to address arsenic contamination in groundwater at this location. Because of the presence of arsenic contamination in soil below the groundwater table, excavation and replacement with clean fill may be appropriate.
- The presence of long chain petroleum hydrocarbon contamination observed in subsurface soil at multiple locations in investigation area “d” appears to be affecting groundwater quality in piezometer P9, although concentrations of cPAHs did not exceed the groundwater cleanup level at this location. This area may warrant remedial action if additional investigation indicates more elevated groundwater concentrations at other locations.

Excavation and offsite disposal of soil may be needed during construction activities that are planned for the North Marina Redevelopment. Waste materials and contaminated soil must be disposed of at solid waste or hazardous waste landfills, as appropriate. Additionally, the recently promulgated Solid Waste Handling Standards (Chapter 173-350 and the draft Ecology Guidance “Definition of Clean Soils and Dredged Material”, dated January 20, 2004) include an anti-degradation philosophy that appears to restrict how and where excavated soil with levels of contaminants below the cleanup levels may be re-used. A broad coalition of business and government interests are attempting to have these regulations modified because of the significant financial, liability and regulatory issues associated with their present form. But, if enforced as currently written, these regulations may significantly restrict the offsite placement of site soil that is affected by hazardous substances at concentrations below MTCA cleanup levels. The impact of these regulations on the financial, liability and design/construction elements of the project should be considered when planning site grades and the disposition of any excess soil that is intended for offsite re-use.

## 6.0 USE OF THIS REPORT

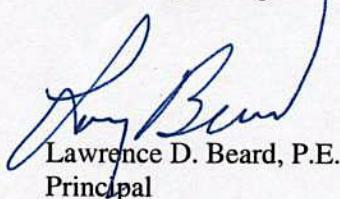

This Phase II ESA report has been prepared for the exclusive use of Everett Maritime LLC and the Port of Everett for specific application to the North Marina Area redevelopment project. No other party is entitled to rely on the information, conclusions, and recommendations included in this document without the express written consent of Landau Associates. Further, the reuse of information, conclusions, and recommendations provided herein for extensions of the project or for any other project, without review and authorization by Landau Associates, shall be at the user's sole risk. Landau Associates warrants that within the limitations of scope, schedule, and budget, our services have been provided in a manner consistent with the level of care and skill ordinarily exercised by members of the profession currently practicing in the same locality under similar conditions as this project. We make no other warranty, either expressed or implied.

We appreciate the opportunity to provide these services to Everett Maritime and the Port. Please contact us if you have any questions or wish to discuss the project further. This document was prepared under the supervision and direction of the following key staff.

ft BGS = Feet below ground surface.

NA = Wood debris not encountered during boring installation.

- a. Wood debris characterized by 1 to 2-inch diameter wood fragments unless otherwise noted.
- b. Depth to water was measured from top of piezometer casings, which are less than 4 inches below ground surface.
- c. Hit refusal at 8.0 feet. Wood chip in cutting shoe.
- d. Small fragments of wood intermixed with soil.
- e. Intermittent wood debris.
- f. No recovery from 5.0-8.0' BGS. However cutting shoe contained wood debris blockage. Also, little resistance to drilling was observed in the 5.0-8.0' BGS interval, suggesting that this interval may consist primarily of decomposed wood debris.
- g. Black wood debris (no odor).

Note: The lower explosive limit is equivalent to 5 percent methane, by volume.

**TABLE 4**  
**POST-CONSTRUCTION GROUNDWATER LEVEL MEASUREMENTS**  
**NORTH MARINA AREA PHASE II ESA**  
**EVERETT, WASHINGTON**

Page 1 of 1

Date	NMP2-P1	NMP2-P2	NMP2-P3	NMP2-P4	NMP2-P5	NMP2-P6	NMP2-P7
1/5/2004	4.59	2.34	4.71	3.22	2.95	4.25	4.32

Note: Depth to groundwater reported as feet below top of piezometer casing. Top of casing positioned less than 4 inches below ground surface.

**TABLE 5**

NA = Not analyzed.

U = Indicates compound was analyzed for, but was not detected at the reported sample detection limit.

