Abstract

Samples from four dischargers to the Spokane River and one waste contributor to a wastewater treatment plant (WWTP) were analyzed for polychlorinated biphenyls (PCBs) and associated general chemistry parameters during May 2001:

- Kaiser Aluminum at Trentwood (industrial)
- City of Spokane WWTP (municipal)
- Inland Empire Paper (industrial)
- Liberty Lake WWTP (municipal)
- Spokane Industrial Park wastewater to the Spokane WWTP (industrial to municipal)

A recently developed low-level method was used to analyze PCBs in all 209 possible congener forms in 159 groupings at practical quantitation limits, ranging from 76 pg/L to <1 pg/L. PCBs were also analyzed as Aroclor-equivalents in sludge samples from two of the facilities.

Samples from Spokane Industrial Park wastewater were found to have the highest concentrations of total PCBs (8,240 pg/L). Spokane Industrial Park contributes wastewater to the Spokane WWTP.

Of the four facilities discharging directly to the Spokane River, Kaiser Trentwood was found to have the highest total PCB concentration (7,670 pg/L). Inland Empire Paper, Spokane WWTP, and Liberty Lake WWTP samples were found to have total PCB concentrations of 2,440 pg/L, 1,790 pg/L, and 1,730 pg/L, respectively. These total concentrations are means of two grab samples collected on two consecutive days, with the exception of Inland Empire Paper for which a single grab sample was collected. Because total PCB concentrations were calculated by summing congeners, some of which were estimated values, they should be considered estimates.

Estimated loadings of total PCBs to the Spokane River during the survey were highest from Kaiser Trentwood and the Spokane WWTP (means of 0.48 g/day and 0.26 g/day, respectively). The estimated Kaiser loadings exceeded the combined loadings of all other sources monitored.

Total PCBs in the Kaiser effluent were lower in these survey samples than in samples collected in 1994 and 1995. Kaiser's efforts in recent years to clean up facility-related PCBs, and their use of a polymer flocculant during the survey sampling period, may have reduced PCB concentrations in the effluent.

Acknowledgements

The author would like to thank the following individuals for their help with this study:

- Katharine Kaye, Quality Assurance Chemist with AXYS Analytical Services Ltd., for discussing the AXYS method for estimating Aroclor-equivalent concentrations from congener data.
- These staff from the Ecology Manchester Environmental Laboratory:
 - Stuart Magoon for leading the way in researching state-of-the-art PCB congener analyses and the interpretation of results, and for acting as liaison with AXYS Analytical Services.
 - Karin Feddersen for investigating methods for estimating PCB Aroclor-equivalents, calculating estimated concentrations of PCB-1248, and performing data review of congener data.
- Ken Merrill, Ecology Water Quality Program, Eastern Regional Office, for providing guidance in developing the project and for reviewing the quality assurance project plan and study report.
- John Roland, Toxics Cleanup Program, Eastern Regional Office, for reviewing the study report.
- These staff with the Ecology Environmental Assessment Program:
 - Dale Norton, Toxics Studies Unit supervisor, for reviewing the quality assurance project plan and the study report and for providing guidance.
 - Art Johnson for reviewing the study report.
 - Carolyn Lee for assisting with sampling.
 - Gayla Lord and Joan LeTourneau for formatting and editing the final report.

Background

Polychlorinated biphenyls (PCBs) were once used in a variety of applications including insulating fluids, plasticizers, in inks and carbonless paper, and as heat transfer and hydraulic fluids. PCBs were first detected in the Spokane River in fish samples collected by the U.S. Environmental Protection Agency (EPA) and the Washington State Department of Ecology (Ecology) from 1978-1983 (Bailey and Singleton, 1984; Joy, 1984; Hopkins et al., 1985).

A study conducted in 1993 showed significant contamination of sediment and fish collected from five reaches of the Spokane River (Johnson et al., 1994). This prompted an investigation of PCBs in fish tissue, sediments, as well as industrial and municipal sources of PCBs to the Spokane River (Toxics Investigations Section, 1995). Further studies have included monitoring of PCBs from Spokane area point sources (Toxics Investigations Section, 1995; Golding, 1996; Golding, 2001).

PCBs can be analyzed as equivalent concentrations of commercial Aroclor mixtures or as individual PCB compounds called congeners. Aroclors are broad groupings of PCB mixtures designated by manufacturers before PCB production was banned by the EPA in 1979 (Toxics Investigations Section, 1995). In the past, Ecology has analyzed PCBs in wastewaters and other environmental samples as Aroclor-equivalents rather than as congeners. PCBs in the environment often appear as altered mixtures of Aroclors bearing little resemblance to the original products. PCBs in the environment that were originally various Aroclors weather and metabolize, making the identification and quantification of specific Aroclor mixtures in environmental samples uncertain in many cases.

Congeners are the 209 constituent chemical forms comprising PCBs. A numbering system has been adopted by the scientific community, with the 209 congeners ordered by number of chlorine atoms present and positioning of the chlorine atoms on the two benzene rings which form the structure of PCB compounds.

Previous analyses of whole wastewater effluent samples for PCBs as Aroclor-equivalents or congeners have been limited by the sensitivity of available analytical methods and equipment. A low-level analytical method published by the EPA in 1999 can now reliably quantify individual and grouped PCB congeners in whole-water samples. In addition, this congener analysis provides detailed information of the chemical constituents of PCBs in their basic congener forms. Of the 209 congener forms in PCBs, the analysis for this project reports all of these as 159 congeners/congener groupings.

With recently developed analytical techniques to identify a large suite of congeners at low levels, congener-specific methods are becoming preferred for PCB analyses where low quantitation limits are desired and/or where Aroclor-equivalent identification and quantification, a subjective process, would lead to uncertain results. Congener-specific analyses may have the potential for identifying signatures of PCBs from sources and in the environment. They also have the potential for accurately predicting sample toxicities (Sather et al., 2001).

Study Objectives

The objective of this survey, conducted on May 1 and 2, 2001, was to assess the presence and concentrations of PCBs in effluent sources discharging directly to the Spokane River. In addition, wastewater contributions from the Spokane Industrial Park to the Spokane WWTP were assessed for PCBs. Spokane Industrial Park operated a wastewater plant discharging to the river prior to 1994. Locations of the five sources sampled are shown in Figures 1-5.

The point sources monitored in this study were:

- Kaiser Aluminum at Trentwood (001 outfall) final effluent
- City of Spokane WWTP final effluent and sludge
- Inland Empire Paper final effluent
- Liberty Lake WWTP final effluent and sludge
- Spokane Industrial Park wastewater to the Spokane WWTP

Estimates are made of PCB loadings to the Spokane River at the time of the survey. Results from this study are compared with data from previous Ecology monitoring of point sources in the Spokane area. A discussion of estimating Aroclor-equivalents from congener analyses is included.

