ACKNOWLEDGEMENTS

Many people contributed to the success of the Wateryear 1991 program. Special thanks go to the following people:

Sample collection was assisted by Dave Hallock and Wayne Croft for long hours behind the wheel in sometimes less than ideal weather conditions.

Laboratory analyses and support was supplied by Kitty Bickle, Pam Covey, Michelle Elling, Nancy Jensen, Aileen Smith, Craig Smith, Despina Strong, Dave Thomson, Cyma Tupas, and Will White at Ecology's Manchester Environmental Laboratory. Thanks for coping with the seemingly endless supply of samples.

Data management was conducted by Dave Hallock and Bob James.

Technical peer review was conducted by Ken Dzinbal, Dave Hallock, Stewart Lombard, and Steve Saunders of the Department of Ecology; and Chris Prescott of the Puget Sound Water Quality Authority.

ABSTRACT

From October 1, 1990, to September 30, 1991 (Wateryear 1991), the Washington State Department of Ecology (Ecology) Ambient Monitoring Section measured 13 conventional water quality parameters monthly at 81 stations in Washington State. Water quality information from these stations are used to evaluate instream conditions as they relate to Water Quality Standards, detect changes in water quality over time, and provide current water quality information for Ecology's water quality based permitting of dischargers.

In Wateryear 1991, rivers and streams monitored by Ecology's Ambient Monitoring Program exhibited occasional violations of Washington State Water Quality Standards. The majority of these violations involved elevated concentrations of fecal coliform bacteria and increased summer water temperatures. Water quality information collected at the 12 core/bench mark stations within the Puget Sound Basin were selected for more in-depth analysis, including the use of the Seasonal Kendall (SK) Statistical Test for trend detection, and are discussed in more detail. The most significant trends were found on the Lower Green River and reflect substantial water quality improvements that correspond with relocation of the Renton Sewage Treatment Plant Outfall.

PART I:

Program Description and General Statewide Results

INTRODUCTION

The Washington State Department of Ecology (Ecology) has operated a long-term Freshwater Ambient Monitoring Program from Ecology's inception in 1970. The primary objectives of this program are to 1) provide water quality information to determine if designated uses are supported by existing instream water quality (305b Report); 2) track spacial and temporal change in water quality of rivers and streams; and 3) provide site specific water quality information in support of Ecology's water quality based permitting of dischargers.

This report is divided into two parts. Part I presents information on the methods the Freshwater Ambient Monitoring Program used for network design, sample collection, field processing, field and laboratory analysis, data handling, quality assurance/quality control (QA/QC), and data analysis. The data from Ecology's freshwater ambient monitoring network for Wateryear 1991 (WY 1991) are discussed from three perspectives: 1) statewide, 2) rivers and streams within the Puget Sound Basin, and 3) rivers and streams outside of the Puget Sound Basin. Part II presents more detailed analyses of the water quality data collected at core/bench mark stations located inside of the Puget Sound Basin.

METHODS

This section provides information on network design, sample collection, field processing, field/laboratory analysis, data handling, QA/QC, and data analysis techniques.

Network Design

Network design will be discussed as follows: 1) a brief history of the Ambient Monitoring Program; 2) current network design considerations; and 3) a comparison of the proposed Puget Sound Ambient Monitoring Program Inside of Puget Sound Basin to Ecology's Wateryear 1991 Network Inside of the Puget Sound Basin.

Historical

From 1978 to 1990, Ecology's Freshwater Ambient Monitoring Program consisted of a 78-station fixed station network that was sampled monthly. Prior to 1978, various monitoring efforts were undertaken by Ecology and its predecessor agencies ranging from monthly fixed station to bi-monthly rotating station networks. The specific monitoring locations and the years they have been monitored are presented in Appendix 1.

Current

For Wateryear (WY) 1991 (October 1, 1990, to September 30, 1991), Ecology developed a new monitoring network comprised of three types of stations: 1) core/bench mark, 2) rotating, and 3) floating.

This new network design allows Ecology to collect more water quality information with the same level of effort, however, some trend detecting capabilities are sacrificed. This new network will continue to be monitored on a monthly basis. Specific station type and locations for the complete network are presented in Appendix 2. Station locations and water quality parameters monitored in WY 1991 are presented in Figure 1 and Table 1.

