FROM: David Hallock DH
SUBJECT: Results of the 1990 Water Quality Index Analysis

This memo describes the Water Quality Index (WQI), records the procedures used to produce the 1990 WQI, and presents the results of the analysis.

Introduction

The WQI is a unitless number, ranging from 0 to 100, which is derived primarily from data collected by the Ambient Monitoring Section (AMS) of Environmental Investigations and Laboratory Services (EILS); however, data collected by USGS, METRO, and USBR were also used in the 1990 analysis. Scores are determined by comparing measured values to specified criteria. Criteria were developed by a national study group and modified to better evaluate Washington's water quality. In general, the criteria are based on Washington State Water Quality Standards for Class A waters. The following variables were included in the 1990 WQI:

- | | |
|-----------------------|------------------------|
| 1. Temperature | 2. Oxygen |
| 3. Bacteria | 4. pH |
| 5. Turbidity | 6. Nutrients (N and P) |
| 7. Suspended Sediment | 8. Ammonia Toxicity |

For marine stations, only the first five variables were included.

The higher the WQI, the worse the water quality. For the first four variables above, an index below 20 implies compliance with state Class A standards. For the other variables, state standards do not exist or are not compatible with the WQI analysis. In general, scores between 0 and 20 meet the goals of the Federal Water Pollution Control Act, scores between 20 and 60 are considered marginal, and scores over 60 are unacceptable.

Dick Cunningham

July 18, 1990

Page 2

The WQI is produced for each variable by a computer program developed by Ray Peterson, EPA, Region X. WQIs are determined by converting raw data to an index score based on the criteria curve for that variable. The computer program then calculates a monthly WQI by averaging the data for each month in the period selected. For example, for a three-year period the January WQI would be an average of three Januaries. A monthly overall WQI is calculated by averaging the monthly WQI for each variable with a penalty applied for values over 20, excluding turbidity. The final WQI for a given variable is the average of the WQI's for the highest three consecutive months. The final overall WQI is the average of the highest three consecutive months of the monthly overall WQI.

Procedures Used in the 1990 WQI Analysis

The analyst can determine the variables to be evaluated, the number of years to include in the index, the criteria curve for each variable, and the weight of each variable in the overall WQI. The analyst can also use different criteria curves for different seasons.

For the 1990 analysis, "current" stations had at least one sample per quarter for four consecutive quarters (three consecutive quarters for marine stations) collected any time in the three water years (WY) prior to the analysis (WY 1990). This three-year average masks anomalies in the data set and the effects of low- or high-water years but may also mask actual changes in water quality. The 1988 WQI analysis used five years for current stations but I felt that three years would provide a more accurate assessment of current conditions. "Historic" stations were those with sufficient data in the five years preceding the current period (WY 1982 through 1986). Those stations where no data has been collected since WY 1981 are not included in the 1990 WQI. Historic station WQI's should be used with caution because of possible changes since those stations were sampled last. Monitoring data from USGS, USBR, and METRO were used where available. If data from both Ecology and another agency were available, the data was aggregated from both data sets prior to running the analysis.

I used the same criteria curve for a given variable as was used in the 1988 analysis. The actual curves used are available on request. Most variables have several criteria curves (for example, one for cold water, one for warm water, one for spawning and rearing, etc.) In general, only the cold water curve corresponds to state standards.

All variables were weighted equally in determining the overall WQI. That is, temperature, for example, was not considered more important than turbidity. Nutrients and suspended sediment were compared to more stringent standards from June through October and less stringent standards from November through May. Some streams were

Dick Cunningham
July 18, 1990
Page 3

designated as "glacial" which set the maximum WQI for turbidity and suspended sediment at 25.

General Comments

There is great potential for misusing any index. The following points should be considered carefully before interpreting the WQI:

1. An index greater than 20 for temperature, oxygen, bacteria, or pH indicates water quality exceeded state standards at least once and probably several times. Criteria for other variables are not based on standards.
2. Because the WQI is the average of the highest three consecutive months, the index may be below 20 even though violations of standards occurred. Similarly, violations may be masked because the monthly index is an average for the period evaluated.
3. The current station WQI's are, in most cases, based on three years of data. The WQI's do not, therefore, indicate water quality for any given year. The degradation (or improvement) of a stream in WY 1989 may not be reflected in the 1990 WQI. For this reason, trends should not be inferred from successive WQI's without testing against raw data. In addition, a trend analysis based on WQI may be biased because of changes in the procedures used to determine the WQI (standards changes, use of different curves, different periods of analysis, etc.).
4. The overall WQI is not a simple mean but includes a penalty factor for WQI's greater than 20 (excluding turbidity).
5. The WQI is based on data from a single station and in many cases may not be representative of an entire stream. Caution should be used in extrapolating the index to entire basins or sub-basins.