Sample Collection Methods

Sampling was conducted on May 1 and 2, 2001. Two whole-effluent/wastewater grab samples were collected at each facility, one on each of two consecutive days. The exception was Inland Empire Paper, for which a single grab sample was collected. Automatic compositing samplers were not used for this screening study because of the potential for contamination at the low levels of PCBs being analyzed. The large geographical area of the survey made collecting grab-composite samples impractical.

Effluent and wastewater samples were collected directly in pre-cleaned glass jars provided by AXYS Analytical Services. At Inland Empire Paper and Kaiser Trentwood, jars were held with powder-free nitrile gloves during sampling, with the jar openings facing upstream. At other locations, samples were collected by attaching the jars to poles and positioning the poles downstream of the sample jars. Lids were removed from the laboratory-cleaned glass sample jars just prior to sample collection and replaced immediately thereafter. A transfer blank was collected at Kaiser Trentwood by pouring deionized water supplied by AXYS into a sample bottle.

Sludge samples were obtained by collecting dried sludge directly into laboratory-cleaned wide-mouth jars. Sludge from the Spokane WWTP was collected as two samples from a belt filter press. Sludge from Liberty Lake WWTP was collected as one sample from a dried sludge drying bed and one sample from a partially-dried bed.

Total suspended solids (TSS), conductivity, and total organic carbon (TOC) were obtained by laboratory analyses of grab samples. Discharge flows were provided by facility personnel.

All samples were placed on ice in ice chests and maintained under chain-of-custody procedures.

Analytical Procedures and Methods

Effluent and wastewater samples were analyzed for low-level PCB congeners, rather than PCB Aroclor-equivalents as in previous Ecology monitoring efforts. The method used has been known to achieve low practical quantitation limits in receiving waters (Magoon, 2001). Sludge samples were analyzed as Arocolor-equivalents.

The Ecology Manchester Environmental Laboratory contracted congener analyses to AXYS Analytical Services Ltd. Manchester performed quality assurance and quality control verification of the data. Congener analyses were conducted in accordance with EPA method 1668A to achieve state-of-the-art resolution and detection limits. This high resolution gas chromatography mass spectrometry (GCMS) technique is an isotope dilution method, which provides internal standards for each congener. Labeled surrogates are added before samples are extracted, data from each sample are recovery corrected for losses in extraction and clean up, and analytes are quantified against similarly labeled analogues. PCB Aroclor-equivalent analyses based on EPA Method 8082A, by contrast, use an external standard with only limited spike samples and surrogates.

Sludge samples were extracted for Aroclor-equivalent analyses into acetone by Soxhelt extraction. The method is a modification of EPA SW-846 methods 3540, 3550, 3620, 3625, and 8082. The Aroclor-equivalent analyses were performed by Manchester Environmental Laboratory.

Data Quality Objectives

The practical quantitation limit (PQL) in an Aroclor-equivalent analysis is generally too high to quantify PCB concentrations in whole-effluent samples. In most instances, Aroclor-equivalent analyses can achieve a PQL only as low as 500 pg/L. Recently developed low-level analytical methods to determine PCB congener concentrations can provide expected PQLs as low as 20 pg/L. With this sensitivity, it was anticipated that PCB congeners in wastewater effluents could be evaluated at concentrations considerably lower than in previous Ecology sampling efforts.

AXYS Analytical Services Ltd. has achieved a method detection limit of 5-20 pg/L in freshwater. With the potential for matrix interference from the wastewater samples, 200 pg/L or lower was set as a target quantitation limit for the effluent/wastewater samples of this study (Magoon, 2001). This quantitation limit was considered low enough to quantify concentrations of PCBs.

For the Aroclor-equivalent analysis of sludge samples, a target PQL of 50 µg/Kg-dw (ppb dry weight) was set, based on previous experience (Magoon, 2001). In a 1994 Ecology study of solids from five wastewater-producing facilities in the Spokane area, all were found to have PCB-1248 in concentrations of 84 µg/Kg-dw or higher. Sludges from the Spokane and Liberty Lake WWTPs were found to have PCB-1248 concentrations of 220 µg/Kg-dw or higher (Golding, 1996). A quantitation limit of 50 µg/Kg-dw was considered to be sufficiently low for the analysis of sludge from these two facilities.

Quantitation Limits and Data Quality

The target PQL of 200 pg/L for the PCB congener analyses was met. Quantitation limits of 76 to <1 pg/L were achieved in the effluent/wastewater samples. Some congener group values were qualified as “NJs” because they exceeded quantification criteria for acceptable isotope ratios. Some values fell below the lowest concentration in the calibration series and, since linear interpolations could not be made, were below the lower method calibration limit (LMCL) and are qualified as “J” (Luszniak, 2002).

Twenty-six selected congeners in a sample of Spokane WWTP effluent (188185) were spiked to 100 pg/L. The absolute values of the deviations from 100% recovery had a mean of 1.6%. This is a small deviation relative to the control limits of 50% - !50% for Aroclor-equivalent EPA Method 8082.

The target quantitation limit of 50 µg/Kg for Aroclor-equivalents of sludge samples was not met as a result of matrix interferences. However, the limits achieved allowed for the quantitation of PCB-1248, -1254, and -1260 Aroclor-equivalents in most sludge samples.

Quality Assurance and Quality Control (QA/QC) Case Narratives are included in Appendix A.

Results

Results of the low-level congener analyses of final effluents from the four facilities discharging to the Spokane River, as well as wastewater from the Spokane Industrial Park (SIP), are summarized in Table 1. Total PCB congeners were calculated as the sum of all values, including those qualified as estimates. Non-detects were not included in total PCB congener calculations. Because some of the congener groupings included in the sums were estimated values, total PCB concentrations should be regarded as estimates. Complete congener data are shown in Appendix B. Daily average effluent flow for the discharges from the facilities was represented by flows measured for a 24-hour interval during the monitoring period, as reported by facility personnel.

* estimated values

** Kaiser Trentwood flow measured 7AM May 2 to 7AM May 3.

Spokane WWTP flow measured midnight May 1 to midnight May 2.

Inland Empire Paper flow measured 7AM May 1 to 7 AM May 2.

Liberty Lake WWTP flow measured 10 AM May 2 to 10 AM May 3.

PCB concentrations in the laboratory blank and field transfer blank (128 pg/L and 3 pg/L, respectively) were low relative to the effluent and wastewater samples. An upper limit for the transfer blank, 220 pg/L, was calculated by summing all measured and non-detected values as measured values. These low blank PCB concentrations indicate a lack of significant contamination in sample transfer and laboratory analyses.