Core/Bench Mark Stations

Core/Bench mark stations are sampled monthly year after year and provide information for tracking changes in water quality over time (trends).

Locations of Core stations were based on the following criteria:

1) near the mouth of the major river basins that flow into the three major receiving waters of Washington State;

   a) Puget Sound,
   b) Columbia River, and
   c) Grays Harbor;

2) where major rivers enter Washington State; and

3) downstream of major impact areas.

Bench mark stations are established in the upper reaches of a few select river basins to track upstream/downstream changes.

Rotating Stations

Rotating stations are located at 1) the mouths of the remaining rivers that flow into Puget Sound; 2) on major tributaries to rivers with core stations; or 3) on rivers and streams with known water quality problems. These stations will be active once every three years. When active, a rotating station will be sampled monthly. Information from these stations will be used primarily to determine if the waters meet their designated uses, in support of Ecology's permit process and, to a lesser extent, to track water quality changes over time.

Floating Stations

Floating stations are established primarily to address short-term, site specific water quality concerns expressed within Ecology or by other clients, such as the Puget Sound Water Quality Authority (PSWQA). Floating stations are generally sampled monthly when active but the sampling duration is study specific and may or may not last for the complete wateryear. These

Total Hard = Total Hardness

stations allow the program to generate timely water quality information without disruption to its primary sampling network. These stations not only provide support for Ecology's permit process, but also allow Ecology to focus on areas of increasing concern.

Inside of Puget Sound Basin Monitoring Network vs. Ecology WY 1991 Network

In 1987, PSWQA concluded that "...there is currently no long-term comprehensive program to monitor Puget Sound and its resources..." and appointed a committee to design a Puget Sound Ambient Monitoring Program (PSAMP) (PSAMP, 1988). Ecology, in cooperation with PSWQA, modified a portion of its Freshwater Ambient Monitoring Program to better reflect the specific goals and objectives of PSAMP. For planning purposes, Ecology's statewide freshwater rivers and stream monitoring program was divided into two parts: 1) inside of the Puget Sound Basin (those stations that flow into Puget Sound); and 2) outside of the Puget Sound Basin (the rest of the state).

For WY 1991, the Ambient Monitoring Section collected water quality samples at 36 stations on rivers and streams that flow into Puget Sound (see Figure 1). These stations represent approximately 43% of Ecology's statewide freshwater ambient monitoring efforts. Ecology's new network design inside of the Puget Sound Basin is comparable to the design developed by PSAMP (Table 2). The major difference between the two plans is the addition of two bench mark stations in place of two floating stations in Ecology's new design. However, Ecology's program in WY 1991 reflected a transition, and the final rotating network will require additional fine tuning to reflect a basin wide perspective.

Table 2. Comparison of PSAMP Rivers and Stream Monitoring Network (PSWQA, 1988) and Ecology's WY 1991 Network.

Total Per Year	**35**	**36**

Sample Collection

Monthly samples are collected as part of four monitoring "runs": Eastern, Central, Northwest, and Southwest. The Eastern, Central, and the first two days of the Southwest Run cover all freshwater stations outside of the Puget Sound Basin and are typically completed the first, second, and fourth weeks of each month. The Puget Sound portion of Ecology's Freshwater Program is collected as part of the Northwest Run and the last day of the Southwest Run. The Northwest Run includes all monitoring stations north of the Puyallup River and is typically completed the third week of the month. The Southwest Run includes stations in South Puget Sound and Hood Canal and occurs during the fourth week of the month.

The majority of the water samples are collected as single grab samples from highway bridges near midchannel. At a few sample locations, where bridge sites have inadequate mixing or pose a potential hazard to monitoring staff, the sampling sites are accessed from the river bank. All water samples are collected from approximately six inches below the surface to minimize surface contamination. Water samples for all conventional parameters, except fecal coliform bacteria and total suspended solids (TSS), are collected in a stainless steel sampler similar to the dissolved oxygen (D.O.) and BOD sampler design presented on page 4-151 of the 17th Edition of Standard Methods (APHA-AWWA-WPCF, 1989). The TSS samples are collected directly in a separate sample bottle secured as a passenger to the D.O. sampler. Water samples for fecal coliform analysis are collected in a sterilized sample bottle in a flow orienting sampler. Whole water samples for metals analysis are collected directly in a specially cleaned and quality controlled sample bottle provided by Ecology's Manchester Laboratory. The sample container is placed in a flow orientating stainless steel sampler designed specifically to hold the sample bottle.

