Abstract

The Washington State Department of Ecology (Ecology) collected monthly water quality data at 92 stream monitoring stations during Water Year 2011 (October 1, 2010 through September 30, 2011). We also collected 30-minute-interval temperature data at 27 sites, mostly from July through September 2011. In addition, we continued a continuous oxygen monitoring program at 13 sites.

The principal goals of this ongoing monitoring program are to monitor trends in water quality of rivers and streams in Washington State, to support a probabilistic monitoring program (Merritt, 2006), and to support Clean Water Act Section 303(d) reporting.

This report documents methods and data quality for Water Year 2011. This year's annual report includes a quality control (QC) analysis of continuously monitored data using multiple-parameter (oxygen, temperature, pH, and conductivity) instruments and a QC analysis of total phosphorus data collected from lakes monitoring for aquatic plants.

A description of Ecology's long-term monitoring program and access to historical data can be found on Ecology's web site at www.ecy.wa.gov/programs/eap/fw_riv/rv_main.html.

Acknowledgements

The success of the Water Year 2011 ambient monitoring program, and the quality of the data, are attributable to the following people:

- Several Department of Ecology staff spent long hours working in all kinds of weather, traffic, and road conditions. Without their dedication, Appendix D would be much longer. Water Year 2011 samplers (and their lifetime sample count) were Bill Ward (3524), Daniel Sherratt (1268), Jason Myers (709), Troy Warnick (480), Mike Anderson (216), and Dan Dugger (150).
- Bill Ward conducted the continuous stream temperature monitoring project.
- Jason Myers provided streamflow data.
- Brad Hopkins, Bill Ward, Mike Anderson, and Bill Kammin reviewed the draft report; Maggie Bell-McKinnon reviewed the lake monitoring sections; and Jenny Hall reviewed the multiple-parameter monitoring sections.
- Jenny Hall conducted much of the quality control review of the multiple-parameter monitoring.
- Joan LeTourneau formatted and edited the final report.

The following Manchester Environmental Laboratory staff did their usual meticulous best to provide high quality data with remarkably fast turn-around times. The folks there are a pleasure to work with.

- Nancy Rosenbower performed sample tracking services with help from Nancy Jensen, Aileen Richmond, Susan Carrell, Meredith Jones, and Deborah Clark.
- Dean Momohara supervised the Inorganics Section. Dean was always responsive to our needs and willing to re-analyze samples if there were any questions.
- Kim Archer, Daniel Baker, Crystal Bowlen, Sally Cull, Kamilee Ginder, Nancy Jensen, Aileen Richmond, and Rebecca Wood performed general chemistry analyses.
- Nancy Jensen, Sally Cull, and Susan Carrell were responsible for the microbiology.
- Sally Cull, Meredith Jones, Dean Momohara, and Rebecca Wood worked on low-level metals, and Sally Cull prepared metals sample containers.
- Leon Weiks provided sample containers and other supplies, and Leon and Dean provided transport services.
- Stuart Magoon managed the lab and kept everything working smoothly.

Introduction

The Washington State Department of Ecology (Ecology) and its predecessor agency have operated an ambient water quality monitoring program since 1959. Between 1995 and 2010, the basic program consisted of monthly water quality monitoring for conventional parameters at 62 long-term stations and 20 basin (rotating) stations on rivers and streams throughout Washington State. Beginning with Water Year (WY) 2011, we added more long-term stations and reduced the number of basin stations. In addition, we sampled 10 special project stations.

Our data are provided free to the public and are widely used by academics, consultants, local governments, schools, and others interested in the quality of Washington's flowing waters.

Within Ecology, data generated by ambient monitoring are used to:

- Determine if waters are meeting Washington State water quality standards or are in need of cleanup (e.g., www.ecy.wa.gov/programs/wq/303d/index.html).
- Identify trends in water quality characteristics (e.g., Hallock, 2005).
- Refine and verify Total Maximum Daily Load (TMDL) models.
- Develop water quality-based permit conditions.
- Conduct site-specific evaluations (e.g., Hallock, 2004).

A generalized assessment of water quality at particular stations is provided online (www.ecy.wa.gov/programs/eap/fw_riv/rv_main.html) in the form of a water quality index (WQI; Hallock, 2002). The WQI and trends at long-term stations are reported in *Washington State Water Quality Conditions in 2005 based on Data from the Freshwater Monitoring Unit* (Hallock, 2005).

Other Ecology programs conduct some of their own analyses. For example, Ecology's Water Quality Program applies its own data reduction procedures prior to producing Washington State's Water Quality Assessment [303(d) & 305(b) Report], which includes the list of waters needing to be cleaned up (www.ecy.wa.gov/programs/wq/303d/index.html).

This report describes the WY 2011 monitoring program and discusses the quality of the data collected in WY 2011. More detailed analyses and interpretations of ambient monitoring data are reported elsewhere (for example, see our reports at www.ecy.wa.gov/programs/eap/fw_riv/rv_main.html).

Goals and Objectives

The primary goals of the River and Stream Ambient Monitoring Program are to monitor trends in the water quality of Washington's rivers and streams, to support a companion probabilistic biological monitoring program (Merritt, 2006), and to support Clean Water Act Section 303(d) reporting.

Beginning with WY 2011, we modified the objectives for basin stations and added a new station type. See Hallock (2011) for a description of our previous monitoring design; a white paper discussing the redesign of our monitoring objectives is available on request.

- **Long-term station** objectives are unchanged. Stations are monitored every year to track water quality changes over time (trends), assess inter-annual variability, and collect current water quality information. These stations are generally located near the mouths of major rivers, below major population centers, where major streams enter the state, or upstream from most anthropogenic (human-caused) sources of water quality problems.

- **Basin stations** are selected to support the "Water Quality Assessment" process and federal Clean Water Act (303(d)) listings (http://ecy.wa.gov/programs/wq/303d/index.html). Specific objectives are to:
    - Confirm current Category 5 (*Polluted waters*) listings: Some listings are based on old or suspect data; recent data of known quality will help remove waterbodies from the Category 5 list that are currently supporting standards.
    - Determine a category for currently unlisted waterbodies.
    - Better define current Category 5 listings.
    - Resolve Category 2 (*Waters of concern*) listings: should they be Category 1 (*Meets standards*) or Category 5?
    - Identify "high quality" Tier III waters.

- **Sentinel sites:** These are "long-term" stations with the following objectives:
    - Support Ecology's probabilistic "Watershed Health" monitoring program.
    - Characterize reference conditions.
    - Provide trend data for reference conditions.
    - Monitor climate change.

- **Special project station** objectives are unchanged. These stations are typically sampled to address a particular question, and they are usually supported by funding external to the ambient monitoring program. We may not sample these stations for the entire usual suite of sampled parameters, or we may sample extra parameters. Special project stations will not necessarily represent typical water quality conditions.

Monitoring in Water Year 2011

In WY 2011, we monitored 66 long-term, 13 basin, and 3 sentinel stations (82 total). In addition, we monitored 10 stations associated with special projects (with external funding). Four of these were in Ecology's Northwest Region and six in the Southwest Region. All these stations were associated with the Intensively Monitored Watersheds (IMW) project (see www.ecy.wa.gov/programs/eap/imw).

Besides routine grab-sample monitoring, we conducted the following additional monitoring activities:

- 30-minute-interval temperature data collection from about July through September 2011 at several long-term and basin stations.
- Bi-monthly metals monitoring at 9 selected stations.
- Continuous monitoring for temperature, dissolved oxygen, pH, and conductivity at 13 stations, including six stations in support of IMW work. Results were delivered in near-real-time to the Internet by satellite telemetry at most stations.

Methods

Sampling Network

The ambient monitoring network in WY 2011 consisted of monthly water collection at all stations. We sampled all stations year-round.

Ambient stations monitored during WY 2011 are listed in Table 1. Appendix A lists current and historical monitoring locations and the years they were monitored by Ecology and its predecessor agency.

A description of our long-term monitoring program, access to most historical data, and previous annual reports can be found on Ecology's web site at www.ecy.wa.gov under the "Environmental Assessment" program and "River and Stream Water Quality."

Table 1. Ecology stream ambient monitoring stations for Water Year 2011.

Sample Collection and Analysis

We collected samples from the majority of stations as single, near-surface grab samples from highway bridges. We sampled a small subset of stations from the bank, off of culverts, and other locations. Sampling locations are identified on our web site.

We monitored for 12 standard water quality parameters monthly at all stations (Table 2).

Table 2. Water quality parameters monitored in Water Year 2011.
*Standard parameters collected at all stations are in **bold**.*

Parameter	Method	Typical Reporting Limit
Ammonia, total	SM 4500 NH3H	0.01 mg/L
Carbon, dissolved organic	SM 5310 B	1 mg/L
Carbon, total organic	SM 5310 B	1 mg/L
Chlorophyll	SM 10200H3	0.1 ug/L
Conductivity	SM 2510 B	NA
Fecal coliform bacteria	SM 9222 D	1 colony/100 mL
Hardness	SM 2340 B	Not specified
Metals: mercury	EPA 245.7	0.002 ug/L
Metals: other	EPA 200.8	various
Nitrate + nitrite, total	SM 4500 NO3I	0.01 mg/L
Nitrogen, total	SM 4500 NB	0.025 mg/L
Nitrogen, total (dissolved)	SM 4500 NB	0.025 mg/L
Oxygen, dissolved	SM 4500 OC	NA
pH	SM 4500 H+	NA
Phosphorus, soluble reactive	SM 4500 PG	0.003 mg/L
Phosphorus, total	SM 4500 PF	0.005 mg/L

Suspended sediment concentration	ASTMD3977B	1 mg/L
Temperature	SM 2550 B	NA
Turbidity	SM 2130	0.5 NTU

SM: APHA 2005.
EPA: U.S. Environmental Protection Agency, 1983.

Besides the 12 water quality parameters, we also recorded barometric pressure (to calculate percent oxygen saturation) and stream stage measurements, where necessary, to enable flow determination for most long-term stations and some basin stations. We collected metals samples bi-monthly (every other month) at 9 stations as well as additional parameters, such as total organic carbon and chlorophyll, by request at selected stations.

Sample collection and analytical methods are described in our standard operating procedures (Ward, 2007a; Ward, 2007b; Ward, 2011), ambient monitoring quality assurance (QA) documents (Hallock and Ehinger, 2003; Hallock, 2012; and Hopkins, 1996), and Manchester Environmental Laboratory's *Lab Users Manual* (MEL, 2008).

Program Changes

All long-term monitoring programs experience changes in sampling or analytical procedures that can potentially affect results. Normally, these changes are implemented to improve precision or reduce bias. Most changes will have only a minor effect on a synoptic analysis of the data, but even minor improvements in procedures should be considered when evaluating long-term trends.

We made no changes to collection, analytical, or quality control (QC) procedures in WY 2011 that we believe will affect trends.