Total PCB concentrations in effluents from the Spokane WWTP, Inland Empire Paper, and Liberty Lake WWTP were between 1,500 pg/L and 2,500 pg/L.

The two municipal WWTPs were discharging similar PCB concentrations, with a mean concentration ranging between 1,700 pg/L and 1,800 pg/L. The Spokane WWTP showed less variability than Liberty Lake, consistent with the averaging effect of higher contributing flows and greater detention times of a large city collection system and treatment facility. The single grab sample of Inland Empire Paper effluent had a PCB concentration of 2,440 pg/L, approximately 40% higher than those of the municipal WWTPs.

Spokane Industrial Park wastewater, though not discharging directly to the Spokane River, showed relatively high total PCB concentrations (7,110 pg/L, 9,370 pg/L).

Variability between pairs of sample results can be described in terms of relative percent difference (RPD). RPD is the difference between results as expressed as a percentage of the average. The RPDs for total PCBs in the Spokane and Liberty Lake effluents were 2% and 22%, respectively. Spokane Industrial Park, despite its relatively low wastewater flow and lack of equalizing treatment facilities, was found to have an RPD of 27%. These low RPDs suggest that a sample size of two per facility was adequate to characterize the effluents and wastewaters at the time of sampling at a level appropriate for a screening analysis.

The Kaiser Trentwood discharge showed high but variable total PCB concentrations, with 10,174 pg/L in one sample and approximately half that concentration, 5,165 pg/L, in the second sample. At the time these samples were being collected, Kaiser reported that the ferric system used to promote solids settling in the final lagoon had stopped working the week before sampling but that polymer was now being added to correct the problem (Blau, 2001). The RPD between the two Kaiser grab samples was 65%, considerably higher than those from the other facilities. This relatively high variability in PCB concentrations between the Kaiser effluent samples collected on consecutive days suggests non-steady state treatment conditions at the time of the survey.

Results of the effluent, wastewater, and transfer blank congener-group analyses are shown as histograms in Figure 6. In the histograms, each of the 209 congeners is represented by a plotted value. Because the laboratory method reported only 159 congeners or groupings of congeners, it was not possible to create histograms showing precise values of each congener. Since the distribution of congeners among a congener group is unknown, values were apportioned equally among the congeners in a group. For example, each congener of a group of four congeners with an overall value of 42.5 pg/L was plotted as 1/4 of that value (10.6 pg/L).

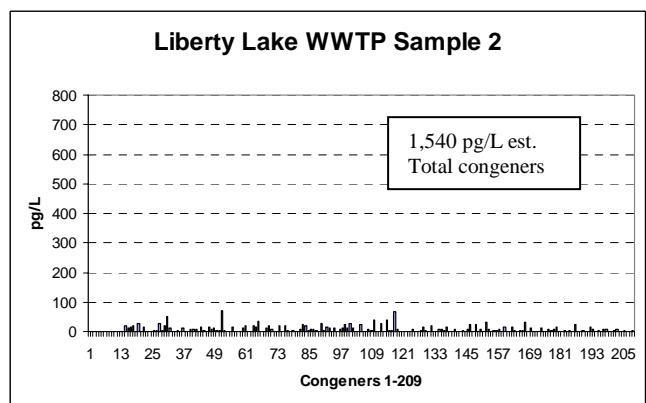

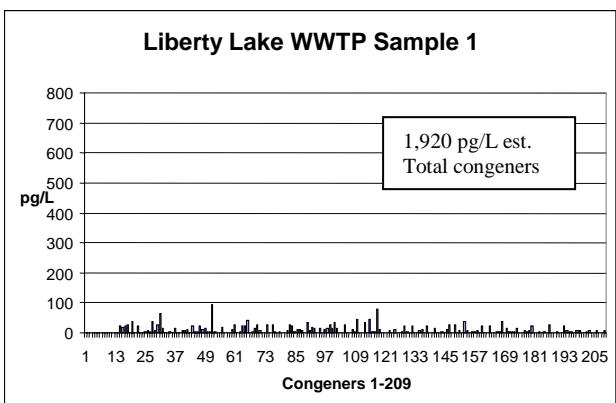

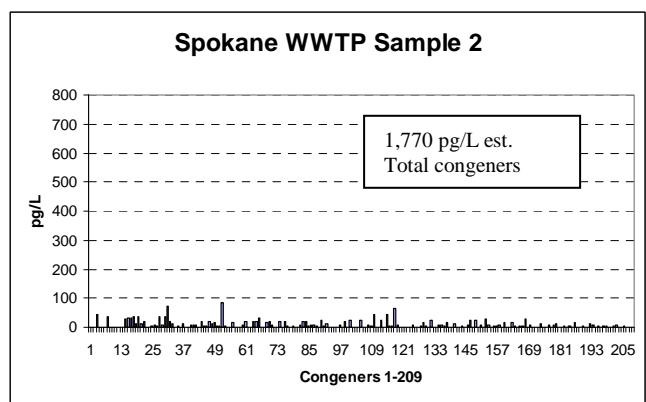

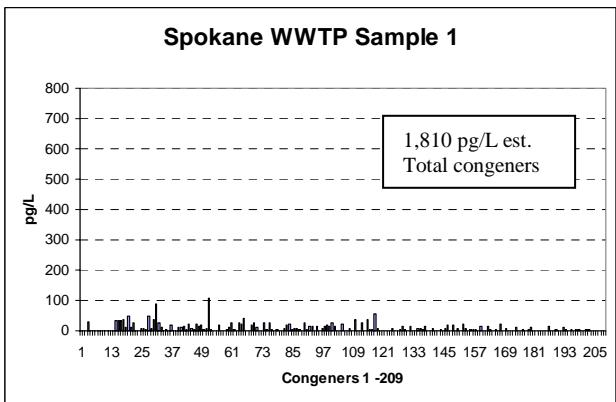

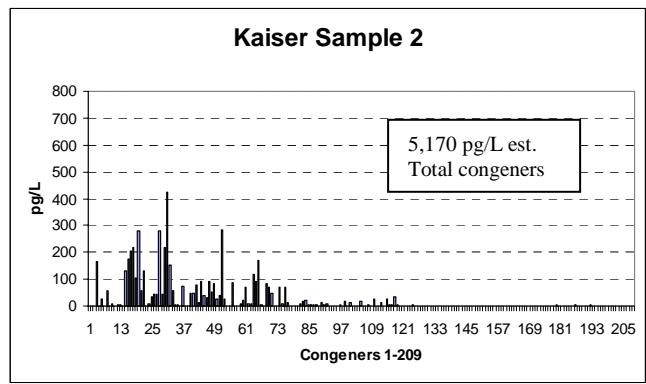

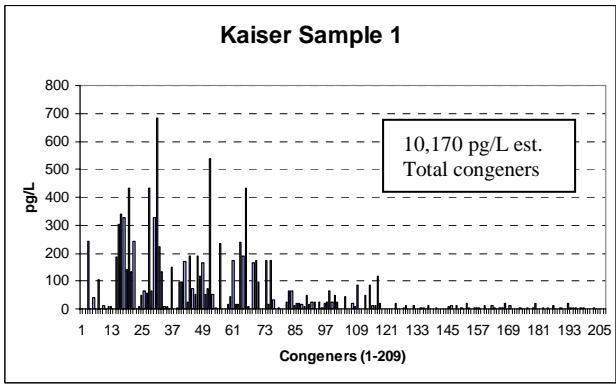

Figure 6. PCB Congener Distributions in Effluent and Wastewater Samples.