Concurrent with the collection of water samples, on site measurements are taken for barometric pressure, time of day, stage height for flow determination by USGS (if required), and *in-situ* temperature.

Water samples are analyzed for the following conventional parameters:

Specific Conductivity	Total Suspended Solids	pH
Nitrate+nitrite	Dissolved Oxygen	Turbidity
Dissolved Nitrite	Fecal Coliform Bacteria	Total Phosphorus
Ammonia	Dissolved Ortho-phosphorus	

At select stations the following additional parameters are included:

Total Hardness	Cadmium (Total Recoverable)
Lead (Total Recoverable)	Chromium (Total Recoverable)
Mercury (Total)	Copper (Total Recoverable)
Zinc (Total Recoverable)	

Field Processing

Most of the conventional parameters, except TSS, and fecal coliform, require additional processing in the field. The D.O. bottle is removed from the D.O. sampler and fixed with alkaline iodide-azide and manganous sulfate. Water remaining in the D.O. sampler is split out for 1) field analysis, 2) laboratory analyses requiring whole water, and 3) filtering in the field. Water samples for dissolved nitrite and dissolved ortho-phosphorus determination are filtered in the field through a 0.45 μm acetate filter. After processing, all samples for laboratory analysis are tagged, buried in ice, and shipped to arrive at Ecology's Manchester Laboratory within 30 hours from the time of collection.

Field Analysis

Conductivity and pH are typically measured within 10 minutes of collection of the water sample. Dissolved oxygen samples are fixed in the field, as previously described, for subsequent Winkler titration upon completion of the sampling run (within three days of collection).

Laboratory Analysis

For specific information on method of analysis, detection limits, holding time, and other important information for each of the above parameters, see Appendix 3.

Data Handling

Data collected as part of this program are entered into two independent computer systems and follows the flow diagram presented in Figure 2. Monitoring staff enter field observations and data directly into the Ambient Monitoring Section Database (AMSD). Laboratory data, after bench and senior level review, are entered into the laboratory computer system and later downloaded via modem to AMSD. As part of this transfer, laboratory data are passed through a two step quality assurance (QA) check. Data are accepted, qualified, or rejected (see QA Section). The data are 100% verified for transcription errors and finalized. Ecology's finalized data sets are uploaded to EPA's STORET database, and to PCSTORET (a Micro-computer version of STORET) quarterly. Data transfer will expand to include PSAMP central database when the freshwater portion becomes available.

Quality Assurance

Quality assurance practices (QA) in the Freshwater Ambient Monitoring Program are incorporated in each of the three major components of the program: 1) field, 2) laboratory, and 3) data.