However, we did find and correct some historical data errors, and we also prepared for an equipment change beginning in WY 2012:

- We had calculated instantaneous flow incorrectly at several stations from WY 2003 through WY 2009. These flows have been corrected in our database. We have decided to remove instantaneous flow data associated with our water quality data from our web pages and from EIM. Most flows are collected by agencies other than Ecology, using QC procedures we have not evaluated. The data we retrieve are often preliminary and subject to change. In addition, these data are already publicly available on the collecting agencies' web sites.
- We checked historical barometric pressures against station elevation and made a number of corrections. This analysis is discussed further in the *Quality Control* section of this report.
- The pH probe we have been using since 1991 (Orion liquid fill) is no longer being manufactured. We conducted several months of comparative tests in preparation for changing to a new pH probe and meter beginning in WY 2012. Results from these tests are reported in the *Quality Control* section of this report.

All known and suspected changes to methods and procedures during the history of the stream monitoring program, as well as large-scale environmental changes that may affect a trend analysis, are documented in Appendix B.

Continuous Temperature Monitoring

This program's goal is to collect summer, diel (24-hour) temperature data with 30-minute monitoring intervals at most long-term and current basin ambient monitoring stations, as well as at some special request stations. The data are primarily used for trend analyses and to determine the stream's compliance with water quality standards.

The scope of this program is being expanded (as resources and locations allow) with the establishment of year-round temperature (and seasonal oxygen) monitoring stations. Six long-term and two basin stations were installed during WY 2011 using a slant-pipe attached to the stream bank or to a shoreline structure.

We try to deploy the loggers that collect summer data by early July and retrieve them in late September. We also try to swap out the loggers at our year-round stations following a similar (June-September) schedule.

We deploy two Onset StowAway TidbiT® temperature loggers at each site, one in water and one in air. All deployed loggers are shaded with a PVC pipe and installed in a location considered representative of the surrounding environment. We usually install stream temperature loggers about six inches off the stream bottom to minimize potential influence from groundwater inflow. Loggers are placed in a free-flowing location at a depth to avoid exposure to air resulting from low streamflows.

Beginning in WY 2012, we intend to set all deployed loggers to *standard time*. Previously, we deployed loggers primarily during daylight savings time, and we used local time because it matched field sample times. However, year-round deployments cause problems with twice-yearly time shifts when using local time.

Detailed protocols are found in Ward (2011) and QC requirements in Ward (2005).

Continuous Multiple-Parameter Monitoring

Like temperature, oxygen concentration changes in a sinusoidal pattern over a 24-hour period. Oxygen concentration is typically lowest in the morning and highest in the late afternoon. Usually, daily lows are of the most interest because they have the most impact on aquatic life. Our grab-sample monitoring program does a poor job of capturing daily low oxygen concentrations.

To measure daily low oxygen concentrations, we need diel oxygen data. We are particularly interested in annual lows (usually occurring in mid to late summer), but also in daily low concentrations at the beginning and ending of salmonid spawning seasons, which vary according to location.

In WY 2011, we deployed Hydrolab® Minisondes with optical oxygen sensors (LDO) or In Situ® optical oxygen sensors (RDO) at 13 stations, 6 in support of the IMW project and 7 to supplement grab sample monitoring (Table 3). Most instruments were connected to near-real-time telemetry stations. We deployed self-contained systems (without telemetry) at three sites. All instruments recorded temperature, oxygen, and conductivity readings every 15 minutes. Several instruments also recorded pH. Our methods are described in Hallock (2009). We hope to expand this program in the future; however, we have no dedicated funding and are dependent on available resources.

Table 3. Stations monitored for continuous multiple-parameters in Water Year 2011.

Station	Name	Objective
08C110	Cedar R near Landsburg	Long-term; reference conditions
13A060	Deschutes R @ E St	WQS evaluation; support intensive monitoring project
19C060	West Twin R near mouth	Support IMW project
19D070	East Twin R near mouth	Support IMW project
19E060	Deep Cr near mouth	Support IMW project
23A070	Chehalis @ Porter	Oxygen is Category 2. Assess to move to Category 1 or 5.
25D050	Germany Cr @ mouth	Support IMW project
25E060	Abernathy Cr near mouth	Support IMW project
25F060	Mill Cr near mouth	Support IMW project
25G060	Coal Cr @ Harmony Rd	Initial assessment. Supplemental temperature criteria apply.
37J060	Snipes Cr near mouth	Oxygen and pH are Category 2. Assess to move to 1 or 5.
41A070	Crab Cr near Beverly	Oxygen is Category 2 (pH is 5). Assess to move to 1 or 5.
59C060	Sheep Cr @ Deer Cr Rd	Oxygen and pH are Category 2. Assess to move to 1 or 5.

WQS: Water Quality Standards. IMW: Intensively Monitored Watershed.

Metals Monitoring

Metals monitoring continued in WY 2011 at 9 stations (Table 4). Metals samples were collected every other month beginning in October 2010 at all stations except the Similkameen at Oroville. We monitored monthly in the Similkameen beginning in April to assess water quality prior to and during the re-opening of the Copper Mountain Mining Company's open pit copper mine in British Columbia, Canada.

Table 4. Bi-monthly sampling stations for metals in Water Year 2011.

Station	Name		Station	Name
10G080	Hylebos Cr @ 8th St E		49B070	Similkameen R @ Oroville
12C060	Flett Cr @ 75th St W		55B070	Little Spokane R nr mouth
25G060	Coal Cr @ Harmony Rd		56A070	Hangman Cr @ mouth
37J060	Snipes Cr nr mouth		57A150	Spokane R @ Stateline Br
39M100	Swauk Cr @ Lauderdale Junction			

Samples were analyzed for hardness and total mercury, as well as total and dissolved arsenic, cadmium, chromium, copper, lead, nickel, silver, and zinc. Collection and analytical methods are discussed in more detail in Ward (2007b) and Hopkins (1996).

Our current objectives for metals monitoring are as follows:

- Continue trend monitoring in the Spokane River at Stateline Bridge.
- Assess metals at the few remaining long-term stations where we have never collected metals data.
- Assess metals at basin stations in developed areas or in areas with a history of mining in the watershed.

Lake Monitoring

Although Ecology currently has no statewide lake monitoring program, Ecology management agreed to fund the analysis of total phosphorus samples collected from lakes visited by staff as part of Ecology's aquatic plant monitoring program. Plant monitoring staff collected 32 samples from 28 lakes (4 lakes were visited twice) in WY 2011.

The Quality Assurance Project Plan for this monitoring project is Bell-McKinnon (2011).

Quality Assurance

Ecology's Manchester Environmental Laboratory QA program includes the use of QC charts, check standards, in-house matrix spikes, laboratory blanks, and performance evaluation samples. For a more complete discussion of laboratory QA, see Manchester Laboratory's *Quality Assurance Manual* (MEL, 2006) and their *Lab Users Manual* (MEL, 2008).

The QA program for field sampling consisted of three parts:

1. Adherence to standard operating procedures (SOPs) for sample/data collection and periodic evaluation of sampling personnel.
2. Consistent instrument calibration methods and schedules.
3. The collection of field QC samples during each sampling run.

Our QA program is described in detail in Hallock and Ehinger (2003) and Hallock (2012).

Three types of field QC samples were collected:

1. *Duplicate (Sequential) Field Samples.* These consisted of an additional sample collection made approximately 15-20 minutes after the initial collection at a station. These samples represent the total variability due to short-term, instream dynamics; sample collection and processing; and laboratory analysis.
2. *Duplicate (Split) Field Samples.* These consisted of one sample (usually the duplicate sequential sample) split into two containers that are processed as individual samples. This eliminates instream and sample collection variability. Remaining variability is attributable to field processing and laboratory analysis.

3. *Field Blank Samples.* These consisted of the submission and analysis of de-ionized water. These are true field process blanks. The blank water was poured into cleaned sample collection equipment, and the sampler simulated collecting a water sample, including lowering the sampling device to the water surface. The expected value for each analysis is the reporting limit for that analysis. Significantly higher results would indicate that sample contamination had occurred during field processing or during laboratory analysis.

We submit QC samples semi-blind to the laboratory. Samples were identified as QC samples, but sample type (duplicate, split, or blank) and station were not identified.

In WY 2011, we processed 126 field QC samples for standard parameters: 13 field blanks, 57 field duplicates (sequential), and 56 field split samples. In addition, the laboratory conducted its own splits of some field QC samples. The central tendency of the variance of pairs of split field samples was summarized by calculating the square root of the mean of the sample-pair variances (root mean square; RMS). These figures provide an unbiased and higher estimate than other commonly used statistics (for example, mean or median of the standard deviations).

We use a two-tiered system to evaluate data quality of individual results based on field QC. The first tier consists of four automated checks: holding time, variability in field duplicates, reasonableness of the result, and the balance of nutrient species. Results exceeding pre-set limits are flagged. The second tier QC evaluation consists of a manual review of the data flagged in the first tier. Data are then coded from 1 through 9 (1 = data meet all QC requirements, 9 = data are unusable). Criteria for assigning codes are discussed in more detail in Hallock and Ehinger (2003). We do not routinely use or distribute data with quality codes greater than 4.

Finally, data management includes verification at several stages:

- We verify field data entry quarterly by comparing field data forms to printouts from the database.
- At the end of the WY, we electronically compare data in Ecology's EIM database, and in the database used for our web presentation, to the primary database.
- We visually check plots of streamflow versus stage height for anomalies. For flows determined independent of stage records, this method confirms the flow. (Most flows are derived from continuous recorders and based on date and time, not stage.) For flows based on stage, this method confirms that the flow was correctly determined from the flow curve, but the method cannot ensure that stage was correctly recorded.

Continuous Temperature Monitoring

The quality of the continuous temperature data was assessed by calibration checks using a certified reference thermometer before and after a deployment. If a pre-survey calibration check indicated that a logger's accuracy was not within the required limits (0.2 °C for water and 0.4 °C for air) when compared to a certified reference thermometer, then the logger was rejected and not deployed (Ward, 2005).

If a logger failed a post-survey calibration check, then the results may be rejected or, if the bias was relatively small and consistent (i.e., the pre-deployment bias was just within the required limits and in the same direction as the post-deployment bias), we may adjust results.

All datasets are graphically reviewed to identify and delete anomalies. In addition, we compare the data to the field temperature measurements taken at deployment and retrieval with a calibrated alcohol thermometer or thermistor. We also assess the differences between the continuous results recorded by the TidBit and monthly measurements collected during grab-sample monitoring surveys.

We upload all finalized results and summaries into our database, our webpage, and Ecology's EIM database.