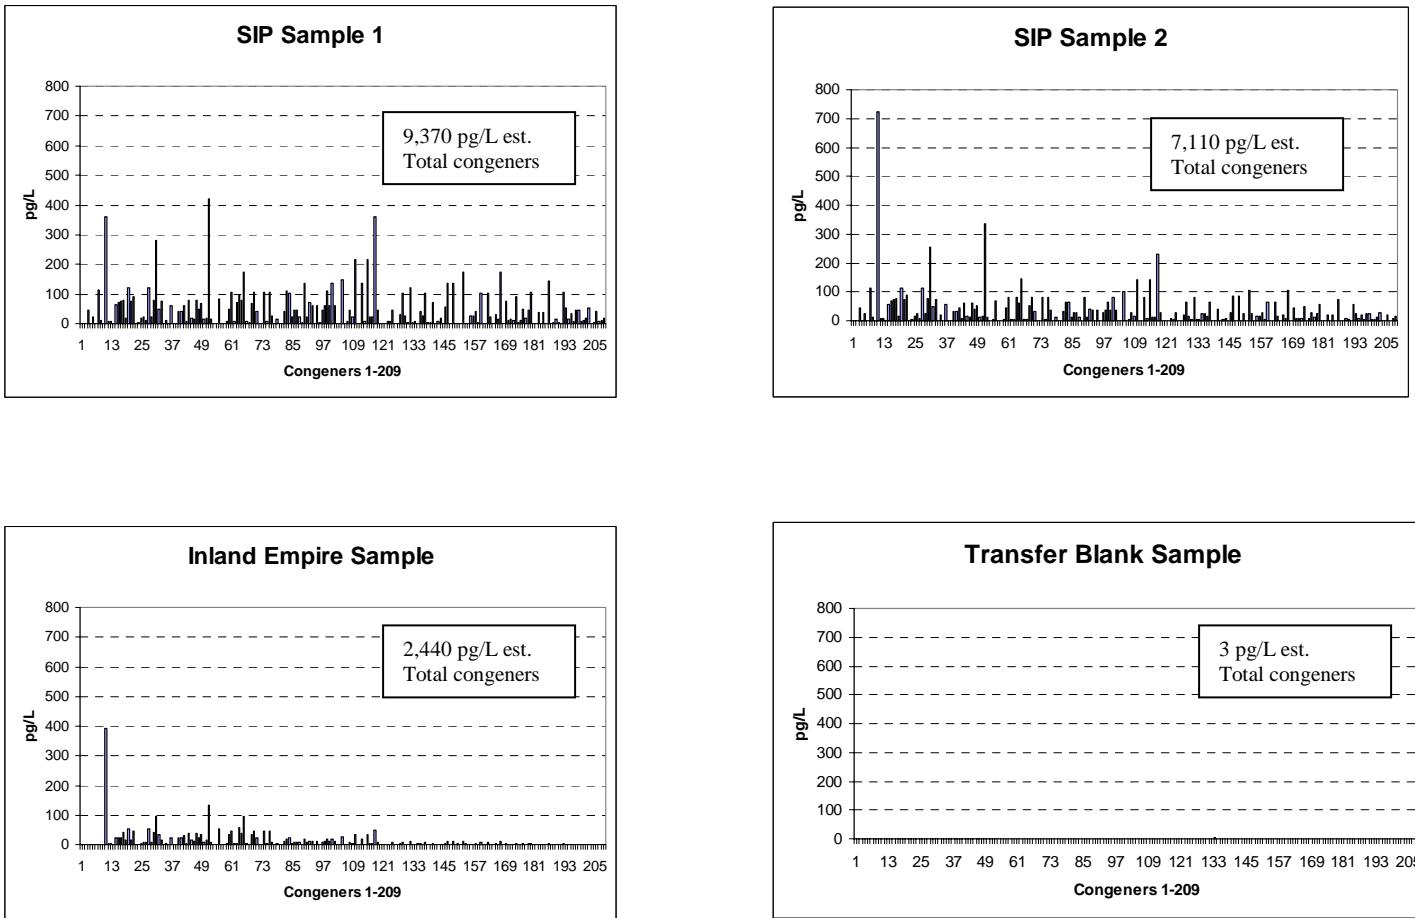

Figure 6 (cont.). PCB Congener Distributions in Effluent and Wastewater Samples.

The histograms show a similar pattern for Spokane and Liberty Lake WWTPs. Kaiser and Spokane Industrial Park (SIP) each have distinct patterns. Little difference is evident in the patterns from consecutive grab samples from each facility.

Results of the Aroclor analyses conducted on Spokane WWTP and Liberty Lake WWTP sludge samples are shown in Table 2.

Table 2. Sludge Data Summary.

TVS (%)	--	9.0	10.4	3.5	16.8
TOC (% carbon)	--	30.2	29.6	39.6	38.3

* Sludge samples from belt filter press

TVS – total volatile solids

** Sludge samples from sludge drying beds

TOC – total organic carbon

NJ - There is evidence the analyte is present. Associated numerical value is an estimate.

J - Analyte was positively identified. Associated numerical result is an estimate.

U- Analyte was not detected at or above the reported estimated result.

ND – non-detect

PCB-1248, -1254, and -1260 were found in sludges from both of these municipal WWTPs, with PCB-1254 being at the highest concentrations. Spokane sludge had higher total estimated PCB concentrations (195 µg/Kg-dw and 283 µg/Kg-dw) than Liberty Lake sludge (118 µg/Kg-dw).

Estimated PCB Loadings to the Spokane River

Total estimated PCB loadings to the Spokane River during the time of the survey appear in Table 3, calculated based on total PCB concentrations (total congeners) and point source flow rates (Table 1). Table 3 shows loadings from highest to lowest, with Kaiser Trentwood having the highest average loading (0.48 g/day).