J = Result is an estimated value.

(a) Background soil concentrations from Natural Background Soil Metals Concentrations in Washington State (Ecology 1994), unless otherwise noted.

(b) MTCA Method A cleanup levels.

(c) Since there were no detects of hexavalent chromium, chromium III cleanup levels were used as cleanup levels for total chromium.

(d) Background value from WAC 173-340-900, Table 740-1, footnote b.

Notes:

Phase IIa samples are shown in italics. Phase IIb samples are not italicized.

Framed cell indicates exceedance of protection of groundwater cleanup level.

Shaded cell indicates exceedance of direct contact cleanup level.

Detected metals concentrations less than background levels are not considered exceedances of cleanup levels.

REPORT: Geophysical Investigation  
Port of Everett Site, Everett, Washington

Dear Mr. Halbert:

This letter report summarizes the results of the geophysical investigation that I performed on December 22<sup>nd</sup> at the subject site. The primary purpose of the investigation was to determine if an underground storage tank (UST) was associated with a visible vent pipe adjacent to one of the buildings on the site. In another area of the site, scanning of the first boring location (Boring H3GW) was performed so that the boring would avoid hitting the two fuel lines in the area. However, detecting and tracing the fuel lines across the entire site was not straightforward with the geophysics. You decided that it would be more cost-effective to hand-auger the first few feet of the other borings in the area to avoid damaging a fuel line instead of using the geophysics.

A detailed ground penetrating radar (GPR) survey was made over the entire area of interest near the visible vent pipe. Scanning with a utility locator and a hand-held magnetometer was also performed to assist in identifying the possible pipes and utilities, and to confirm that no large amounts of shallow buried metal (such as USTs) were still present. A brief description of the methods is attached.

#### INTERPRETATION RESULTS

The Survey Results Map (Figure 1) shows the locations of the reference baselines and visible features at the site including the buildings, electrical conduit, vent pipes, etc. The vent pipe (2 inch diameter) had been cut previously a few inches above the pavement, and a rubber hose ran from the vent pipe into the building to the west. The pipe was cut to investigate further. The rubber hose contained wood chips, small dirt and debris, which were all covered in a black oily material.

Possible linear features interpreted from the data are probably utilities, but may also indicate other linear features such as foundations or former trench locations (discussed below). The vent pipe extends to the east (at a depth of about 1 foot) and is interpreted to terminate about 9 feet from the building. A possible linear feature runs north-south near east end of the vent pipe at a depth of about 7 feet. This north-south linear feature may indicate the bottom of the former UST excavation. It is a relatively faint signal, and not typical of a large metal object such as a UST. It also seems too deep to indicate the top of a UST – especially with the shallow groundwater conditions at this site. It may be an abandoned pipe or similar debris in the bottom of the former excavation. The soils near this north-south linear are also interpreted to be disturbed, which is another indication of a possible former UST excavation.

## METHODOLOGY

The GPR survey was performed using a Geophysical Survey Systems, Inc. SIR-8 GPR unit with both a 500 MHz antenna and a 200 MHz antenna, with data recorded on a thermal graphic recorder. GPR transects using the 500 MHz antenna were oriented both north-south and east-west and spaced 4 feet apart over the entire site. Additional lines were run near the vent pipe. Additional data were recorded in the area between the two buildings using the 200 MHz antenna. The 200 MHz antenna provides better depth penetration, but has less resolution of subsurface features.

Scanning of the area was also made using a utility locator and a hand-held magnetometer. These instruments provide an audible tone over a buried pipe or large metal object, which are then marked on the pavement.

The GPR survey was referenced to numerous reference baselines that were marked at 4-foot intervals using tape measures, a survey wheel, and white spray paint. The grid was established with coordinate 0E, 48N located at the northeast corner of the building to the east. Line 48E runs along the east side of the building. The locations of the possible buried vent pipe, and the north-south linear feature at 7 feet deep (possible former trench) were marked with blue spray.