Results

The results of the 1990 Water Quality Index analysis are presented in the attached tables. Table 1 contains the WQI sorted by Water Body Tracking System Number (WBTS). Table 2 contains the WQI sorted by Department of Ecology Region and sub-sorted by Ambient Monitoring Station number. In these first two tables, the approximate area assessed by a particular station is indicated by the segment size (miles

for freshwater stations and square miles for marine stations). Whether or not a station was considered water quality limited in the 1988 305(b) report is indicated in the "WQL in 1988" column. "Comments and possible sources of WQIs greater than 20" is based largely on remarks from Ecology's regional offices. Table 3 contains a listing of the ten stations in the state with the highest WQI (lowest water quality) for each variable.

The South Fork of the Palouse River in Pullman (34B110) had the highest water quality index in the state (WQI = 100), unchanged from the 1988 report. This score, the highest possible, resulted from high bacteria and especially high nutrients. With the exception of turbidity, this station was not on the "worst ten" list for any other variable.

The two Mill Creek (King County) stations had nearly as high a WQI score as the South Fork of the Palouse River, resulting primarily from low dissolved oxygen levels, high fecal coliform bacteria, and high nutrients. These results, from stations at river miles 3.1 and 4.7, indicate significant problems in the lower reaches of Mill Creek.

The 1990 WQI indicated low oxygen problems at more stations than any other variable analyzed. However, of the 56 stations with oxygen WQI's greater than 20, all but six were marine stations. Marine stations are particularly susceptible to high WQI scores for dissolved oxygen because the index is an average of all depths sampled (usually 0, 10, and 30 meters), and does not compensate for the possibility of naturally low oxygen below the photic zone. (Note, however, that the Water Quality Standards for dissolved oxygen in marine waters make no reference to depth.)

Besides oxygen, bacteria and temperature had the most stations with scores greater than or equal to 20 (42 and 40, respectively). In other words, high fecal coliform bacteria and high temperatures were the factors most often responsible for the failure of a station to meet the goals of the Federal Water Pollution Control Act. The total number of stations evaluated was 177.

Recommendations

1. The consistent poor water quality in the South Fork of the Palouse River in Pullman has been discussed in a receiving water survey by Joy (1987). The Ambient Monitoring Section should consider adding stations to its rotating network based on the results of that survey. One possible station is Paradise Creek, the receiving water for the Moscow, Idaho WWTP which Joy identified as the most significant source of nutrients to the upstream reach of the South Fork.

Page 5

2. Adjusting oxygen water quality standards and WQI criteria to account for the effect of depth in marine systems on dissolved oxygen concentrations should be considered.
3. Future WQI reports should discuss the meteorological characteristics of the water years included in the analysis of "current" stations. This is particularly important when only three years of data are used. Whether these years were drier or wetter, or warmer or colder than normal will influence the results of the WQI.
4. The criteria curves used in the WQI were developed more than 10 years ago without documentation. These curves need to be re-evaluated. In addition, consideration should be given for using different curves in different ecoregions (Omernik and Gallant 1986). It is not practical to compare a stream like the Walla Walla River to the same standards as the Nisqually River.

STATE OF WASHINGTON
DEPARTMENT OF ECOLOGY

7171 Cleanwater Lane, Building 8, LH-14 • Olympia, Washington 98504

January 18, 1991

TO: Dick Cunningham
FROM: David Hallock *DA*
SUBJECT: 1990 Water Quality Index Analysis

Table 3 in my memo to Dick Cunningham dated July 18, 1990, (Results of the 1990 Water Quality Index Analysis) incorrectly states that no station had an ammonia toxicity value over 20. In fact, nine stations had ammonia toxicity scores greater than 20. A revised Table 3 is attached.