Table 3. Estimated PCB Loadings to the Spokane River.

Source	Sample (2001)	Estimated Loading g/day	Average Loading g/day
Kaiser Trentwood 001	1 (May 1)	0.63	0.48
	2 (May 2)	0.32	
Spokane WWTP	1 (May 1)	0.26	0.26
	2 (May 2)	0.25	
Inland Empire Paper	(May 1)	0.040	0.040
Liberty Lake WWTP	1 (May 1)	0.0047	0.0042
	2 (May 2)	0.0038	

The estimated loading of total PCBs from Kaiser Trentwood on the day of its lowest loading (0.32 g/day on May 2) was higher than the estimated highest loading from all other sources combined (0.31 g/day on May 1). PCB loadings from Kaiser were estimated to be more than twice that of the next highest loading contributor, the Spokane WWTP, on the first day of monitoring (May 1) and 28% higher on the second day (May 2).

Loadings to the river from the Spokane Industrial Park (SIP) discharge to the Spokane WWTP could not be calculated, because the discharge is treated at the WWTP. SIP does not have a means of measuring wastewater flow. The flow appeared to be relatively low, in the sub-MGD range. In 1992 when SIP operated a WWTP, the flow averaged 0.6 MGD during an Ecology Class II Inspection (Hoyle-Dodson, 1993).

Estimating Aroclor-Equivalent Concentrations from Congener Data

In this screening study, PCBs were analyzed as congeners. The results are not directly comparable to the PCB Aroclor-equivalent results for wastewaters and associated solids in previous Ecology studies. A number of methods have been suggested to estimate Aroclor-equivalent concentrations from congener data (Newman et al., 1998; Frame et al., 1996).

Because there is considerable overlap in congener composition between Aroclor-equivalents (Sather et al., 2001), attempts to estimate Aroclor-equivalent concentrations from congener analyses tend to be less than successful when several Aroclors are suspected to be present (Feddersen, 2001; Kaye, 2002). Samples such as the effluents, wastewaters, and sludges of this study, and environmental samples in general, may have congener distributions that resemble more than one Aroclor. In addition, weathering and metabolic processes have altered the forms of PCBs found since Aroclor production was halted over 20 years ago (Sather et al., 2001).

Estimates of PCB Aroclor-equivalent concentrations from the congener data obtained in this survey are shown in Table 4. These estimates are based on a simplified method developed by AXYS Analytical Services Ltd. Using Aroclor standards of known concentrations, congeners unique to each Aroclor or most pronounced are summed and the result multiplied by a factor to yield the known Aroclor concentrations of the standards. The data and formulas used to develop these estimates appear in Appendix C.

As shown in Table 4, the total of the three Aroclor-equivalents for each sample, with the exception of Inland Empire, are higher than the total PCB congeners as summed from the 159 congener groups (Table 1) by an average of 21%. These estimates and Aroclor-equivalent data in general tend to overstate PCB concentrations, because Aroclor-equivalents share congeners and often overlap to some extent (Sather et al., 2001). With sufficient data, correlations between Aroclor-equivalent and congener-specific data have been made for selected tissue samples (Sather et al., 2001).

While AXYS provided estimates of Aroclor-equivalents from congener-specific data, the Aroclor-equivalent estimates are intended as a rough indication only, with totals approximating the more accurate totals obtained by summing congener group results (Phillips, 2002). When more than one Aroclor-equivalent appears to be evident but individual Aroclor-equivalents cannot be readily identified, AXYS routinely estimates PCB Aroclor-equivalents in terms of PCB-1242, -1254, and -1260. Aroclor 1248 is implicitly included in the estimates of PCB-1242 and -1254 in these rough estimates (Phillips, 2002).

Table 4. Aroclor-equivalent Estimates Based on Congener Proportions – AXYS Analytical Services Method.

Aroclor-equivalent	PCB-1242	PCB-1254	PCB-1260	Total PCBs from Aroclor-equiv Estimates

* AXYS does not quantify PCB-1248 when several Aroclor-equivalents are present.
 PCB-1248 estimates were calculated by Manchester Laboratory.

bold – detected analyte

NJ - There is evidence the analyte is present. Associated numerical result is an estimate.

UJ – Analyte was not detected at or above the reported estimated result.

J - Analyte was positively identified. Associated numerical result is an estimate.

As discussed in the following section of this report, PCB-1248 has been identified in historic Ecology Manchester Laboratory analyses of Kaiser Trentwood effluent and municipal WWTP sludges. For this reason, Manchester used the AXYS Aroclor-equivalent estimation technique to calculate values of PCB-1248, as shown in Appendix C (Feddersen, 2001). The estimated PCB-1248 values are as large as the Aroclor-equivalents estimated by AXYS. This, and the historic finding by Ecology of PCB-1248 and no other Aroclor-equivalents in the Kaiser effluent, support the view that the AXYS Aroclor-equivalent estimating method should not be regarded as indicating the presence of specific Aroclor-equivalents for the survey samples. Also, because PCB-1248 is included in the AXYS estimates of PCB-1242, -1254, and -1260, estimates of PCB-1248 cannot be compared with the other Aroclor-equivalents in Appendix C. (Phillips, 2002).

Comparison with Historic Data

Total PCBs, as determined in this study by summing congeners, are compared with historic data in Table 5, Figure 7, and Table 6. The historic data summarized in these tables have been published in previous Ecology reports (Toxics Investigations Section, 1995; Golding, 1996). PCBs from centrifuged solids from the Kaiser Trentwood outfall also have been analyzed by Ecology several times since 1990. Centrifuged solids results are not included in this report, because they are not comparable with whole effluent results.

Table 5. Summary of Historic Spokane Area PCB Point Source Data – Effluent and Wastewater Samples (pg/L).

Source	Lab#	Date	Method	Total PCBs*	Identified Aroclor
Kaiser Trentwood	188183	05/01/01	congener	10,174 NJ	NA

NJ - There is evidence that the analyte is present. Associated numerical result is an estimate.

U - Analyte not detected at or above the reported value.