Two example GPR profiles of the 500 MHz and 200 MHz data (Lines 8E and 10E, respectively) are provided on Figure 2. Horizontal distance is noted along the tops of the profiles, and depths along the side. The depths were estimated based on a two-way radar travel time of 5 ns/foot. This was determined using the signal characteristics of one of the GPR targets, and is typical of travel times in the Puget Sound area. The GPR depth of investigation at this site is about 12 feet.

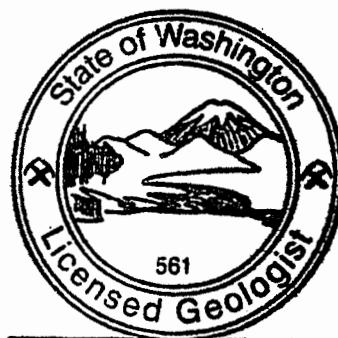

The use of GPR, utility locating and magnetometer scanning provided a rapid and non-intrusive means of investigating the area of interest for former USTs. However, because of the numerous variables involved in geophysical investigations, there is a possibility that some subsurface features may not have been detected, including possible USTs. Only direct observations using test pits or other means can ultimately characterize the anomalies and other subsurface conditions.

Please contact me if you have any questions or comments regarding this information, or if you require further assistance. I appreciated the opportunity to work with you on this project and look forward to providing you with geophysical services in the future.

Sincerely,

Philip H. Duoos  
Geophysical Consultant

## **DESCRIPTION OF METHODS**

### **GROUND PENETRATING RADAR**

Some of the uses of GPR include locating buried tanks and drums, delineating boundaries of landfills and trenches, and defining voids and geologic stratigraphy. Although other techniques can also provide this information, GPR is less affected by cultural interferences such as overhead powerlines, buildings, and fences. GPR can also provide higher resolution of the target in many cases. A variety of antennas can be used depending on subsurface conditions and the objective of the survey. Resolution of shallow objects requires higher frequencies, while lower frequencies work better for deeper investigations.

The profile recorder supplies the power and synchronizing signals to the antenna. The antenna outputs a pulse of electromagnetic energy to the ground. The energy pulse is reflected by geologic layers or objects under the surface back to the antenna. The antenna converts the pulse (nanoseconds in duration) to an analog signal (tens of milliseconds in duration) back to the radar unit. The signal is then processed and sent to a graphic recorder which creates a continuous profile of the subsurface reflectors.