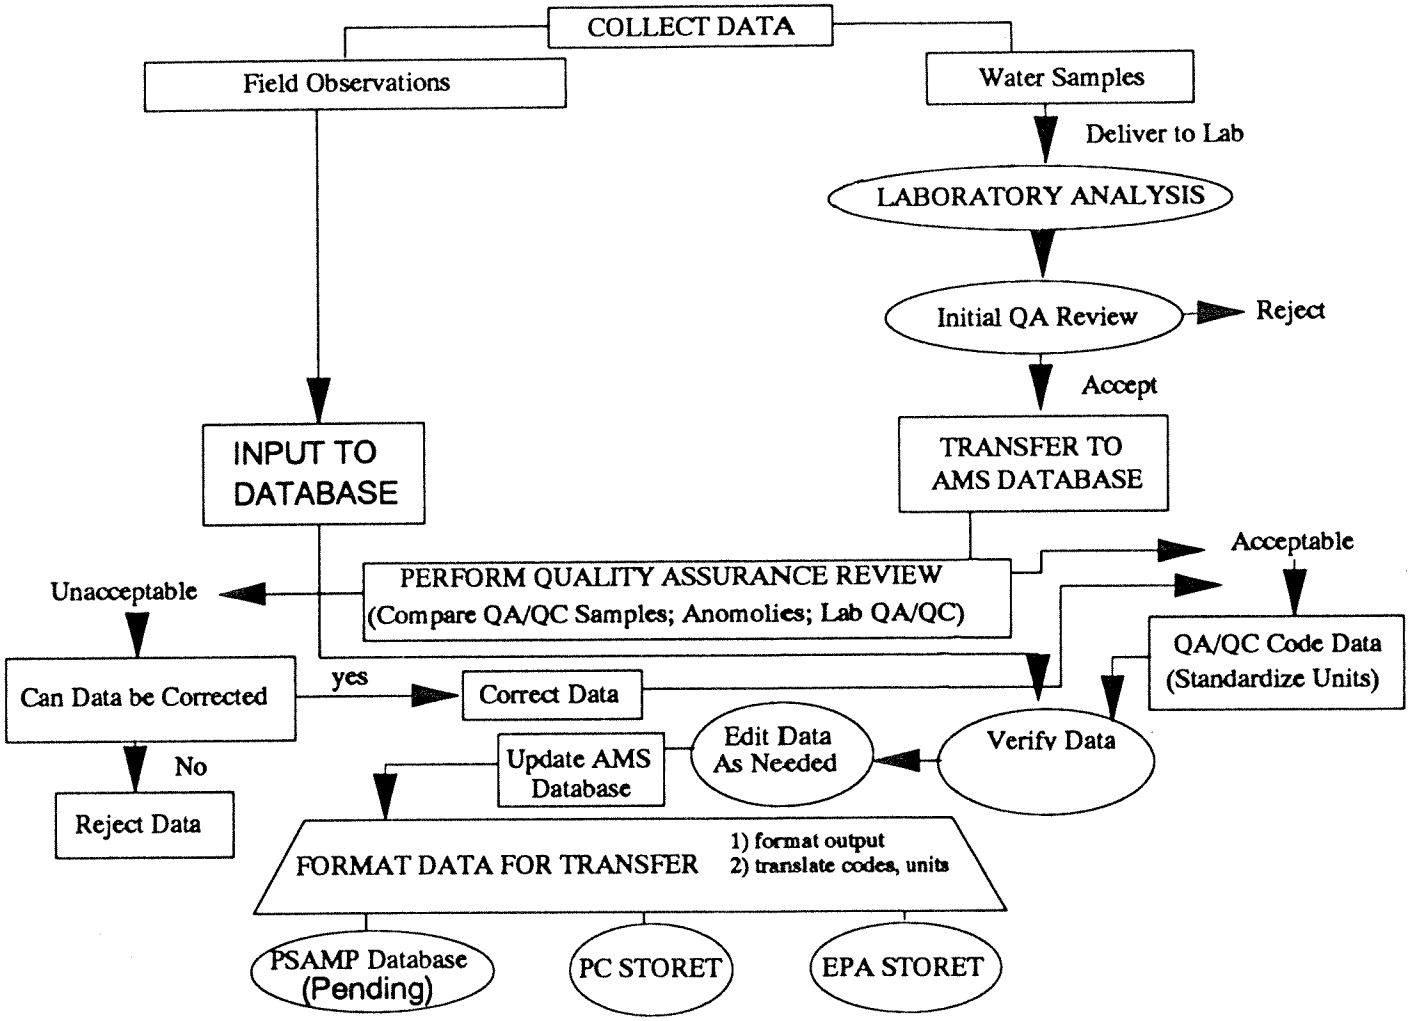

Figure 2. Date flow diagram for Ecology's Ambient Monitoring Section's River and Stream Monitoring Program.

Field QA

The QA practices for field operations consist of three parts: 1) adherence to a standard operating procedure manual and annual performance evaluation of sampling personnel; 2) instrument calibration schedules; and 3) collection of an additional water sample, at random, each day of the run for the purpose of Quality Control (QC). The first two parts help minimize variability from multiple samplers and field instruments. Analysis of field replicates, blanks, and splits are used in conjunction with laboratory QC to ascertain overall data quality.

Laboratory QA

The laboratory conducts a comprehensive QA program to ensure that analytical data meet project requirements for accuracy. The QA program includes the use of control charts for some QC results and the QC procedures specified in the analytical methods (Ecology, 1991).