NA – Not applicable

Total PCB Concentration (pg/L) Kaiser Trentwood 001 Outfall

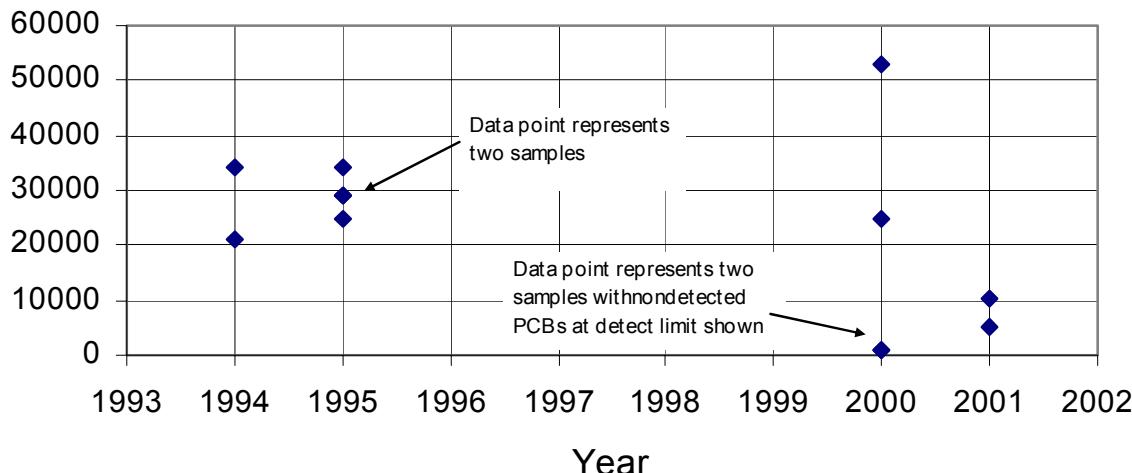

Figure 7. Kaiser Trentwood Outfall Total PCBs from Ecology Samples

The tendency for the congener constituents of Aroclors to overlap may cause the earlier data, which are based on Aroclor-equivalent sums rather than congener sums, to be overstated. Although comparable samples of PCB Aroclor-equivalent and congener analyses for wastewater samples are not available for this study, a comparison of Aroclor-equivalent versus congener data for 27 tissue samples in an unrelated study shows Aroclor-equivalent data overstating total PCBs by 8% (Sather et al., 2001).

While historic records of PCBs from Spokane area WWTP sludges extend back to 1994, as shown in Table 6, whole effluent analyses for PCBs have become sensitive enough to quantify PCBs for Spokane area sources other than Kaiser Trentwood and the Spokane Industrial Park only in the past few years. Kaiser Trentwood shows consistent and relatively high concentrations of PCBs during 1994 and 1995, with an average effluent PCB concentration of 28,000 pg/L (Figure 7). Kaiser subsequently made efforts to clean up operations and the wastewater treatment system. Ecology sampling during May of 2000 showed considerable deviation in results, ranging from 53,000 pg/L to nondetectable at 900 pg/L. Kaiser subsequently began applying coagulant to settle solids, upon which PCBs tend to sorb.

The results of the current 2001 monitoring, during which polymer was being applied, showed a reduction in PCBs discharged for the Kaiser Trentwood outfall from those of 1994 and 1995 (10,174 pg/L and 5,165 pg/L - Figure 7). Even so, as shown in Tables 1 and 3, results from Kaiser Trentwood effluent samples show the highest total concentration of PCBs and highest PCB loadings to the Spokane River during this May 2001 survey.

The relatively large variability in Kaiser Trentwood PCB data in 2000 and 2001 suggests that particular attention be given to sample size in designing future monitoring plans for the Kaiser outfall.

Table 6. Summary of Historic Spokane Area PCB Point Source Data – Sludge Samples, µg/Kg-dry .

Source	Lab#	Date	Method	Total PCBs	Identified Aroclor
Spokane WWTP	188189	5/2/01	Aroclor	195*	PCB-1248 PCB-1254 PCB-1260
Spokane WWTP	188192	5/2/01	Aroclor	283*	PCB-1248 PCB-1254 PCB-1260
Spokane WWTP	318169	8/2/94	Aroclor	510	PCB-1248
Liberty Lake WWTP	188193	5/2/01	Aroclor	118*	PCB-1248 PCB-1254
Liberty Lake WWTP	448080	11/01/95	Aroclor	300	PCB-1248
Liberty Lake WWTP	448081	11/01/95	Aroclor	220	PCB-1248
Liberty Lake WWTP	318174	8/3/94	Aroclor	4,400	PCB-1248
Spokane Industrial Park	318166	7/31/94	Aroclor	11,000	PCB-1248
Spokane Industrial Park	218088	5/25/94	Aroclor	12,000	PCB-1248

Bold - Analyte detected

* - estimated values

Total PCBs in one sample of Liberty Lake WWTP sludge collected in 1994 were high (4,400 µg/Kg-dry), but samples collected in 1995 and 2001 from the WWTP were an order of magnitude lower, slightly lower in concentration than sludge samples from the Spokane WWTP.

The 1994 sludge data for the Spokane Industrial Park were obtained from the Spokane Industrial Park WWTP, which had been recently closed.

Conclusions

The low-level congener analyses, as used in this study, have provided for the quantitation of PCBs in their constituent congener forms in effluent and wastewater grab samples. The low practical quantitation limits have allowed for the accurate quantification of PCB congeners and determination of total PCBs in all sources sampled. Although the sample size of two per facility was small, it appeared to be adequate to characterize the discharges at the time of the survey. The single grab sample from Inland Empire Paper, though insufficient to characterize an industrial discharge, identified a moderate concentration of PCB discharged relative to the other dischargers sampled.

Of the four facilities discharging directly to the Spokane River, Kaiser Trentwood was found to have the highest total PCB concentration. The mean of two grab samples of Kaiser Trentwood effluent taken on two consecutive days was 7,670 pg/L. The facility discharging the second highest concentration of total PCBs to the Spokane River was Inland Empire (2,440 pg/L). PCB concentrations and congener distributions were similar for the Spokane and Liberty Lake WWTPs. The Spokane Industrial Park, though not a direct discharger to the Spokane River, had the highest PCB concentration of any source sampled.

Calculated PCB loadings from Kaiser Trentwood exceeded the combined loadings of all other sources monitored (0.48 g/day avg.). Loadings from the Spokane WWTP were second (0.26 g/day avg.). The other two facilities discharging to the river had considerably lower estimated loadings.

Because of uncertainties in previous total PCB determinations based on Aroclor-equivalent analyses, comparisons with total PCB concentrations from the sums of congener groups performed in this current 2001 study should be viewed with caution. The reduction in total PCBs between the 1994 and 1995 Kaiser Trentwood effluent data, and data from this current survey during which polymer was used to settle solids, differ by more than a factor of 2 and are interpreted as real. However, the extent of difference between total PCBs as calculated from historic Aroclor-equivalent and current low-level congener analyses of effluent and wastewater is not known.

The use of low-level PCB congener analyses has proven to be an effective means of accurately quantifying PCBs in wastewater effluents. It is more meaningful to report PCBs as component congeners than as Aroclor-equivalents, since Aroclors are the original commercially-produced form of commercial mixtures of PCBs. In many cases, Aroclors have been altered in the environment. PCB analyses of wastewater sources – and potentially river water, sediments, and fish tissue – can provide a common basis by which to accurately quantify PCBs, assess toxicity, and potentially trace specific congeners from sources to their environmental fate.