Continuous Multiple-Parameter Monitoring

We used Hallock (2009) to assess the quality of data collected by multiple-parameter probes. In most cases, we compared grab sample results to continuous results determined by linear interpolation between the recorded results preceding and following the grab sample time. All times were first adjusted to Pacific Standard Time. We performed the following QC checks:

- Examination of a plot of continuous data overlaid with grab sample data for signs of outliers (caused, for example, by signal noise) in the continuous data, or drift in the continuous data compared to the grab data.
- Calculation of the mean difference between continuous and grab sample results. If >2%, continuous results were adjusted for offset and drift, where such adjustment was appropriate as indicated by a plot of the data. This adjustment was made prior to conducting additional QC evaluations.
- Comparison of the average relative standard deviation (RSD) of continuous and grab sample data pairs to the precision requirements in Hallock (2009).
- Comparison of individual differences between continuous and grab sample results to the accuracy requirements in Hallock (2009).

Results and Discussion

The primary purpose of this report is to present the results of Ecology's stream monitoring in WY 2011. The main body of the report describes the sampling program and interprets QC results. Appendix C describes where our monitoring data can be found. Raw data are available in computer formats on request and are posted on Ecology's web pages (www.ecy.wa.gov/programs/eap/fw_riv/rv_main.html). Unpublished data are also available online but are considered "preliminary."

Monthly Ambient Monitoring

A station-by-station data analysis is not within the scope of this report. Individual results not meeting the 2006 water quality criteria in Washington's Water Quality Standards (WAC Chapter 173-201A), excluding un-ionized ammonia, are identified in reports on our web site (www.ecy.wa.gov/apps/watersheds/riv/exceed). The un-ionized ammonia criteria are complicated to determine and are rarely exceeded (not met) in ambient waters. In WY 2011, no samples exceeded the chronic un-ionized ammonia criteria. Un-ionized ammonia was more than 10% of the chronic criterion at four stations: Mullen Slough at Frager Rd (09N050; on two occasions), Palouse River at Hooper (34A070), Colville River above Kettle Falls (59A080), and Skookum Creek near mouth (62B070).

Effective December 20, 2006, Ecology adopted an aquatic life system for classifying the state's waterbodies, dropping the AA, A, B, and C system in the 1997 standards (Ecology, 2006). Some of the numeric criteria from the new 2006 water quality standards are listed in Tables 5 and 6. The Ecology ambient monitoring program's comparison of results to water quality criteria on our web pages is not a formal determination of water quality *violations*. Determining violations requires additional considerations such as human impact or multiple results not meeting a criterion, and in some cases continuous data are desired.
(See www.ecy.wa.gov/programs/wq/303d//policy1-11Rev.html.)

Of the more than 13,000 possible standard water quality results in WY 2011, we missed collecting 401 results (3.0%). Most results (243) were missed because of weather-related causes such as the station being frozen or inaccessible due to snow. Other reasons for missing results included road construction or other access problems (60) and equipment failure (40). Appendix D gives more detailed explanations for each missed result.

Instantaneous flow data are still being gathered. Flow data from most of our stations are produced by the U.S. Geological Survey (USGS). USGS recently changed their data management procedures, which has affected the way we retrieve data from them. We hope eventually to obtain flow data for all 66 long-term stations and most of the 10 special project stations, though flows have been discontinued at some of these. Flows are not available for the 3 sentinel stations or for 10 of 13 basin stations (Table 7).

In addition, flows were not available at various times and stations due to ice, equipment failure, failure of the sampler to record stage, and unknown reasons. We identified all available flows from 17 stations as "estimated" because rating curves were out of date or imprecise, mean daily flow (rather than instantaneous) was used, or for other reasons.

Table 5. Water quality criteria in the 2006 water quality standards associated with aquatic life uses.[a]

Results outside the ranges shown do not meet the criterion.

Aquatic Life Use	Temperature (7-DADMax)[b] (°C)	Oxygen (1-day minimum) (mg/L)	pH (standard units)
Char spawning	<=9		
Char spawning and rearing	<=12	>9.5	6.5<=pH<=8.5
Salmon and trout spawning[c]	<=13		
Core summer salmonid habitat	<=16	>9.5	6.5<=pH<=8.5
Salmonid spawning rearing and migration	<=17.5	>8.0	6.5<=pH<=8.5
Salmonid rearing and migration only	<=17.5	>6.5	6.5<=pH<=8.5
Non-anadromous interior redband trout	<=18	>8.0	6.5<=pH<=8.5
Indigenous warm-water species	<=20	>6.5	6.5<=pH<=8.5

[a] WAC 173-201A-602 (Ecology, 2006) identifies use designations for waterbodies and some exceptions to the standard criteria listed above. Metals criteria, most of which are a function of hardness, are not listed here.

[b] 7-DADMax: 7-day average of the daily maximum temperature.

[c] An additional temperature criterion applies during specified seasons for some waterbodies (Payne, 2006).

Table 6. Water quality criteria in the 2006 water quality standards associated with contact recreation.[a]

Results outside the ranges given do not meet the criterion.

Recreation Use	Fecal Coliform Bacteria (cfu/100 mL)	
	10%	Geometric Mean
Extraordinary primary contact recreation	<=100	<=50
Primary contact recreation	<=200	<=100
Secondary contact recreation	<=400	<=200

[a] WAC 173-201A-602 (Ecology, 2006) identifies use designations for waterbodies.

Continuous Temperature Monitoring

During WY 2011, our monitoring goals were met at 19 western Washington and 5 eastern Washington stations (Table 8). We collected data from three additional stations that may not have included the critical period for temperature. We were unable to retrieve three eastern Washington water loggers: Methow nr Pateros, Methow @ Twisp, and Walla Walla River. Data from these stations may be available later.

The seven-day average of the daily maximum temperature (7-DADMax) failed to meet the basic 2006 criteria at most stations (19 of 27 stations, 70%). Four stations did not meet supplemental temperature criteria (Table 9). More stations would probably have failed the supplemental criteria, but deployment dates at most stations rarely include the beginning or ending of the supplemental season.

For the second year, seasonal maximum temperatures continued to be cooler than typical. In 2009, maximum temperatures at the warmest five stations ranged from 29.1 to 30.0 ºC. In 2011, maximum temperatures at the warmest five stations ranged from 22.7 to 26.8 ºC (Table 10). However, this is likely due, at least in part, to the relatively few stations monitored in WY 11, especially in eastern Washington.

Table 8. Temperature summary for Water Year 2011 (°C).

7-DADMax exceeding 2006 criteria (excluding special seasonal criteria) are shown in bold.

Station	Criterion	Sup. Criterion [a]	Deployment Maximum		7-DADMax [b]		Deploy Date	Retrieve Date

NS: Not sampled.

Continuous Multiple-Parameter Monitoring

Continuous data from multiple-parameter monitoring are maintained at the River and Stream Flow Monitoring web pages (www.ecy.wa.gov/programs/eap/flow/shu_main.html). We were unable to process data from stations supporting the IMW project (Table 3) in time to be included in this report. We rejected all results from stations 41A070-Crab Cr near Beverly and 59C060-Sheep Cr @ Deer Cr Rd (see the *Quality Control* section). Results from other continuous multiple-parameter monitoring stations are discussed below.

Oxygen

All 7-day averages of daily minimums (7-DADMin) of dissolved oxygen concentrations met or were better than criteria except at 25G060-Coal Cr, where the 7-DADMin was 9.2 mg/L, below the 9.5 mg/L criterion (Table 11). However, this concentration was very near full saturation. Limitations in oxygen concentration at this station are due to the effects of temperature on saturation. Coal Creek is not included in the 2008 Water Quality Assessment for oxygen (Koch, 2009).

Temperature

All 7-DADMax for temperature were warmer than the basic criteria except station 08C110-Cedar River near Landsburg (Table 11). Station 23A070-Chehalis River at Porter also exceeded the supplemental temperature criterion of 13ºC with a temperature of 19.0ºC on October 1, the beginning of the supplemental season. One or more reaches of the Deschutes River and Coal and Snipes Creeks are already listed as Category 5 for temperature in the 2008 Water Quality Assessment; the Chehalis River is Category 4A (Koch, 2009).

pH

Both station 23A070-Chehalis at Porter and station 37J060-Snipes Creek exceeded the upper pH criterion (Table 11). This reach of the Chehalis River is listed as Category 1 for pH and Snipes Creek is currently Category 2.

Table 11. Maximum 7-DADMax temperature and pH and minimum 7-DADMin oxygen compared to water quality criteria.

Values not meeting criteria are in bold.

Station	7-DADM[a]	Date[b]	Criteria/Comment
Dissolved Oxygen (mg/L)			
08C110	10.18	9/23/2011	7-DADMin ≥ 9.5 mg/L; data available between 8/13 and 9/30.
13A060	8.26	7/24/2011	7-DADMin ≥ 8.0 mg/L; data available between 6/30 and 7/27 and did not include the critical period. (Intermittent data available through 9/11. Minimum single-day DO was 7.68).
23A070	8.27	8/3/2011	7-DADMin ≥ 8.0 mg/L; data available between 7/13 and 8/9 and may not have included the critical period. (Intermittent data available through 10/1. Minimum single-day DO was 8.06).
25G060	**9.17**	8/24/2011	7-DADMin ≥ 9.5 mg/L; data available between 5/18 and 9/19.
37J060	8.07	8/2/2010	7-DADMin ≥ 8.0 mg/L; data available between 7/4 and 10/1. (Intermittent data available beginning 6/16.)
Temperature (ºC)			
08C110	12.7	9/24/2011	7-DADMax ≤ 16.0 °C and 13 °C; seasonal criterion 9/15 through 5/15; data available between 8/13 and 9/30. 7-DADMax after 9/15 was 10.5.
13A060	**18.1**	8/1/2011	7-DADMax ≤ 17.5 °C; data available between 6/30 and 9/12.
23A070	**21.7**	8/2/2011	7-DADMax ≤ 17.5 °C and 13 °C; seasonal criterion 10/1 through 5/15; data available between 7/13 and 10/1. Temperature was **15.7** on 10/1.
25G060	**19.0**	8/24/2011	7-DADMax ≤ 16.0 °C and 13 °C; seasonal criterion 2/15 through 6/15; data available between 5/18 and 10/1. 7-DADMax before 6/15 was 11.1.
37J060	**23.3**	8/2/2011	7-DADMax ≤ 17.5 °C; data available between 6/16 and 10/1.
pH (standard units)			
08C110	7.97	9/10/2011	6.5 ≤ pH ≤ 8.5; data available between 8/13 and 9/30. The individual daily maximum was 8.0.
13A060	NA		All pH data rejected
23A070	**8.6**	8/1/2011	6.5 ≤ pH ≤ 8.5; data available between 7/28 and 8/15. The individual daily maximum was **8.6**.
25G060	NA		All pH data considered "unreliable estimate."
37J060	**8.7**	7/17/2011	6.5 ≤ pH ≤ 8.5; data available between 6/16 and 10/1 with several intermittent periods of rejected data. The individual daily maximum was **9.3**.

[a] The highest 7-day average of daily maximums in each dataset for temperature or pH, or the lowest 7-day average of daily minimums for dissolved oxygen datasets.
[b] Date is the middle of the averaged 7-day period.
DO: Dissolved oxygen.