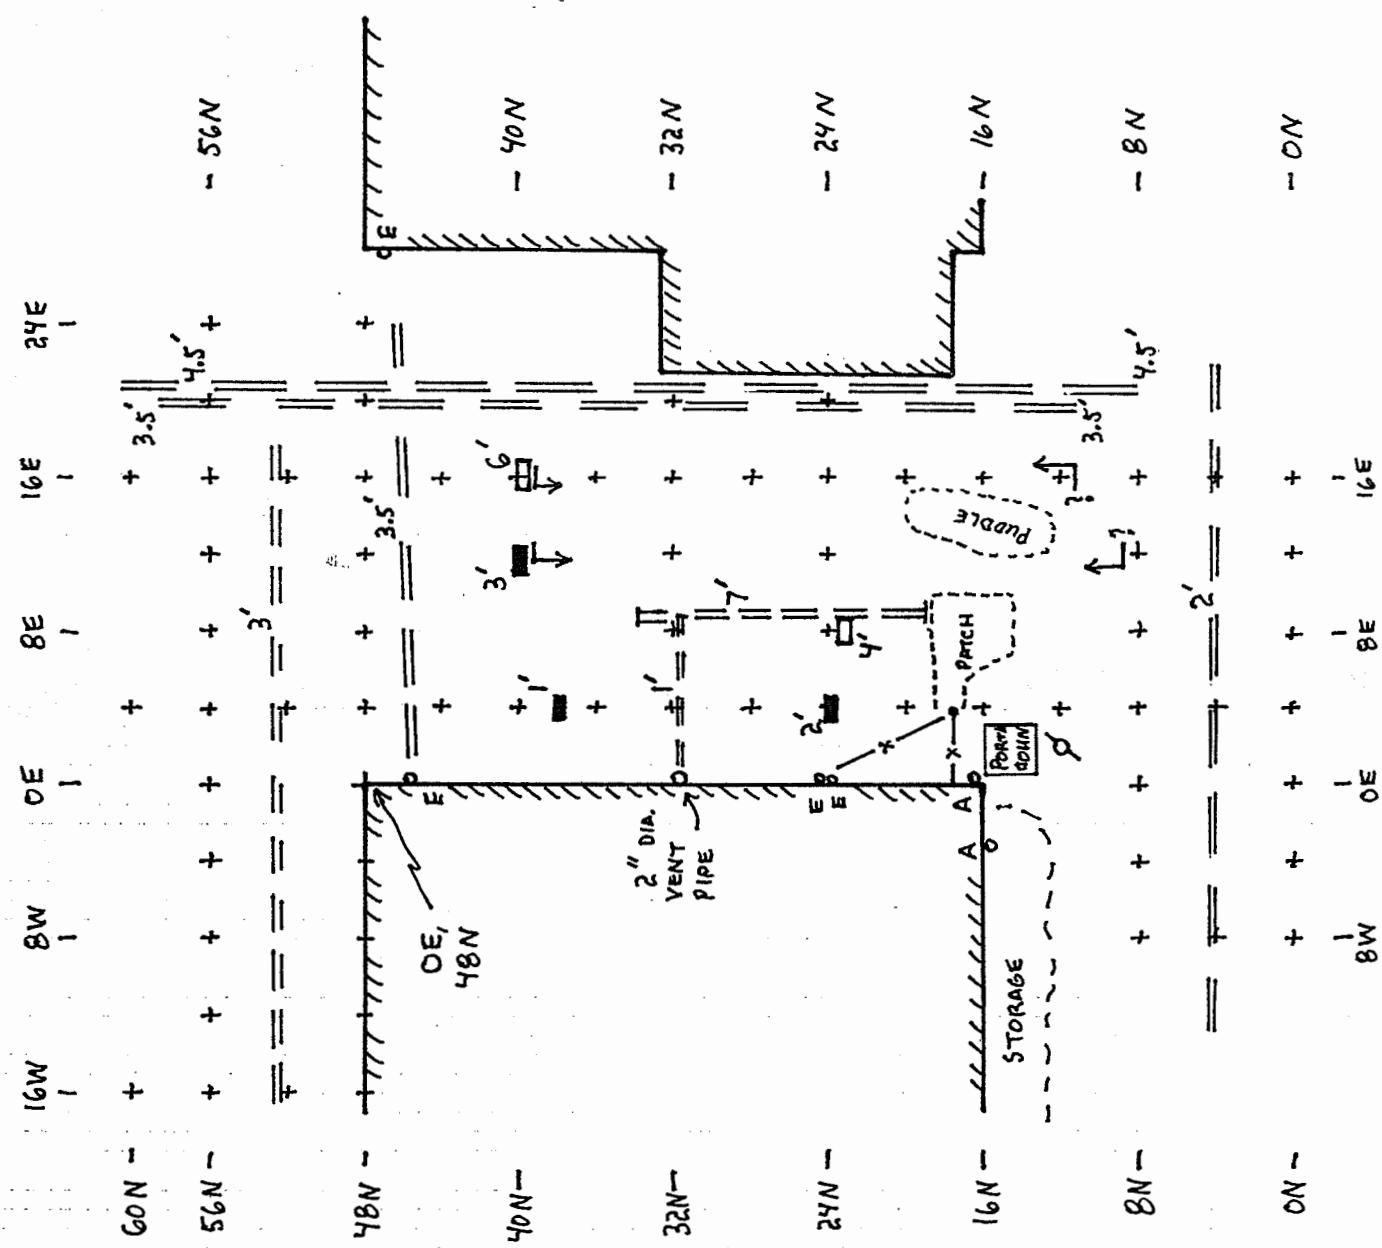

Several factors can affect the effectiveness of the GPR method including reinforced concrete at the surface, the presence of highly conductive materials (such as clays and water), the size, depth, and physical property of the target and; in stratigraphic investigations, the conductivity contrast between stratigraphic units. The presence of numerous buried objects may mask objects and/or stratigraphy below them.