Because Aroclor-equivalent analyses are considerably less expensive than low-level congener analyses, Aroclor-equivalent analyses may continue to be a useful means of determining PCB concentrations. The extent of Aroclor-equivalent mixing, weathering, the need for congener-specific data, and detection limits required are among the factors to consider in determining which method to use on a case-by-case basis (Bernhard and Petron, 2001).

Data Review for PCB Congeners

Summary

Data from these analyses were reviewed for qualitative and quantitative accuracy following the method 1668A.

Samples were prepared and analyzed according to EPA method 1668A.

Results have been reported in picograms per liter (pg/L), parts per quadrillion.

All results may be used as qualified.

Holding Times

EPA method 1668A allows storage of samples for one year from the date of collection. Extraction and analysis took place within this time frame.

Blanks

Low levels of certain target compounds were detected in the laboratory blanks. These congeners were also detected in the samples. If the concentration of a congener in a sample was less than five times that of the method blank, a "U" or "UJ" qualifier was added to the result. In cases where the sample concentration for a congener was greater than five times that of the blank, the blank result is considered insignificant relative to the native concentration detected in the sample. No qualification is warranted in these situations.

Calibration

The calibration standards were within 20% relative standard deviations (RSD) for all target analytes and 30% for all the labeled reference compounds (Internal Standards).

All calibration verification standard recoveries were within QC limits of 70% to 130% for target analytes and 50% to 150% for the labeled reference compounds.

All the ion abundance ratios and relative retention times were within QC criteria.

Internal Standard Recoveries

Internal standard recoveries for these samples were all within the method specified QC limits of 25% to 150% with several exceptions. As is discussed in the narrative from Axys, the ongoing precision and recovery standard (OPR) shows similarly low recoveries for some of the labeled compounds, yet all of the corresponding target analyte recoveries are well within the QC limits. Therefore, the analyte results in the samples are judged to be not affected and have not been qualified.

Ion abundance ratios

Each congener reported as detected met the isotopic abundance ratio and retention time criteria for positive identification with several exceptions. These exceptions have been qualified with "NJ".

On-going Precision and Recovery (OPR)

Target analyte recoveries were within quality control limits. Labeled compound recoveries were within quality control limits with the exceptions mentioned above (under Internal Standard Recoveries).

Data Qualifier Codes

- U - The analyte was not detected at or above the reported value.
- J - The analyte was positively identified. The associated numerical value is an estimate.
- UJ - The analyte was not detected at or above the reported estimated result.
- NJ - There is evidence that the analyte is present. The associated numerical result is an estimate.

AQUEOUS SAMPLES

EPA METHOD 1668A
PCB CONGENER, AROCLOR EQUIVALENTS

4078: L3455: 1 - 10
14 August 2001

Narrative:

Scope

This narrative describes the analysis of ten aqueous samples for PCB congeners and Aroclor equivalents determined using EPA Method 1668A.

Sample Receipt and Storage

Samples were received on 8th and 9th of May 2001. The samples were transferred to secure sample storage.

Analysis

The composition of the analysis batch is shown on the Sample Batch Summary form included with the data package.

PCB1668A: Representative sub-samples of each sample were taken and spiked with a suite of isotopically labeled surrogate standards, cleaned by column chromatography, and spiked with isotopically labeled recovery (internal) standards just prior to instrumental analysis. Analysis procedures were in general accordance with 'USEPA Method 1668, Revision A: Chlorinated Biphenyl Congeners in Water, Soil, Sediment and Tissue by HRGC/HRMS'.

Determination of PCB Aroclor Equivalents

Identification of PCB Aroclors in environmental samples is complicated by the similarities between the various Aroclor formulations and the compositional changes that can occur in the environment. Due to this, Axys Analytical Services Ltd. follows the convention that a single Aroclor is reported only when its unique Aroclor pattern can be identified; otherwise, Aroclors are quantified and reported as a mixture of the Aroclors 1242, 1254, & 1260.

The PCB Aroclor equivalent concentrations were determined from the summed concentrations of specific PCB congeners, characteristic of the Aroclor formulation, multiplied by an empirically determined quantification factor. The following PCB congener sets and empirical factors were used:

Aroclor	PCB congeners	Quantification factor
1242	8/18/31/28	3.8
1248	66/44/49	5.5
1254	87/97/99	10
1260	183/180/170	7.1

Instrumental analysis was conducted by high-resolution gas chromatography/high resolution mass spectrometry (HRGC/HRMS) on a VG magnetic sector high resolution MS equipped with an HP 6890 gas chromatograph, a CTC auto sampler, and an Alpha data system running Micromass software. An SPB-Octyl (30 m, 0.25 mm i.d., 0.25 µm film thickness) chromatography column was coupled directly to the MS source. The MS was operated at 10 000 (static) mass resolution in the electron impact ionization mode using multiple ion detection, acquiring at least two ions for each target and surrogate compound. Target concentrations were determined by isotope dilution or internal standard, with respect to the labeled surrogates added just after extraction, using Micromass OPUSQUAN software.

QA/QC

- Samples were analyzed following fully documented procedures in sample batches carried intact through the entire analytical process. The sample data was reviewed and evaluated in relation to the

batch QC samples. For results to be judged acceptable all data had to meet the quality acceptance specifications documented in the analytical method and on the data reporting forms.

- The acceptance range for percent recoveries of labeled PCB's 1 & 3 is not always attainable. All the target analyte concentrations are corrected by the surrogate recoveries as per the method. The OPR shows similar results for the labeled compounds and the associated target analytes are well within the method specifications. Axys feels that the data for the target analytes PCB's 1, 2 & 3 have not been significantly affected.
- OPR WG4439-102: percent recoveries of some labeled compounds were outside the method specifications; however, the percent recoveries of the associated target analytes were within the method specifications. Sample data have been accepted.

Analytical Discussion

- Those samples' analyte concentrations not exceeding 5 times the concentration observed in the associated LAB BLANK have been qualified with "UJ".
- Those samples' analytes not detected at the instrument detection limit calculated on an individual sample basis have been qualified with "U", and the detection limit has been entered into both of the concentration and detection limit fields.
- Those samples' analytes co-eluting with one or more other congeners (having a higher IUPAC number) have been qualified with "C". The concentration of the co-eluting group has been entered into the concentration field, and the instrument detection limit entered into the detection limit field.
- Those samples' analytes co-eluting with one or more other congeners (having a lower IUPAC number) have been qualified with "Cx", where "x" denotes the IUPAC number of the lowest numerical IUPAC designated congener in the group. There is no entry of a concentration or detection limit.
- Those samples' analytes having a concentration less than the lowest method calibration limit are qualified with "J".
- Those samples' analytes having been detected at the correct relative retention time but not meeting the ion abundance ratio specification are qualified with "NJ".