Metals Monitoring

During WY 2011, we collected all of the 918 possible metals results (9 stations x 6 samples x 17 analytes).

Of the 486 dissolved metals and total mercury results reported, 11 (2.3%) exceeded 2006 Washington State water quality standards chronic criteria (Table 12). Dissolved zinc did not meet (exceeded) the criterion in the Spokane River at Stateline in all months zinc was sampled, and dissolved lead exceeded criteria half the time. The Spokane River has a TMDL for metals (Butkus and Merrill, 1999), mostly due to legacy contamination from upstream mining practices. See Hallock (2010) for an analysis of long-term metals monitoring data from the Spokane River.

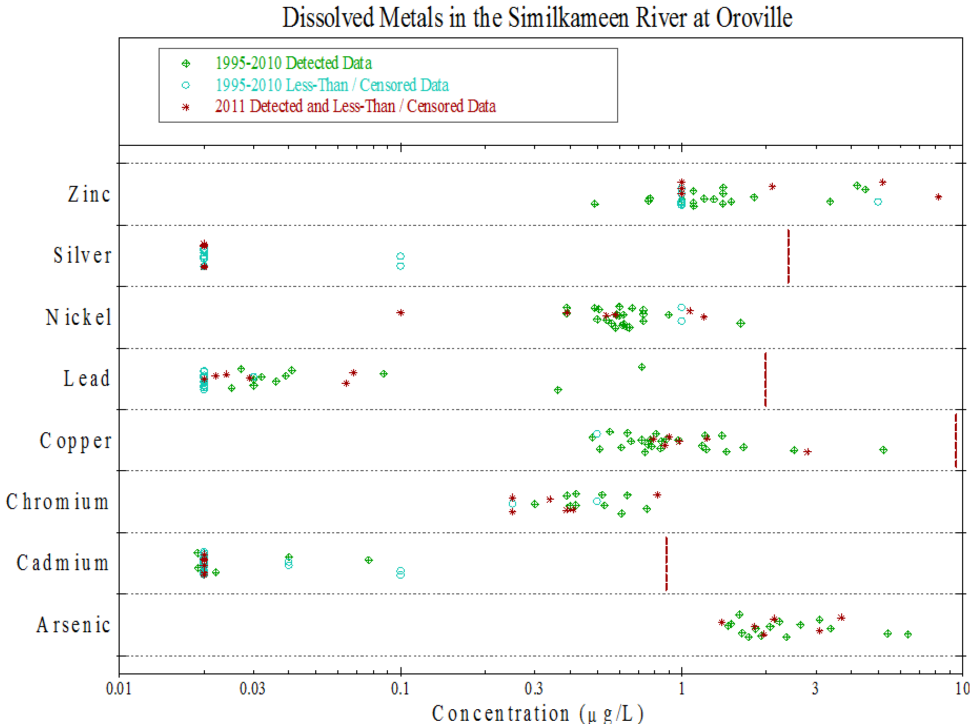
Mercury exceeded the chronic criterion a single time at three different sites but never by much. It is not unusual to see occasional isolated mercury results exceed the criterion.

Table 12. Metals results from Water Year 2011 exceeding 2006 water quality standards criteria.

Date	Parameter	Hardness (mg/L)	Result (ug/L)	Chronic Criterion (ug/L)	Percent Over Chronic Criterion	Acute Criterion (ug/L)	Percent Over Acute Criterion
Hylebos Cr @ 8th St E							
12/08/2010	Hg	NA	0.0176	0.012	47%	2.1	--
Swauk Cr @ Lauderdale Junction							
04/04/2011	Hg	NA	0.0192	0.012	60%	2.1	--
Similkameen R @ Oroville							
5/23/2011	Hg	NA	0.0152	0.012	27%	2.1	--
57A150 Spokane R @ Stateline Bridge							
10/12/2010	Zn_DIS	22.1	35.8	29.0839	23	31.85	12%
12/20/2010	Zn_DIS	23.8	48.8	30.9687	58	33.91	44%
2/23/2011	Pb_DIS	21.3	1.93	0.4516	327	11.59	--
2/23/2011	Zn_DIS	21.3	55.1	28.1893	95	30.87	78%
4/11/2011	Pb_DIS	19.6	2.34	0.411	469	10.55	--
4/11/2011	Zn_DIS	19.6	56.1	26.271	114	28.77	95%
6/21/2011	Pb_DIS	17.5	0.674	0.3615	86	9.28	--
6/21/2011	Zn_DIS	17.5	35.8	23.8657	50	26.14	37%

Hg: mercury.
Zn_DIS: dissolved zinc.
Pb_DIS: dissolved lead.

Metals concentrations in the Similkameen River at Oroville in 2011 were similar to concentrations reported previously (Figure 1). A two-sample t-test assuming unequal variances (an f-test rejected the hypothesis of equal variances) failed to reject the hypothesis that means from the two data sets were the same ($p<0.05$).



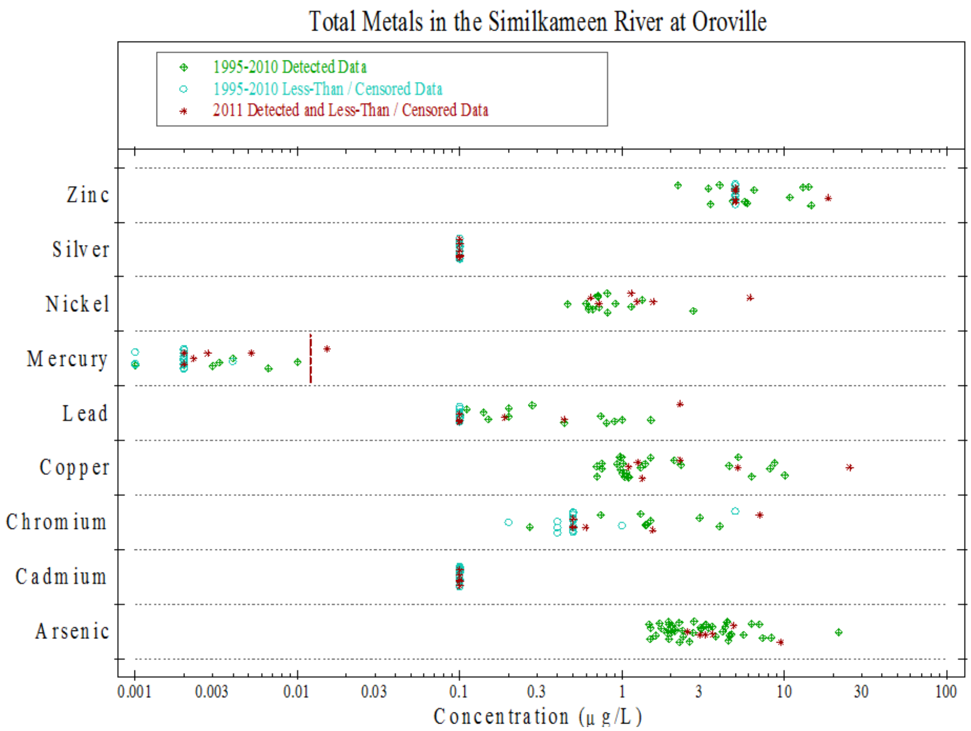


Figure 1. Dissolved (top) and total (bottom) metals in the Similkameen River at Oroville.

Vertical lines show the water quality criteria for dissolved metals and total mercury at the average hardness for the Similkameen. All criteria are chronic except for silver, which is acute. Water quality standards for arsenic (190 ug/L), chromium (149 ug/L), nickel (131 ug/L), and zinc (87 ug/L) are off scale.

Lake Monitoring

An analysis of total phosphorus data collected from lakes in 2011 is beyond the scope of this report. Data are available from Ecology's EIM database under project ID AMS002B-2 (provisional data) or AMS002B (published data).

Quality Assurance

In WY 2011 we collected almost 16,000 non-QC water quality results, including metals and various other parameters in addition to the standard 12 parameters listed in Table 2.

- We coded 55 results (0.3%) "4" indicating that the data are usable, but there were questions about the quality. These were from a variety of stations, dates, and parameters.
- We coded 356 results (2.2%) "5" or greater indicating serious data quality questions; these data will not be routinely used or provided. This practice gives us the opportunity to explain quality issues to prospective users before they obtain the data. About half of these were barometric pressure measurements from eastern Washington in January through August where the barometer had failed (see the following *Barometric Pressure* section). For these samples, elevation will be used instead of measured pressure to determine percent oxygen saturation. Many of the remaining results were from Eastern Washington in July through September that we coded "9" due to a possible mix-up in samples.

Manchester Laboratory assigned a qualifier to 16% of usable results. Of these, 547 results (3.5%) were qualified as estimates ("J"), 1948 results (12%) as below the reporting limit ("U"), and 5 results (0.03%) were coded as both estimates and below the reporting limit ("UJ"). A total of 68% of all ammonia results were below the reporting limit, as were 13% of orthophosphate results and 37% of all metals results (Table 13).

Table 13. Results qualified by Manchester Laboratory as being below the reporting limit.

Parameter	Reporting Limit (mg/L except where otherwise noted)	Number of results coded U or UJ	Number of unqualified results	Percent of results coded U or UJ
Ammonia	0.01	731	1072	68%
Chlorophyll	0.05 ug/L	0	33	0%
Fecal coliform bacteria	1	105	1072	10%
Hardness	Not specified	0	55	0%
Metals	Various	368	990	37%
Nitrate+Nitrite	0.01	92	1072	9%
Nitrogen, total	0.025	24	1072	2%
Organic carbon, dissolved	1	129	399	32%

Barometric Pressure

We use barometric pressure (BP) to calculate percent oxygen saturation. BP varies during the course of the day (the atmosphere has a tidal cycle), and weather systems can cause BP to vary by 38 mm Hg or more, which equates to a variation of about ±0.3 mg/L in the theoretical oxygen concentration at saturation or ±3% in the calculated percent saturation. (For more discussion of pressure and saturation, see Brown and Hallock, 2009.)

Unfortunately, analog barometers, especially, can be mis-read, off scale at higher elevations, improperly calibrated, and inaccurate, especially when cold. Elevation can be used as a surrogate for BP but with consequences for the precision of saturation calculations.

This report includes an evaluation of the difference between calculated BP based on elevation and reported BP (Figure 2). The data between the 1st and 99th percentiles are within the expected range of normal variability in BP at a location. The analysis indicated one station where elevation had been incorrectly recorded, one recent 8-month period where a barometer had failed (not shown in the plot, below), and a number of individual results that were suspect. Results outside the 1st and 99th percentiles were coded “4” (questionable), and results outside the 0.1st and 99.9th percentiles were coded “5” (probably bad). For data coded “5”, we recommend that elevation be used for percent saturation calculations.

We also implemented a database procedure to warn samplers during data entry if the difference between the calculated BP and their recorded BP is outside the 10th and 90th percentiles.