Data QA

Data from the Freshwater Ambient Monitoring Program are subjected to two levels of verification before entry into the final database. "Level one" runs the data through a series of checks ranging from holding time to comparing variability between field duplicate results, and assigns a quality code to each datum. The "level two" QA check consists of a manual review of data failing "level one" and re-coding the quality code from 1-9, 1 = the data meets all QA requirements and 9 = the data are unusable.

Data Analysis

All graphic presentations and data analysis performed on Ecology's ambient freshwater data were completed using a water quality/hydrological graphic/analysis system developed by Eric Aroner (WQHYDRO) (Aroner, 1992).

Trends

Seasonal Kendall Trends determinations (Hirsch *et al.*, 1982) were completed for most of the major water quality constituents on core/bench mark stations located inside of the Puget Sound Basin. Data were checked for autocorrelation and for correlation to stream flow. Autocorrelation, if present, indicated that part of the information from one sample may be present in the preceding sample, therefore, the measurements were not truly independent. Correlation to stream flow indicates concentrations are in some way related to flow. This relationship with flow introduces variability (noise) into the data set that reduces the ability to detect trends. However, if the purpose of the study, as in our case, is to address in-stream concentrations as they relate to potential uses rather than address the cause of the trend, then removal of variability due to flow may not be desirable (Hirsch *et al.*, 1991). Correction for serial correlation (autocorrelation), was conducted on data that expressed probability of > 80%

for serial correlation. When serial correlation was present, SK tests with correction for serial correlation (SKWC) were used in place of SK tests for trend determination. Seasonal Kendall tests were flow adjusted if the data showed a regression with $R^2 > .10$ for flow versus concentration. Table 3 lists the regression and the corresponding formulas used to evaluate the relationship between flow and concentration.

If the median of the given data set was above the working quantitation limit for the parameter (data fall within the working range of the test) and the trend had a probability of > 95%, then percent change per year was calculated (slope/mean x 100) and the corresponding trend graphs are included in this report. The working quantitation limit is defined as twice the pooled standard deviations of replicate pairs near the laboratory detection limit. If the median was below the working quantitation limit, apparent trends may be an artifact of changing detection limits, so percent change per year was not calculated and the trend information should be used with care.

Upstream/Downstream Comparison

For upstream and downstream comparison between bench mark and core stations inside of the Puget Sound Basin, the following non-parametric tests were used; Klotz, Anderson-Darling, and the Wilcoxon-Mann-Whitney Rank Sum Test (non-parametric alternative to t-test). The Klotz Test of equality of variances/spread was the first statistical test completed (for more information see Aroner, 1992). Significant results (>80% probability) of the Klotz Test indicate the data sets do not have equal variance and further statistical comparisons should use the Anderson-Darling Test. Non-significant results of the Klotz Test indicate the data sets are similar in distribution and the assumptions of the Wilcoxon Rank Sum Test are met. The Anderson-Darling Test (Scholtz and Stephens, 1987) is a non-parametric test for differences between distributions which compares central tendencies and variance/spread (together and separately). The Anderson-Darling Test is not limited by the requirement that populations have equivalent distributions. The Wilcoxon-Mann-Whitney Ranked Sum Test (Marascuilo and McSweeney, 1977) compares the difference between means of the two populations to see if they are statistically different.

GENERAL RESULTS AND DISCUSSION

Raw data and six-year summary statistics for WY 1991 are presented by station in Appendix 4. All Water quality data for WY 1991, and six-year summary statistics, are presented by station in Appendix 4.

Ecology's ambient monitoring data are part of the public record, and are widely distributed. In a typical year, over 100 data requests are received from consulting firms, local and state agencies, schools, and private individuals. Within Ecology, the data are used to support wasteload allocation models, preparation of the 305(b) and other management reports, and

13	L/L/Cubic	{Y =EXP(a+b*LnX+b1*SQR(LnX)+b2*CUBE(LnX))}

For more information see water quality/hydrological graphic/analysis system (WQHYDRO) (Aroner, 1992).

provide environmental quality information necessary for Centennial Clean Water Fund and other grant awards. The Puget Sound Water Quality Authority also uses these data to address the current status of rivers and streams that flow into Puget Sound in their annual Puget Sound Update Report.