Reporting Conventions

Laboratory ID numbers of the form L3455-XX, (X are numerals), were assigned to the samples and used for internal identification. All data reports reference this unique Axys ID plus the client sample identifier.

Any extra work required and performed after the initial instrumental analysis of the extract is designated by a suffix to the sample identification, as follows:

R = repeat analysis from a backup portion of the sample

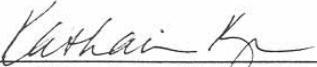

i = instrumental re-injection of the extract for reason stated on extraction log or batch summary

W = dilution and re-injection for the reason stated on the extraction log or batch summary

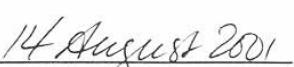

Data Package

Included in the data package are the raw, intermediate, and final data including laboratory worksheets, laboratory Batch Summary Sheets, sample and calibration chromatograms, instrument calibration summary data, instrumental run logs, OPUSQUAN calculation sheets, final data reports, chain of custody documents, hard copies of the GC temperature program used, mass resolution verifications, and a cross reference of Axys versus client identification numbers.

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. In addition, I certify, that to the best of my knowledge and belief, the data as reported are true and accurate. Release of the data contained in this data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature.

By: Myrna Mandjikov

PCB Aroclor Analysis of the Spokane Area Wastewater Sludge

Summary

Low percent solids and high concentrations of interfering compounds affected the reporting limits in this project.

The reporting limits differ between Aroclors because the lighter Aroclors 1016, 1221, 1232, and 1242 are not as sensitive as the heavier Aroclors 1248, 1254 and 1260. There is no evidence of the presence of lighter Aroclors in any sample.

If an Aroclor pattern was recognized below the laboratory reporting limit, it was reported and estimated. Results reported below the laboratory reporting limit but above the instrument detection limit are qualified as estimates, "J". If either the percent difference between the confirming columns or the standard deviation between the congener peaks chosen for quantitation are greater than 40 % then the result is qualified with "NJ.

There is evidence of Aroclors 1248, 1254 and 1260 present in sample 01188190 at an approximate level of 100 ug/Kg and Aroclor 1260 in sample 01188193 at about 20 ug/Kg. These values are not reported due to the high possibility of uncertainty in the identification and quantitation of the Aroclor peaks amidst the interfering compounds.

The data is useable as qualified.

Methods

The samples were extracted into acetone by Soxhlet extraction. Each extract was then eluted through a Florisil® column, with a 94% hexane / 6% preserved diethyl ether solution.

The extracts were solvent exchanged to iso-octane and treated with elemental mercury to remove sulfur and then treated with concentrated sulfuric acid. At this point each extract was analyzed by GC-ECD but the samples contained so much interference that no quantitation was possible.

100 uL of each sample extract was then eluted through a micro Florisil® column with 100% hexane, adjusted to 1 mL (10 fold dilution) and treated with concentrated sulfuric acid a second time prior to analysis by GC-ECD.

These methods are modifications of EPA SW- 846 methods 3540, 3550, 3620, 3665, and 8082.

Blanks

No target analytes were detected in the blanks.

Surrogates

All samples and blanks were spiked with decachlorobiphenyl (DCB) prior to extraction. All surrogate recoveries are within the acceptable range of 50 % - 150 % of the reference value.

Duplicate Samples

Sample 01188190 was prepared in duplicate. The level of Aroclors in the sample was too low to calculate the relative percent differences (RPD).

Spiked Sample And Duplicate Spiked Sample

Sample 01188192 was prepared in triplicate. Two replicates of the sample were spiked with Aroclors 1016 and 1260. All analytes recovered within the method control limits of 50 % - 150 %.

	LMX1	LMX2	RPD
Aroclor 1016	120 %	139 %	15 %
Aroclor 1260	122 %	137 %	12 %

Holding Times

The sample was extracted and analyzed within the recommended holding times.

DATA QUALIFIERS

Code Definition

- E Reported result is an estimate because it exceeds the calibration.
- J The analyte was positively identified. The associated numerical result is an estimate.
- N There is evidence the analyte is present in this sample.
- NJ There is evidence that the analyte is present. The associated numerical result is an estimate.
- NAF Not analyzed for.
- NC Not calculated.
- REJ The data are unusable for all purposes.
- U The analyte was not detected at or above the reported result.
- UJ The analyte was not detected at or above the reported estimated result.
- Bold Type** The analyte was present in the sample. Used as a visual aid to locate detected compounds on the report sheet.

June 4, 2001

TO: Steven Golding
FROM: Kamilee Ginder, Chemist
SUBJECT: General Chemistry Quality Assurance Memo for Spokane Area Wastewater PCB

Summary

The data generated by the analysis of these samples can be used without qualification. All analyses requested were evaluated by established regulatory quality assurance guidelines.

Sample Information

Samples for Spokane Area Wastewater PCB project were received by Manchester Environmental Laboratory on 05/04/01 in good condition.

Holding Times

All analyses were performed within established EPA holding times.

Analysis Performance

Instrument Calibration

Instrument calibration was checked by initial calibration verification standards and blanks. All initial and continuing calibration verification standards were within control limits. A correlation coefficient of 0.995 or greater was met. Balances are professionally calibrated yearly and calibrated in-house daily. Oven temperature is recorded before and after each analysis batch.

Procedural Blanks

The procedural blanks associated with these samples showed no significant analytical levels of analytes.

Spiked Sample Analysis

Spiked sample analyses were performed where applicable with all spike recoveries within acceptance limits of $\pm 25\%$. Spiked sample analysis is performed at a frequency of at least 5%.

Precision Data

Spiked sample results and duplicate sample results were used to evaluate precision on this sample set. Relative Percent Differences (RPD) for general chemistry parameters were within acceptance limits of $\pm 20\%$ for duplicate analysis. Laboratory duplication is performed at a frequency of at least 10%. Precision and accuracy specifications are based on sample concentrations greater than four times the reporting limit. For results near the reporting limit, the criteria are not guaranteed to be better than $+\text{-}$ the method detection limit.

Laboratory Control Sample (LCS) Analyses

LCS analyses were within the windows established for each parameter.

Other Quality Assurance Measures and Issues

The “U” qualification indicates that the analyte was not detected at or above the reporting limit.

Please call Jim Ross at (360) 871-8808 or Kamilee Ginder at (360) 871-8826 to further discuss this project.