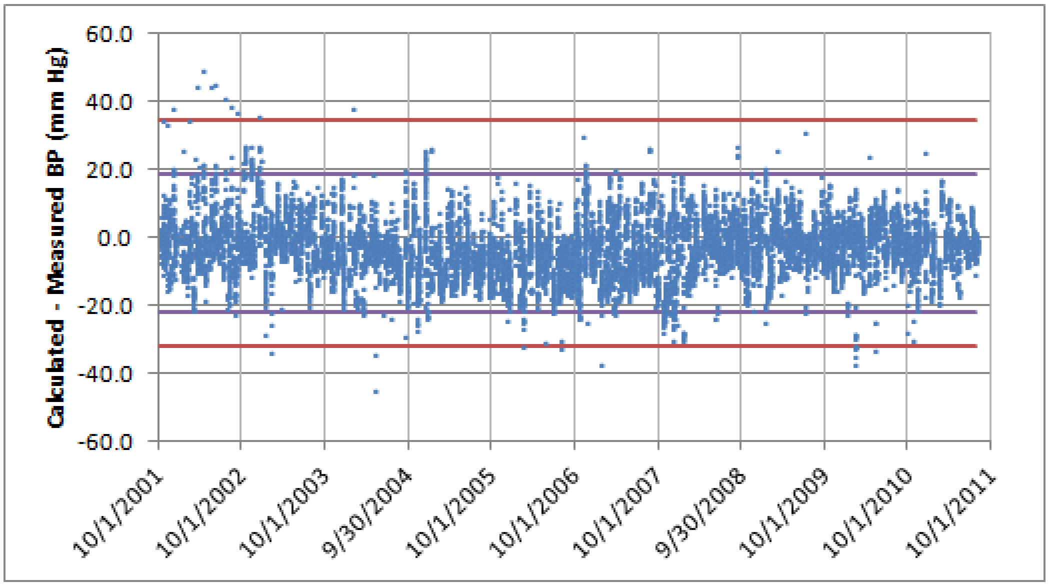

Figure 2. Difference between calculated barometric pressure (BP) based on elevation and measured BP for 10 years of ambient data.

Inner purple lines are the 1st and 99th percentiles; outer red lines are the 0.1st and 99.9th percentiles.

pH

We used our usual Orion pH and conductivity meters throughout WY 2011. However, because the probe we have been using for years is no longer being manufactured, we explored other options and eventually settled on the Hach HQ40d combination meter for both pH and conductivity. We will document procedures specific to this meter in an update to our SOP (Ward, 2007b).

We spent March through June testing the instrument with side-by-side comparisons and refining protocols. From July through September, all samplers collected pH data using both the Orion and the Hach pH meters following standard protocols. A total of 95% of results were within ±0.2 standard units, with little bias between the two meters (mean Orion minus Hach = -0.020, standard deviation = 0.101 standard units, N=276). These results are similar to informal tests of two Orion meters. In a test of three Hach meters analyzing 4 samples, the maximum difference was 0.16, and the average absolute difference was 0.075 (standard deviation=0.040 standard units).

Informal tests on conductivity indicated that results from Orion and Hach meters were highly comparable.

Errors in EIM and Web Databases

Data verification identified 53 instances where results in the EIM database ("transitional" project AMS001-2) were different than results in our primary database. All but one of these were from 4 stations with incorrect dates in EIM. One mis-matched result was a mis-entered pH value collected on 10/26/2011 from Coal Creek (25G060) which we had failed to correct in EIM. In addition, 3 oxygen results from 1/10/2011 had not been entered into EIM at all, and 169 results were present in EIM that had been coded as "bad" in the primary database. Most of these were barometric pressures collected from several stations between January and July where the instrument had failed. The rest were from the Spokane River at Stateline (57A150), which we removed due to a possible mix-up in samples. We corrected the EIM database in April 2012.

Eight results in our preliminary web database did not match results in our primary database, most likely due to a data entry error that we corrected in the primary database but not on the web. In addition, 5 results were missing in the web database. We corrected or loaded these 13 results in April 2012.

Comparison to Quality Control Requirements

Decision Quality Objectives

Decision quality objectives (DQOs) are based on RMS values by concentration range (Table 14). In practice, estimates of variability are strongly influenced by extreme values, especially when the sample size is small. Also, the variability estimate is skewed downward for the lowest concentration ranges because data below the reporting limit are censored and, therefore, sample pairs below this limit have a variance of zero.

In general, variability of repeated measures followed the expected pattern of field sequential samples > field split samples > lab split samples. However, in a number of cases, lab split samples had greater variability than field QC samples, probably because lab splits are often based on different samples than the field QC samples. Field sequential samples occasionally had less variability than the field splits. Usually, a single field split pair with poor precision was responsible.

Variability between paired samples as measured by RMS was generally low.

Two field split constituent/concentration ranges failed the Quality Assurance Monitoring Plan (QAMP) DQO (Hallock and Ehinger, 2003), which specifies that DQOs be evaluated against field splits, where possible. The mid-range of ammonia and total phosphorus samples exceeded DQOs due to one particularly poor sample split in each case (0.01U/0.051 and 0.033/0.069 mg/L, respectively).

Two field sequential constituent categories failed to meet the DQO criteria, but instream variability is included in these sample pairs so their variability is not a true measure of sampling plus analytical error. As in years past, the variability in sequential samples for total suspended solids (TSS) concentrations tends to be particularly high. This underscores the inherent variability in measurements of stream sediment.

One lab split constituent/concentration range failed DQO requirements. The highest range of turbidity samples exceeded the DQO due to one particularly poor sample split (30 and 110 NTUs).

Table 14. Root mean square (RMS) of the standard deviation of sequential samples, field splits, and laboratory splits.

Results not meeting (exceeding) QAMP DQO criteria (Hallock and Ehinger, 2003) are shown in bold.

Parameter (units)	Range	$S_{err\ (mp)}$ [a]	Field Sequential RMS	n	Field Split RMS	n	Lab Split RMS	n

[a] Maximum permissible standard error to meet Quality Assurance Monitoring Plan (QAMP) DQO (Hallock and Ehinger, 2003).

n: number of sample pairs.

NA: not applicable.

The criteria in Table 14 are based on desired trend power. (We want to be able to detect a 20% change over a ten-year period with 90% confidence.) Parameters that consistently do not meet the DQO criteria are unlikely to meet our goals for trend detection. The variability in most parameters indicates equivalent or greater trend power than the goal specified in our QAMP (Hallock and Ehinger, 2003). Our ability to detect trends in TSS, however, is likely to be worse than our goal.

Measurement Quality Objectives

Measurement quality objectives (MQOs) for accuracy are based on comparisons (usually against standards) during calibration checks (Hallock, 2012). Checks failing criteria cause an immediate corrective action (usually recalibration). Bias MQOs are evaluated at the laboratory based on spike recovery. Precision MQO evaluations are based on comparisons to average relative standard deviation (RSD) of field split pairs. Results are presented in Table 15.

Only the suspended sediment concentration (SSC) exceeded MQO criteria based on field split samples or sequential samples. However, we only collected three SSC sequential samples, and all were near the detection limit where even a slight difference will result in a large RSD.

Blanks

Most results for analyses of blank samples were “below reporting limits,” or less than 3 uS (microsiemens) for specific conductivity (Table 16). Blanks were not measured for temperature, dissolved oxygen, pH, or fecal coliform bacteria.

Protocols specify that one dissolved metals blank sample should be submitted annually from each run that collects metals. In WY 2011, we failed to collect dissolved metals blanks from the eastern Washington runs.

Historically, blanks for dissolved zinc frequently (43% of the time) exceeded reporting limits of 1 ug/L (though results were always < 5 ug/L, the reporting limit for total zinc). As a result, we set the quality code field = 4 for detected dissolved zinc results < 5 ug/L. The effect of this action is that our low-level zinc data on the Internet will be annotated with the footnote: “Asterisk * indicates possible quality problem for the result. You may wish to discuss the result with the station contact person.”

All conductivity blanks were less than 3 uS/cm, except one equal to 3 uS/cm and one equal to 10 uS/cm. We confirmed the latter and traced it to contaminated blank water.

Manchester Laboratory staff assessed the remaining elements of the laboratory QA program through a manual review of laboratory QC results including check standards, in-house matrix spikes, and laboratory blanks. Results were within acceptable ranges as defined by the laboratory’s *Quality Assurance Manual* (MEL, 2006) or were either re-run or coded as determined by laboratory staff (e.g., as an estimate, “J”).

Table 15. Average relative standard deviation (RSD) of replicate samples collected in Water Year 2011.

Results not meeting (exceeding) QAMP MQO criteria (Hallock, 2012) are shown in bold.

Parameter (units)	Precision MQO (%)	Sequential Sample RSD (%)	*n*[a]	Field Split RSD (%)	*n*[a]
Carbon, total organic	10	2.5	22	1.9	21
Carbon, dissolved organic	10	4.9	18	2.2	16
Specific conductance	10	0.88	55	No field splits	
Fecal coliform bacteria (>20 colonies /100 mL)	≥50% < 20 ≥90% < 50	52.9[b] 94.1[b]	17 17	No field splits

Turbidity	15	8.2	57	No field splits	

[a] "*n*" is the number of sample pairs.

[b] Percent of sample pairs (excluding pairs with an average ≤20 colonies/100mL) with RSD < 20% or 50%.

Table 16. Results of field process blank (de-ionized water) samples.

Parameter	Reporting Limit	Number Above Reporting Limit (concentration)	Sample Size *n*
Metals (ug/L)	Various	0 [a]	53
Carbon, dissolved organic (mg/L)	1	2 (1.3 and 1.0 mg/L)	11
Carbon, total organic (mg/L)	1	0	6
Hardness (mg/L)	0.3	0	3
Ammonia (ug/L)	10	0	13
Nitrate+nitrite-nitrogen (ug/L)	10	0	13
Soluble reactive phosphorus (ug/L)	3	0	13
Specific conductivity (uS/cm)	NA	NA (mean: 2.2 uS, std dev: 6.7) [b]	9
Suspended solids (ug/L)	1	0	10
Total nitrogen (ug/L)	25	0	13
Total phosphorus (ug/L)	5	0	13
Turbidity (NTU)	0.5	0	10

NA: not applicable.
[a] Excludes 1 estimated ("J") dissolved zinc result at the reporting limit.
[b] Results from one conductivity blank were 10 uS/cm. This was confirmed and traced to contaminated blank water.

Continuous Temperature Monitoring

Pre- and post-deployment calibration checks using a certified reference thermometer met or were better than the specified criteria for the instruments (Ward, 2005).

Most of the temperature loggers were deployed by July 13. Four eastern Washington loggers were deployed on August 2 (nearly three weeks late).

Continuous Multiple-Parameter Monitoring

Some deployments extended beyond the water year reviewed in this annual report; however, for continuous multiple-parameter monitoring, we reviewed all data from each location except 08C110, Cedar River near Landsburg. Data collection there is intended to be continuous so each water year will be reviewed independently.