### **RADIODETECTION UTILITY LOCATING**

The Radiodetection RD400 is an electromagnetic instrument that is used to locate utilities (such as metal pipes, electrical conduit, and communication lines). A handheld receiver unit detects the presence of electromagnetic fields in the pipes. These fields may be caused by the 50/60 Hz energy in active powerlines, or can be induced by VLF radio frequency energy passing through the earth. Most metal utilities can be located using the VLF field that is induced by a world-wide system of communication transmitters. In cases where a valve, vent pipe, or other portion of the utility is accessible, a small transmitter can be used to enhance detectability. This portable transmitter can be connected directly onto or located near the pipe.

### **MAGNETOMETRY**

The Schoenstadt magnetometer is a rapid, effective and non-destructive instrument used to locate buried ferrous material (drums, pipes, mineral deposits, archaeological objects, etc.). The instrument is operated and carried by one person, and uses an audible signal to indicate the presence of ferrous metal. Several factors can limit the effectiveness of the magnetometry method including the proximity of cultural interferences (such as buildings, fences and reinforced concrete), and the size, depth and magnetic susceptibility of the target

		GRAVEL WITH FINES <small>(Appreciable amount of fines)</small>	GC	Clayey gravel; gravel/sand/clay mixture(s)
	SAND AND SANDY SOIL <small>(More than 50% of coarse fraction passed through No. 4 sieve)</small>	CLEAN SAND <small>(Little or no fines)</small>	SW	Well-graded sand; gravelly sand; little or no fines
		SAND WITH FINES <small>(Appreciable amount of fines)</small>	SP	Poorly graded sand; gravelly sand; little or no fines
		SAND WITH FINES <small>(Appreciable amount of fines)</small>	SM	Silty sand; sand/silt mixture(s)
		SAND WITH FINES <small>(Appreciable amount of fines)</small>	SC	Clayey sand; sand/clay mixture(s)
FINE-GRAINED SOIL <small>(More than 50% of material is smaller than No. 200 sieve size)</small>	SILT AND CLAY <small>(Liquid limit less than 50)</small>	SILT AND CLAY <small>(Liquid limit less than 50)</small>	ML	Inorganic silt and very fine sand; rock flour; silty or clayey fine sand or clayey silt with slight plasticity
		SILT AND CLAY <small>(Liquid limit less than 50)</small>	CL	Inorganic clay of low to medium plasticity; gravelly clay; sandy clay; silty clay; lean clay
		SILT AND CLAY <small>(Liquid limit greater than 50)</small>	OL	Organic silt; organic, silty clay of low plasticity
	SILT AND CLAY <small>(Liquid limit greater than 50)</small>	SILT AND CLAY <small>(Liquid limit greater than 50)</small>	MH	Inorganic silt; micaceous or diatomaceous fine sand
		SILT AND CLAY <small>(Liquid limit greater than 50)</small>	CH	Inorganic clay of high plasticity; fat clay
		SILT AND CLAY <small>(Liquid limit greater than 50)</small>	OH	Organic clay of medium to high plasticity; organic silt
	HIGHLY ORGANIC SOIL	HIGHLY ORGANIC SOIL	PT	Peat; humus; swamp soil with high organic content

OTHER MATERIALS	USCS GRAPHIC SYMBOL	LETTER SYMBOL	TYPICAL DESCRIPTIONS
PAVEMENT	PAVEMENT	AC or PC	Asphalt concrete pavement or Portland cement pavement
ROCK	ROCK	RK	Rock (See Rock Classification)
WOOD	WOOD	WD	Wood, lumber, wood chips
DEBRIS	DEBRIS	DB	Construction debris, garbage