Deployments at two locations, 41A070-Crab Cr near Beverly and 59C060-Sheep Cr @ Deer Cr Rd, failed QC requirements for all parameters due to sedimentation. We rejected all data from all deployments at these locations. Sedimentation occurred almost immediately after monthly maintenance. Both deployments were "stand-alone" (i.e., not telemetered), illustrating the usefulness of telemetry, where problems can be identified and corrected relatively quickly.

Data from IMW stations were not processed in time to be included in this QC review, which is performed after visually reviewing data and removing anomalous data points.

Dissolved Oxygen

All of the Hydrolab® dissolved oxygen sensors passed QC requirements (Table 17). Four of the 12 deployments needed a small constant adjustment (offset) to account for probable calibration error. Most sensors were extremely stable, with little or no drift over the course of the deployment, however, there were indications of positive drift during one deployment.

Though oxygen sensors were generally quite "clean," unexplained spikes occurred at times. These spikes usually occurred as a sharp and obvious change rather than a gradual one, and so were easy to spot and remove prior to the numerical QC review reported in Table 17.

On the whole, the RSD between the optical dissolved oxygen sensor results and Winkler results is only a little greater than the RSD between sequentially collected Winkler grab samples (Table 14).

Table 17. Quality control (QC) results from continuous multiple-parameter monitoring.

Average and RSD were calculated after applying offset and removing rejected data. A positive average percent difference indicates that check samples were higher than matching continuous results. Rejected deployments and data considered "unreliable estimates" are in bold.

Station	Deploy-ment End	Offset[a]	Average Percent Difference	RSD	Comment
Dissolved Oxygen (mg/L)					
08C110	All	None	1.44%	1.0%	
13A060	7/20 1315	+0.24	0.0%	0.0%	Code "estimate" because only one valid check sample.
	11/7 1315	+0.46	0.04%	1.12%	Indication of positive drift but within QC criteria after applying constant offset. After adjusting offset, adjusted drift by lowering start 0.13 and raising end 0.12 mg/L.

	10/17 1530		11.1%	8.28%	**Reject data**. Check sample requires excessive adjustment (0.84 std units).
25G060	8/16 0815	+0.15	0.00%	1.85%	One of 3 grab samples was inconsistent (same grab as dissolved oxygen). Difference from grabs ranges from +0.36 to -0.23. Code as "**unreliable estimate**".
	10/31 1230	+0.19	0.00%	0.09%	Indications of drift after 2nd QC check. Code data after 9/13 0830 as "**unreliable estimate**".
37J060	8/10 1145	None	0.13%	0.96%	
	10/12 1200	None	1.20%	0.84%	

[a] Constant added to continuous data only if original average percent difference was >2.0%.

Temperature

The temperature signal from all sensors was both stable and clean. In most cases, precision was excellent, much less than the allowed ±0.4 ºC difference between grab sample temperatures and recorded temperatures.

Conductivity

Only one conductivity deployment exhibited an apparent drift (13A060), and the amount of drift was small. To bring continuous data in line with check sample results, seven deployments required a small positive adjustment, one a small negative adjustment, and 4 required no adjustment. We rejected part of the dataset from 25G060 because the check sample conductivity was inconsistent with other check samples relative to the continuous record, though this may have been a problem with the check sample rather than with the continuous data.

The conductivity sensors exhibited more apparent noise than oxygen or temperature sensors. Noise was usually expressed as a single unusually high value, though sometimes the value would be unusually low.

pH

Although pH was not a critical parameter for this monitoring, and was included only because most of the instruments included pH sensors, resolving the Category 2 designation for pH at two stations (37J060 and 59C060) was included in our objectives. Unfortunately, we rejected most pH data because of imprecision relative to grab sample pH and especially because of drift in the pH signal. The pH datasets from 37J060 are among the few deployments we did not reject.

We have subsequently discovered electrical interference, in some cases, from the metal housing in which we deploy our instruments. If pH is a critical parameter, protective housings should not be made of metal. Long-term continuous monitoring for pH may be possible, but obtaining reliable data will require telemetry, regular maintenance of the pH sensors, maintenance of battery voltage, and regular check samples.

Lake Monitoring

The average RSD from lake monitoring duplicate results was 3.7%, well below the MQO of 20% (Bell-McKinnon, 2011). RSDs for individual duplicate pairs were also low (Table 18).

Table 18. Quality control (QC) results from lake total phosphorus sampling (mg/L).

Lake	Date	Result	Duplicate	Duplicate Type	RSD
Arrowhead (Mason)	7/5/2011	0.0147	0.0151	Field Duplicate	1.9%
Clear (Thurston)	9/23/2011	0.0331	0.0321	Lab Split	2.2%
Florence (Pierce)	5/6/2011	0.0092	0.0099	Lab Split	5.2%
Lone (Island)	8/10/2011	0.1160	0.1270	Field Duplicate	6.4%
Silver (Cowlitz)	6/21/2011	0.0315	0.0310	Field Duplicate	1.1%

Manchester Laboratory QC results were within the specifications provided in laboratory QC guidance (MEL, 2006).

We consider QC results to be acceptable; data may be used without qualification beyond those applied by Manchester Laboratory.

Total phosphorus results and Secchi depth data were entered into EIM and independently reviewed for transcription errors.

Conclusions and Recommendations

Following are conclusions and recommendations resulting from this Water Year (WY) 2011 study by Ecology's River and Stream Monitoring Program.

Conclusions

- Most quality control results were within the limits specified in our Quality Assurance Management Plan and were consistent with findings in previous years.
- Except where noted otherwise, data collected can be used without qualification.
- With the exception of one mercury result, metals data from the Similkameen River were consistent with previous metals monitoring there.

Recommendations

- Stand-alone, multiple-parameter monitoring can be successful but requires regular maintenance to ensure everything is functioning properly and the monitoring results are not affected by debris, silt, or aquatic growth. Telemetered systems, which can be routinely checked in a few minutes at the office, should be used whenever possible and always if data loss is unacceptable.
- If pH is a critical continuous parameter, then to prevent static charge from affecting readings, protective housings should not be made of metal. Long-term continuous monitoring for pH may be possible, but obtaining reliable data will require telemetry, regular maintenance of the pH sensors, close attention to battery voltage, and regular and frequent check samples.
- The continuous temperature monitoring program should continue to expand the deployment period to year-round at all ambient stations. Longer datasets are needed to assess applicable supplemental temperature criteria and to help monitor climate changes.

Appendix B. Historical Changes in Sampling and Laboratory Procedures, as well as Large-Scale Environmental Changes Potentially Affecting Water Quality

This appendix provides a record of changes in methods and procedures used by Ecology's Freshwater Monitoring Unit to collect and analyze river and stream water quality data. Other environmental changes that may potentially affect water quality over a large area are also recorded here.

Many of the changes listed here are anecdotal and may or may not have affected data quality. Comments prior to October 1988 are based on interviews with individuals involved with the earlier program. Comments after that date have usually been recorded as the changes occurred.

General

- Jun to Sept 1985: Laboratory moved from Ecology's Southwest Regional Office to Manchester.
- Oct 1988: Implemented QA/QC program (See memo from David Hallock, October 17, 1988.)
- Prior to WY91: Samples were sent to contract labs from time to time. These occurrences are not all recorded here. Records are not detailed and only available from bench sheets archived by Manchester Laboratory.
- 1994: The use of Polyacrylamide (PAM) to control erosion from rill irrigation is becoming widespread in eastern Washington. Water quality effects are unknown.
- 1996: Began monitoring discharge at some stations ourselves (mostly basin stations), rather than contracting with USGS.
- 2001: Began running Central (Nov 2001) and Eastern (Feb 2002) runs out of regional offices. Barometric pressures calculated from airport readings, either uncorrected, if available, or re-converted to sea level.
- Jan-Jun 2002: Some barometric pressures collected from the western part of the state may be off by 1.0 mmHg due to calibration errors. The effect of this amount of error on the percent oxygen saturation calculation is insignificant.
- Oct 2005 (except the NW run, which made the change several months earlier): Previously, aliquots for pH, conductivity, and turbidity were obtained from the stainless steel bucket used to collect the oxygen. However, this presented a risk of contamination from the oxygen bottles. The sampler was re-designed so that only the oxygen sample is obtained from the bucket; all other samples are collected in passengers.
- Nov 2007: Implemented a Freshwater Technical Coordination Team-required "ride-along" procedure where a senior staff rides with each sampler once during the year to ensure SOP are followed uniformly.
- Jan 16, 2008: Implemented semi-annual calibration of Operation's Center digital barometer against Hg barometer in Air Lab at HQ. Digital BP read 30.86 before recalibration and 30.54 after. S, N, and W BP data since October 2006 could be up to 0.32 inches Hg high.
- Oct 1, 2010: Changed blank sample procedures. Previously, we added blank water to sample equipment then processed the water as a regular sample. Now, we are lowering the sample equipment from the bridge (without entering the water). This should capture potential contamination falling off the bridge during sampling.

Nutrients

- General: Prior to 1980, USGS labs analyzed samples.
- 1966-1969: One gallon of sample was collected in glass jars and held at room temperature for indefinite periods without preservative.
- 1970-1973: Unknown methods; may have been preserved with HgCl. Filtered in field.
- 1973: Laboratory moved from Tacoma to Salt Lake City.
- 1973-1974: Chilled, no preservative. Held as long as one week. Filtered in field; kept in brown poly bottle.
- 1972-1974?: For a short time, TP and NO3 may have been added by filters (probably 72-74). (Personal communications with Joe Rinella, USGS).
- Sep 30, 1978: USGS Lab moved to Arvada, CO. Joint program samples sent there; samples collected for Ecology project only may have been analyzed in-house.
- ~1978: Chilled. Brown poly bottle? (the brown poly bottle may have been introduced later). 30-day holding time for NO2+NO3 implemented (status of other nutrients is unknown). (Source of methods prior to 1979: pers. comm. Joe Rinella, USGS, and Skinner, Earl L. "Chronology of Water Resources Division activities that may have affected water quality values of selected parameters in Watstore, 1970-86. Provisional Report Feb 1989.)
- 1979: For a while, the USGS lab reported nutrient results to the nearest 0.01 units. Values below 0.005 were reported as 0.00. USGS decided to change all Watstore data = 0 to 0.01K back to 1973 for NO2+NO3. Decision on other nutrients is unknown, but they may also have been changed. Most of the 0s in our database have been converted to 0.01K (K-below the detection limit) but a few 0s may remain in the older data.
- 1980: USGS requires NO2+NO3 be preserved with HgCl. Status of other nutrients is unknown. Ecology requirements are unknown.
- Jun 1, 1980 to 1986: Nutrients analyzed by Pat Crawford at Southwest Regional Office.
- Aug 1985: High phosphate values, presumably a result of lab error. (Coded '9-do not use' in our database). (See "Trends in Puget Sound," 1988, Tetra Tech, App. B.)
- 1986 to Apr 1987: Analyzed by various people, mostly Helen Bates, Steve Twiss, and Wayne Kraft at Manchester.
- Jun 1985: Switched from Technicon to Rapid Flow Analysis (Alpkem) auto-analyzers.
- Apr 1987 to present: Analyzed by various people at Manchester.
- Jan 1987 to Jul 1987: NO3, NH3, and TP analyzed by contract lab.
- Mar 1990: Began using MFS cellulose acetate filters for field filtration of nutrients. Previously use Millipore, type HA (cellulose nitrate?).
- Sep 17 - Oct 12, 1990: All nutrient samples were contracted out.
- Oct 1990: Dissolved ammonia (P608) and dissolved nitrate+nitrite (P631) were added to the Marine network. Totals (P610 and P630) were dropped.
- Feb 1991: All nutrients sent to contract lab.
- Mar 1991: All nutrients sent to contract lab.
- ~1993: Began collecting nutrients in acid-washed poly-bottle passenger rather than in the stainless-steel bucket used for oxygen determinations.
- Jul 1994: The phosphorus content in laundry detergents is restricted to 0.5% and dishwashing detergent to 8.7% statewide (SSB 5320; WAC 70.85L.020). Phosphorus use had been limited in Spokane County one (?) year earlier.
- Feb 1999: Manchester Laboratory switched from manual to inline digestion for total phosphorus. In early 2003, during the course of evaluating a different method for phosphorus analysis, Manchester Laboratory discovered that the in-line method contained a high bias (4 to