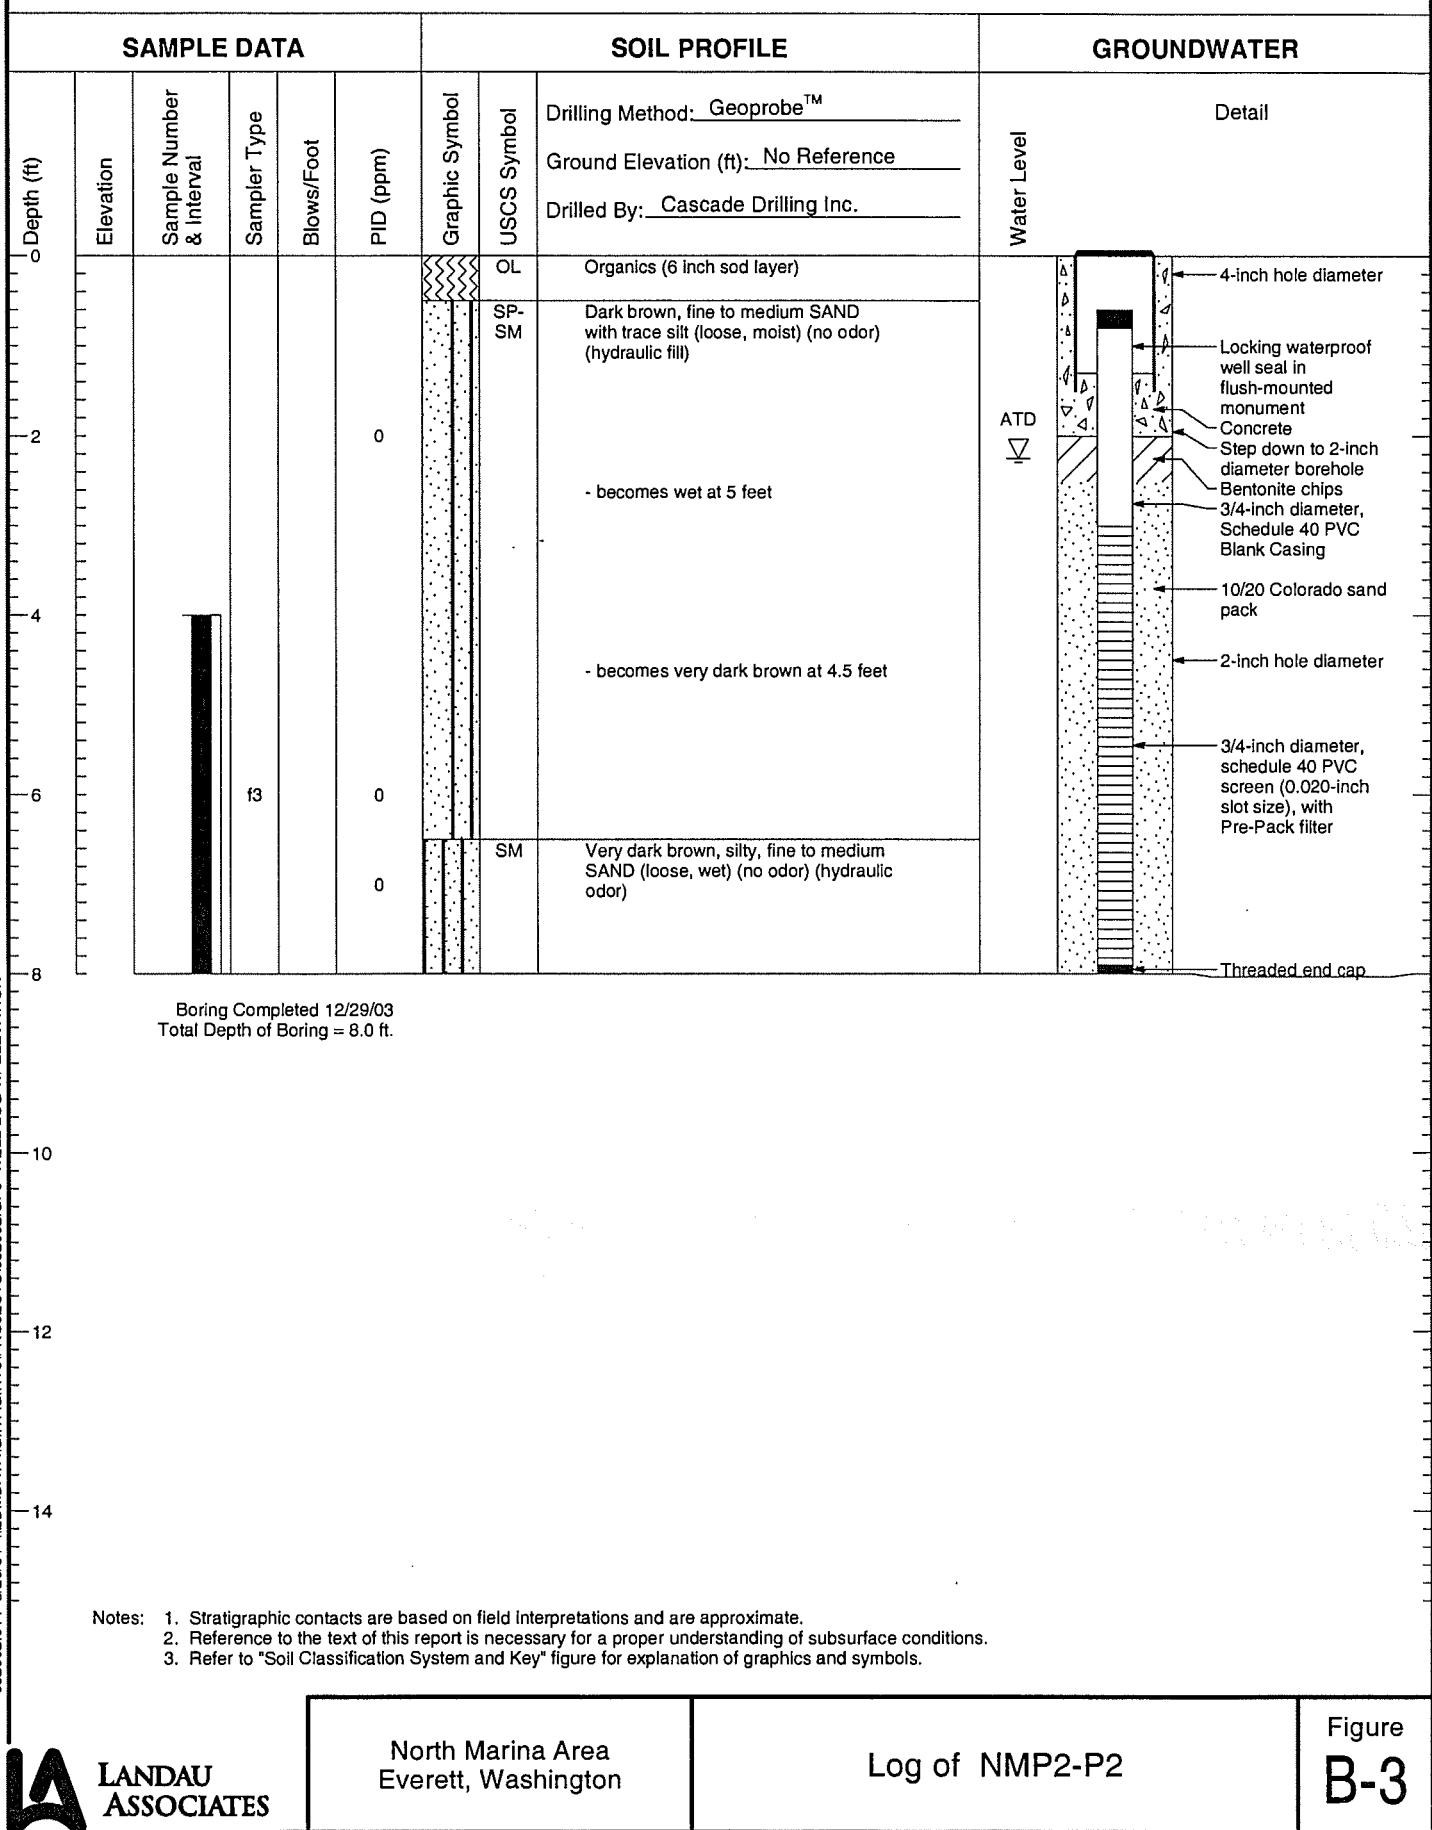

- Notes: 1. USCS letter symbols correspond to the symbols used by the Unified Soil Classification System and ASTM classification methods. Dual letter symbols (e.g., SP-SM) for a sand or gravel indicate a soil with an estimated 5-15% fines. Multiple letter symbols (e.g., ML/CL) indicate borderline or multiple soil classifications.
2. Soil descriptions are based on the general approach presented in the *Standard Practice for Description and Identification of Soils (Visual-Manual Procedure)*, as outlined in ASTM D 2488. Where laboratory index testing has been conducted, soil classifications are based on the *Standard Test Method for Classification of Soils for Engineering Purposes*, as outlined in ASTM D 2487.
3. Soil description terminology is based on visual estimates (in the absence of laboratory test data) of the percentages of each soil type and is defined as follows:
- Primary Constituent: > 50% - "GRAVEL," "SAND," "SILT," "CLAY," etc.
  - Secondary Constituents: > 30% and ≤ 50% - "very gravelly," "very sandy," "very silty," etc.  
> 15% and ≤ 30% - "gravelly," "sandy," "silty," etc.
  - Additional Constituents: > 5% and ≤ 15% - "with gravel," "with sand," "with silt," etc.  
≤ 5% - "trace gravel," "trace sand," "trace silt," etc., or not noted.

Drilling and Sampling Key		Field and Lab Test Data	
SAMPLE NUMBER & INTERVAL	SAMPLER TYPE	Code	Description
Sample Identification Number	a	3.25-inch O.D., 2.42-inch I.D. Split Spoon	PP = 1.0 Pocket Penetrometer, tsf
Recovery Depth Interval	b	2.00-inch O.D., 1.50-inch I.D. Split Spoon	TV = 0.5 Tovane, tsf
Sample Depth Interval	c	Shelby Tube	PID = 100 Photoionization Detector VOC screening, ppm
Portion of Sample Retained for Archive or Analysis	d	Grab Sample	W = 10 Moisture Content, %
1	e	Other - See text if applicable	D = 120 Dry Density, pcf
	1	300-lb Hammer, 30-inch Drop	-200 = 60 Material smaller than No. 200 sieve, %
	2	140-lb Hammer, 30-inch Drop	GS Grain Size - See separate figure for data
	3	Pushed	AL Atterberg Limits - See separate figure for data
	4	Other - See text if applicable	GT Other Geotechnical Testing
Groundwater		CA	CA Chemical Analysis
ATD	Approximate water elevation at time of drilling (ATD) or on date noted. Groundwater levels can fluctuate due to precipitation, seasonal conditions, and other factors.

cPAH TEQ		0.1 (b)		NA	NA	NA	NA	NA

NA = Not analyzed.

U = Indicates compound was analyzed for, but was not detected at the reported sample detection limit.

J = Result is an estimated value.

- (a) Background soil concentrations from Natural Background Soil Metals Concentrations in Washington State (Ecology 1994), unless otherwise noted.
- (b) MTCA Method A cleanup levels.
- (c) Since there were no detects of hexavalent chromium, chromium III cleanup levels were used as cleanup levels for total chromium.
- (d) Background value from WAC 173-340-900, Table 740-1, footnote b.

Notes:

Phase IIa samples are shown in italics. Phase IIb samples are not italicized.

Framed cell indicates exceedance of protection of groundwater cleanup level.

Shaded cell indicates exceedance of direct contact cleanup level.

Detected metals concentrations less than background levels are not considered exceedances of cleanup levels.

NA = Not analyzed.

U = Indicates compound was analyzed for, but was not detected at the reported sample detection limit.

M = Indicates an estimated value of analyte found and confirmed by analyst but with low spectral match.

J = Result is an estimated value.

(a) GW/MSW = Groundwater/Marine Surface Water.

(b) Groundwater background concentrations of Washington State (PTI 1989).

(c) MTCA Method A cleanup levels.

(d) Screening level is for chromium III.

(e) Background concentration from WAC 173-340, Table 720-1, footnote b.

Notes:

Phase IIa samples are shown in italics. Phase IIb samples are not italicized.

Shaded cell indicates exceedance of cleanup level.