20 ppb). Trend analyses of total phosphorus data should be interpreted carefully if results collected between Feb 1999 and Sept 2003 are included. (See email from Dean Momohara to David Hallock, 31 March 2003.) Total phosphorus data analyzed using this method have been coded "4" indicating a potential quality problem, and given a different name ("TP_PInline" rather than the usual "TP_P").

- Sep 2000: Nitrate+nitrite method nomenclature changed from EPA 353.2 to SM 4500NO3I because the latter method is more specific. The instrument used was changed at around this time from a "Flow analyzer" to a "Flow Injection" instrument and procedures may have changed slightly.
- Before Jul 2001: Ammonia method nomenclature changed from EPA 350.1 to SM 4500NH3H because the latter method is more specific. The instrument used was changed at around this time from a "Flow analyzer" to a "Flow Injection" instrument and procedures may have changed slightly.
- Before Aug 2001: Ortho-phosphorus method nomenclature changed from EPA 365.3M to SM 4500PG because the latter method is more specific. The instrument used was changed at around this time from a "Flow analyzer" to a "Flow Injection" instrument and procedures may have changed slightly.
- Before May 2000: Total nitrogen method nomenclature changed from VALDERRAMA to SM 4500NB because the latter method is more specific. The instrument used was changed at around this time from a "Flow analyzer" to a "Flow Injection" instrument and procedures may have changed slightly.
- Oct 2000: TP method changed from EPA 365.1 to SM4500PI. The former method specifies a manual digestion, while the latter correctly refers to the in-line digestion used by Manchester Laboratory's Lachat instrument.
- Oct 2000 to Feb 2001: A low bias may apply to TN data. Except for December data, Manchester Laboratory deemed the bias to be small enough that the data did not need to be qualified. December TN results were coded as estimates (See email from M. Lee to David Hallock, March 8, 2001.)
- Oct 2003: TP method changed from SM4500PI to EPA 200.8M, an ICP/MS method with low detection limits and without the bias associated with in-line digestion. Samples are collected in a 60mL container with HCl preservative instead of the earlier 125mL container with H_2SO_4 preservative.
- Oct 1, 2007: We changed total phosphorus analytical methods from EPA200.8M (ICP-MS) to SM4500PH (colorimetric with manual digestion). We made this change because we discovered that at turbidities greater than 4 NTUs, the ICP method is biased low compared to the colorimetric method. (See email from Dave Hallock to Bob Cusimano, October 25, 2007.)
- Jan 15, 2008: OP method changed from SM4500PG to SM4500PF and TOC method changed from EPA415.1 to SM5310B. Neither procedure actually changed.
- Jul 2008: The phosphorus content in dishwasher detergents is restricted in ~~certain counties~~ Spokane County ~~depending on population~~ as of this date (RCW 70.95L.020). (A new law signed in March, 2008, eliminated Clark County from the July 1 deadline and weakened regulations that will start in Whatcom County. Phosphorus in laundry detergents has been restricted since 1994.)
- Jul 2010: The phosphorus content in dishwasher detergents will be restricted statewide as of this date (RCW 70.95L.020).

Suspended Solids

- General: Filters were usually used, but sometimes Gooch crucibles were used.
- Feb 1978: Began collecting as passenger to oxygen sampler (was previously collected as aliquot of oxygen sampler). (See memo from Bill Yake, 30 Jan 1978 and Ambient Monitoring Procedure-1978(?) notebook.)
- Mid-1985: Amount filtered changed from 250 (?) to 500 ml.
- Sep 17 - Oct 12, 1990: Suspended sediment samples were contracted out.
- Apr 1991: Began collecting 1000 ml of sample.
- Jul 2002: A number of suspended solids results entered into our database as '0' were deleted. We do not know if these results were below reporting limits or "missing data"; 138 results collected between 1972 and 1981 were affected.
- Mar 2003: TSS method reference changed from EPA160.2 to SM 2540D. Methods did not change; the latter reference more accurately reflects analytical procedures. See email from Feddersen, Karin, March 24, 2003.

Conductivity

- Feb 1978: Began calibrating twice monthly using 40, 70, 140, and 200 umho/cm standards. (See memo from Bill Yake, 30 Jan 1978 and Ambient Monitoring Procedure-1978(?) Notebook)
- Oct 1991: All meters were re-calibrated Oct 11, 1991. One conductivity meter was not calibrated above 500 umhos/cm (and could not be calibrated). This meter had last been calibrated about 1 year earlier. Most meters read higher than the 100 umhos/cm standard.
- Oct 1994: Switched from Beckman model Type RB-5 (which could not be field calibrated) to Orion Model 126 meter, calibrated daily.
- 1998: Orion meter calibration began drifting during the day. Sometimes meter could only be calibrated to within 4 umhos/cm of the standard. At first, some samplers would correct the data, others would not. Now, these data are uncorrected and coded "J" (estimate).
- Oct 1, 2011: Dropped Orion model 126 meter and started using Hach model HQ40d combination meter for both pH and conductivity.

Fecal Coliform Bacteria

- Early 1980s: Field personnel may have analyzed some samples.
- Oct 7, 1975 to Nov 1981: Fecal data from eastern Washington may be questionable during this period.
- 1980 to Mar 1988: No changes; analyzed by Nancy Jensen and others at Manchester. However, there is an apparent drop in monthly geometric means in late 1985. The may be coincident with moving the lab to Manchester (see memo from Dave Hallock to Dick Cunningham, June 18, 1991).
- Mar 1988: Switched to new filter with slightly better recovery.
- Nov 2000: Holding time was changed from 30 hours to 24 hours (Standard Methods changed to 24 hours with the 17^{th} edition, 1989). As a result, more data have been coded "J" since then due to exceeding holding times.
- Sep 2003: FC method reference changed from SM 16-909C to SM 9222D. Methods did not change; the latter reference more accurately reflects analytical procedures. See email from Feddersen, Karin, September 15, 2003.

- ~Aug 2009: Pasco airport began x-raying water samples. Other airports may follow suit eventually. Exposure is < 1 millirad while doses used to kill bacteria on food are >30,000 rads. An unnamed contact at Washington's Department of Health stated that the dose is not a concern. We considered testing for an effect, but the number of samples required to detect a small effect is prohibitively large given the natural variance in bacteria data.

Turbidity

- 1970s: EPA specified a 2100A turbidimeter. Formerly, turbidity units were FTU (?)
- Jan 1976: Turbidity units changed from Jackson Turbidity Units (JTU) to Nephelometric Turbidity Units (NTU). (Source: review of historical reports.) These are roughly equivalent when greater than 25 JTU/NTU, otherwise not.
- Sep 1993: Lab began using a new turbidimeter, Hach model "Ratio X/R."
- Jan 2003: In our database, the units for turbidity results collected prior to January were changed from NTU back to JTU. Though roughly equivalent at JTUs > 25, these are not equivalent for lower measurements; the original units should have been retained.

Field pH

- Oct 7, 1975 to Nov 1981: pH data from eastern Washington are questionable during this period.
- Feb 1978: Began calibrating meter twice monthly. Previous procedures unknown. (See memo from Bill Yake, 30 Jan 1978 and Ambient Monitoring Procedure-1978(?) notebook)
- 1986: Changed to Beckman digital pH meter with gel probe.
- Dec 1991: Changed to Orion model 250A meter with "spare water" liquid probe (uses 1M KCl, rather than 4M). Calibrate daily and check calibration three times during the sampling day.
- Oct 1, 2011: Dropped Orion model 250A meter and started using Hach model HQ40d combination meter for both pH and conductivity. See the WY2011 Annual Report for results of a method comparison study.

Temperature

- Feb 1978: Switched from thermometer in bucket to thermistor in river. (See memo from Bill Yake, 30 Jan 1978 and Ambient Monitoring Procedure-1978(?) notebook.)
- Feb 1985: Checked thermistor calibration daily (internal calibration check based on red-lining needle, not a check against a NIST thermometer) (Memorandum from John Bernhardt, Feb 7, 1985).
- Spring 1994: Switched to YSI 300 meter (precision +/- 0.4C).
- Jan 1, 2001: Began calibrating thermistors prior to each run rather than annually. Some thermistors were found to be as much as 1-2 °C low.
- About May 2006: Began evaluating thermistor calibration at several temperatures and calculating correction coefficients based on a linear regression correction. Corrections are applied upon data entry by the database rather than by the sampler.

Oxygen

- Oct 1, 1977: Began measuring barometric pressure to calculate percent saturation. Previous saturation calculations were presumably based on elevation.

- Mar 1989: Began applying correction factor to results of Winkler analyses based on titration with sodium biiodate to correct sodium thiosulfate normality to 0.025. Previously, thiosulfate was standardized upon preparation, but not during use.

Barometric Pressure

- Feb 1985: Began calibrating barometer before each run based on National Weather Service report from Olympia airport (Memorandum from John Bernhardt, Feb 7, 1985).
- 1995: Began calibrating barometer prior to each run using an on-site mercury barometer rather than pressure as reported by the Olympia airport.
- 2003: Began calibrating barometer prior to each run using an on-site digital barometer rather than the mercury barometer. Calibrating digital barometer to mercury barometer annually.
- Jan 2008: Began calibrating on-site digital barometer twice yearly against a mercury barometer.
- ~Apr 2011: Evaluated historical data against elevation-based BP and adjusted quality codes for some data points. Implemented BP QC check which compares BP during data entry to expected BP based on elevation.

Chlorophyll

- Mar 15, 1990: Switched to fluorometric method (from spectrophotometric). New method has lower detection limit (0.02 ug/L) but less precision. (See memo from Despina Strong, April 12, 1990.)

Hardness

- Jul 1, 1991: Began using 125 ml bottle with HNO3 as preservative. (Previously, aliquot from unpreserved general chemistry bottle was used.)

Metals

- May 1994: Implemented low-level dissolved metals monitoring at selected stations. Metals results prior to this date are questionable unless well above detection limits and have been quality-coded “9” in our database so that they will not routinely be retrieved. Quality problems include inconsistent blank correction and indications of simultaneous peaks and troughs in data series from unrelated stations for results above reporting limits.
- Apr 2010: A review of historical blank data showed that dissolved zinc exceed reporting limits of 1 ug/L 43% of the time (though never greater than 5 ug/L). As a result, we have decided to set the quality code field = 4 for reported dissolved zinc results < 5 ug/L, which indicates a potential data quality issue.

Flow

- Oct 1, 2009: Began recording uncorrected stage, correction, and error estimate.
- Feb 2011: Processing of flow for ambient stations shifted from Howard Christensen to Jason Myers. Prior to this time, flows below some dams (e.g., Grand Coulee) were miss-calculated. (These flows have been corrected.)

- Oct 2011: Decided to remove flows from the web (and replace with a link to our source, typically USGS, USACOE, or in-house) and code flows in EIM “Instantaneous flow based on provisional data obtained from various sources. Not confirmed.” We also developed procedures to automate retrieval of flow data and to document and manage metadata used for determining flow (e.g., time of travel correction).

This page is purposely left blank

Appendix C. Water Year 2011: Sources of Raw Data

Data discussed in this report are available in electronic format through various sources:

1. Ambient river and stream monitoring data are available on Ecology's web pages (www.ecy.wa.gov). Look under "Programs," "Environmental Assessment", and "River and Stream Water Quality."

2. Data are available in Ecology's Environmental Information Management (EIM) system. From Ecology's main page (www.ecy.wa.gov), look under "Scientists," "Environmental Monitoring Data", and "EIM." Our project IDs are listed in Table C-1.

Table C-1. Ambient Monitoring EIM projects.

Project ID	Description	Status	Start Date
AMS001	Statewide River and Stream Ambient Monitoring-WY2010 to present (published data)	ONGOING	10/1/2009
AMS001-2	Statewide River and Stream Ambient Monitoring-WY2011 to present (provisional data)	ONGOING	10/1/2009
AMS001B	Statewide River and Stream Ambient Monitoring-Pre-1980	COMPLETED	1/1/1949
AMS001C	Statewide River and Stream Ambient Monitoring-1980 to WY1988	COMPLETED	1/1/1980
AMS001D	Statewide River and Stream Ambient Monitoring-WY1989 through WY1999	COMPLETED	10/1/1988
AMS001E	Statewide River and Stream Ambient Monitoring-WY2000 through WY2009	COMPLETED	10/1/1999
AMS002	Statewide Lake Monitoring	COMPLETED	1/1/1989
AMS002B	Lake Mini-Monitoring (published data)	ONGOING	1/1/2010
AMS002B-2	Lake Mini-Monitoring (provisional data)	ONGOING	1/1/2011
AMS004	Continuous Stream Monitoring	ONGOING	6/1/2001

3. Data are available by contacting the ambient monitoring staff person responsible for ambient monitoring in the Washington State Department of Ecology region, currently:

- Ecology Central Region: Dan Dugger (509.454.4183; ddug461@ecy.wa.gov)
- Ecology Eastern Region: Jim Ross (509.329.3425; jros461@ecy.wa.gov)
- Ecology Northwest Region: Bill Ward (360.407.6621; bwar461@ecy.wa.gov)
- Ecology Southwest Region: Bill Ward (360.407.6621; bwar461@ecy.wa.gov)

The first two digits of each station number is the Water Resource Inventory Area (WRIA) number. This number can be used to identify which Water Quality Management Area (WQMA) or "basin" each station is in, according to Table C-2.

Table C-2. Washington's Water Quality Management Areas.

Basin	WRIAs		Basin	WRIAs
Cedar/Green	8-9		Nooksack/San Juan	1-2
Columbia Gorge	27-29		Okanogan	48-53
Eastern Olympics	13-14, 16-19		Puyallup/Nisqually	10-12
Esquatzel/Crab Cr	36, 42-43		Skagit/Stillaguamish	3-5
Horseheaven/Klickitat	30-31		Spokane	54-57
Island/Snohomish	6-7		Upper and Lower Snake	32-35
Kitsap	15		Upper Columbia/Pend Oreille	58-62
Lower Columbia	24-26		Upper Yakima	38-39
Lower Yakima	37		Wenatchee	40, 44-47
Mid Columbia	41		Western Olympics	20-23

Ambient Monitoring Data Remarks Codes

Remarks codes in historical data are defined below. Only "U" and "J" were used in WY 2011.

B,V Analyte was found in the blank, indicating possible contamination.
E Result is an estimate due to interference.
G, L True result is equal to or greater than reported value.
H Sample was analyzed over holding time.
J The reported result is an estimate.
K, U The analyte was not detected at or above the reported result.
N Spike sample recovery was outside control limits.
P Result is between the detection limit and the minimum quantitation limit (applied to metals).
S Spreader: one or more bacteria colonies were smeared, possibly obscuring other colonies.
X High background count of non-target bacteria, possibly obscuring additional colonies.

Appendix D. Water Year 2011: Missing Data

Table D-1. Missing data for the 12 standard parameters.
"X"=missing

Appendix E. Glossary, Acronyms, and Abbreviations

Glossary

A**mbient:** Background or away from point sources of contamination.

Anadromous: Types of fish, such as salmon, that go from the sea to freshwater to spawn.

Anthropogenic: Human-caused.

Basin: A drainage area or watershed in which all land and water areas drain or flow toward a central collector such as a stream, river, or lake at a lower elevation.

Bi-monthly: Every other month.

Char: Char (genus *Salvelinus*) are distinguished from trout and salmon by the absence of teeth in the roof of the mouth, presence of light colored spots on a dark background, absence of spots on the dorsal fin, small scales, and differences in the structure of their skeleton. (Trout and salmon have dark spots on a lighter background.)

Conductivity: A measure of water's ability to conduct an electrical current. Conductivity is related to the concentration and charge of dissolved ions in water.

Diel: Of, or pertaining to, a 24-hour period.

Dissolved oxygen: A measure of the amount of oxygen dissolved in water.

Exceeded: Did not meet.

Fecal coliform: That portion of the coliform group of bacteria which is present in intestinal tracts and feces of warm-blooded animals as detected by the product of acid or gas from lactose in a suitable culture medium within 24 hours at 44.5 plus or minus 0.2 degrees Celsius. Fecal coliform are "indicator" organisms that suggest the possible presence of disease-causing organisms. Concentrations are measured in colony forming units per 100 milliliters of water (cfu/100 mL).

Geometric mean: A mathematical expression of the central tendency (an average) of multiple sample values. A geometric mean, unlike an arithmetic mean, tends to dampen the effect of very high or low values, which might bias the mean if a straight average (arithmetic mean) were calculated. This is helpful when analyzing bacteria concentrations, because levels may vary anywhere from 10 to 10,000 fold over a given period. The calculation is performed by either: (1) taking the nth root of a product of n factors, or (2) taking the antilogarithm of the arithmetic mean of the logarithms of the individual values.

Grab sample: A discrete sample from a single point in the water column or sediment surface.

Hardness: A measure of the dissolved solids in a water sample (e.g., calcium, magnesium).

Noise: An unwanted perturbation to a wanted signal. Noise is used here to indicate any result not representative of the environmental conditions being monitored.

Nutrient: Substance such as carbon, nitrogen, and phosphorus used by organisms to live and grow. Too many nutrients in the water can promote algal blooms and rob the water of oxygen vital to aquatic organisms.

Parameter: A physical chemical or biological property whose values determine environmental characteristics or behavior.

pH: A measure of the acidity or alkalinity of water. A low pH value (0 to 7) indicates that an acidic condition is present, while a high pH (7 to 14) indicates a basic or alkaline condition. A pH of 7 is considered to be neutral. Since the pH scale is logarithmic, a water sample with a pH of 8 is ten times more basic than one with a pH of 7.

Salmonid: Fish that belong to the family *Salmonidae*. Basically, any species of salmon, trout, or char. www.fws.gov/le/ImpExp/FactSheetSalmonids.htm

Sinusoidal: An oscillation that can be described with a sine function.

Spatial: How concentrations differ among various parts of the river.

Stage height: Water surface elevation.

Synoptic survey: Data collected simultaneously or over a short period of time.

Temporal: Characterize over time (e.g., temporal trends).

Thermistors: Data loggers.

Total maximum daily load (TMDL): A distribution of a substance in a waterbody designed to protect it from exceeding water quality standards. A TMDL is equal to the sum of all of the following: (1) individual wasteload allocations for point sources, (2) the load allocations for nonpoint sources, (3) the contribution of natural sources, and (4) a margin of safety to allow for uncertainty in the wasteload determination. A reserve for future growth is also generally provided.

Total suspended solids (TSS): Portion of solids retained by a filter.

Trend: A change over time.

Turbidity: A measure of water clarity. High levels of turbidity can have a negative impact on aquatic life.

Water Year (WY) 2011: October 1, 2010 through September 30, 2011.

Watershed: A drainage area or basin in which all land and water areas drain or flow toward a central collector such as a stream, river, or lake at a lower elevation.

7-DADMax: Seven-day average of the daily maximum (usually temperature).

7-DADMin: Seven-day average of the daily minimum (usually oxygen).

Acronyms and Abbreviations

BP	Barometric pressure
DQO	Data quality objective
DNR	Washington State Department of Natural Resources
Ecology	Washington State Department of Ecology
EIM	Environmental Information Management database
IMW	Intensively Monitored Watersheds
EPA	U.S. Environmental Protection Agency
MQO	Measurement quality objective
NA	Not applicable
NF	North Fork
NO_2+NO_3	Nitrate + nitrite-nitrogen
QA	Quality assurance
QAMP	Quality Assurance Management Plan
QC	Quality control
RMS	Root mean square
RSD	Relative standard deviation
SF	South Fork
SM	Standard method
SOP	Standard operating procedure
Std dev	Standard deviation
TMDL	(See Glossary above)
TN	Total nitrogen
TP	Total phosphorus
TSS	(See Glossary above)
USGS	U.S. Geological Survey
WAC	Washington Administrative Code
WQI	Water Quality Index
WRIA	Water Resource Inventory Area
WY	(See Glossary above)

Units of Measurement

°C	degrees centigrade
cm	centimeter
mg/L	milligrams per liter (parts per million)
mL	milliliters
NTU	nephelometric turbidity units
s.u.	standard units
ug/L	micrograms per liter (parts per billion)
uS	microsiemens per centimeter, a unit of conductivity