The following discussion is divided into four areas: 1) QA review; 2) general water quality for WY 1991; 3) water quality at core/bench mark stations inside of Puget Sound Basin; and 4) water quality at floating stations.

QA Review

The results of field replicate pairs provide an estimate of total variability (instream+field processing+laboratory). Appendix 5 summarizes the raw field QC data for the replicate pair samples collected in WY 1991. The goal of our program is to have 90% of the replicate pair data fall within the assigned range of percent of coefficient of variation (%CV=SD/$\bar{x}$ x 100). The acceptable ranges for specific parameters, and the corresponding percent of the statewide WY 1991 replicate data that were within the range, are shown below:

Difference between 20% CV	10% CV	Replicates + 0.1 unit
Conductivity - 98%	Ammonia - 77%	pH - 70%
Fecal Coliform Bacteria - 49%	Nitrate+nitrite - 97%	D.O. - 90%
Suspended solids - 64%	Dissolved Nitrite - 94%	Temperature - 92%
Turbidity - 88%	Total Phosphorus - 90%	
	Ortho-Phosphorus - 93%	

At low level concentrations, near detection limits, relatively small differences can result in high %CV values. For example, fecal coliform counts of one and two on replicate samples would result in a %CV of >47%, when in reality this difference is indistinguishable (Nancy Jenson, personal communication, 1992).

A significant portion of the fecal coliform, suspended solids, and ammonia data pairs used to calculate %CV were below the working quantitation limits of the test (44% ,34%, and 61%, respectively). Even after replicate pairs near detection limits were removed, and the percent CV recalculated, 31% of the fecal coliform and 26% of the suspended solids still fell outside the desired ranges. Both of these parameters are, however, typically patchy in nature and high total variability can be expected.

Replicate pairs for pH, D.O., and temperature were compared against a $\pm$ 0.1 standard unit range (instead of %CV) for ease of in field tracking (this allows problems with methods and equipment to be corrected as they became apparent). Temperature and D.O. pairs were acceptable (Appendix 5); however, > 30% of pH replicate pairs exceeded the $\pm$ 0.1 criteria range (Appendix 5).

The remaining element of the QA program, laboratory variability was assessed by laboratory staff via manual review of laboratory quality control charts, check standards, in-house matrix spikes, and laboratory blanks (Ecology, 1991). Laboratory variability fell within acceptable ranges and did not appear to present any problems for WY 1991 analyses.

It should be noted that the above described QA information pertains to WY 1991 data only and similar information is not available for previous years.

Overview of Water Quality for Wateryear 1991

The discussion of general water quality for WY 1991 is divided into three areas: 1) statewide, 2) inside of the Puget Sound Drainage Basin and, 3) outside of the Puget Sound Basin. Select water quality parameters in each of these areas are presented graphically as box plots. These plots also display Class "A" water quality standards for those parameters where standards are established (the criteria line for fecal coliform bacteria is included even though the water quality standards permit up to 10% of the samples to exceed 200 organisms per 100 mL and comparisons to standards should be based on more than one sample). Figure 3 shows how to interpret the box plots.

Statewide Water Quality

On a statewide basis, Washington's rivers and streams exhibit a wide range of water quality (see Figure 4; Table 4). Fecal coliform violations occurred in every month of the year, and was the most frequently violated water quality standard in Washington in WY 1991. Temperature, being seasonal in nature, had a higher percentage of violations in August 1991. Dissolved oxygen violations were infrequent in WY 1991.

Water Quality in the Puget Sound Drainage Basin

In general, the water quality of rivers and streams that flow into Puget Sound is relatively good with occasional violations of Class "A" standards for fecal coliform; to a lesser extent for temperature; and infrequently for D.O. and pH (see Figure 5). Of course, individual stations may have violated these standards at a different frequency than was indicated by the Puget Sound summary. Thirty-eight percent of the 34 stations inside of Puget Sound were in violation of state water quality standards for fecal coliform at least one time during WY 1991. More important, five locations: the Sumas River, Sammamish River, Puyallup River, White River, and Chambers Creek comprised over 63% of the total fecal coliform bacteria violations recorded in WY 1991 (Table 4). Temperature violations occurred at 32% of the stations, but at a frequency no higher than twice for any one station. Dissolved oxygen violations were found at four stations during WY 1991, but a review of the raw data for percent saturation indicate the

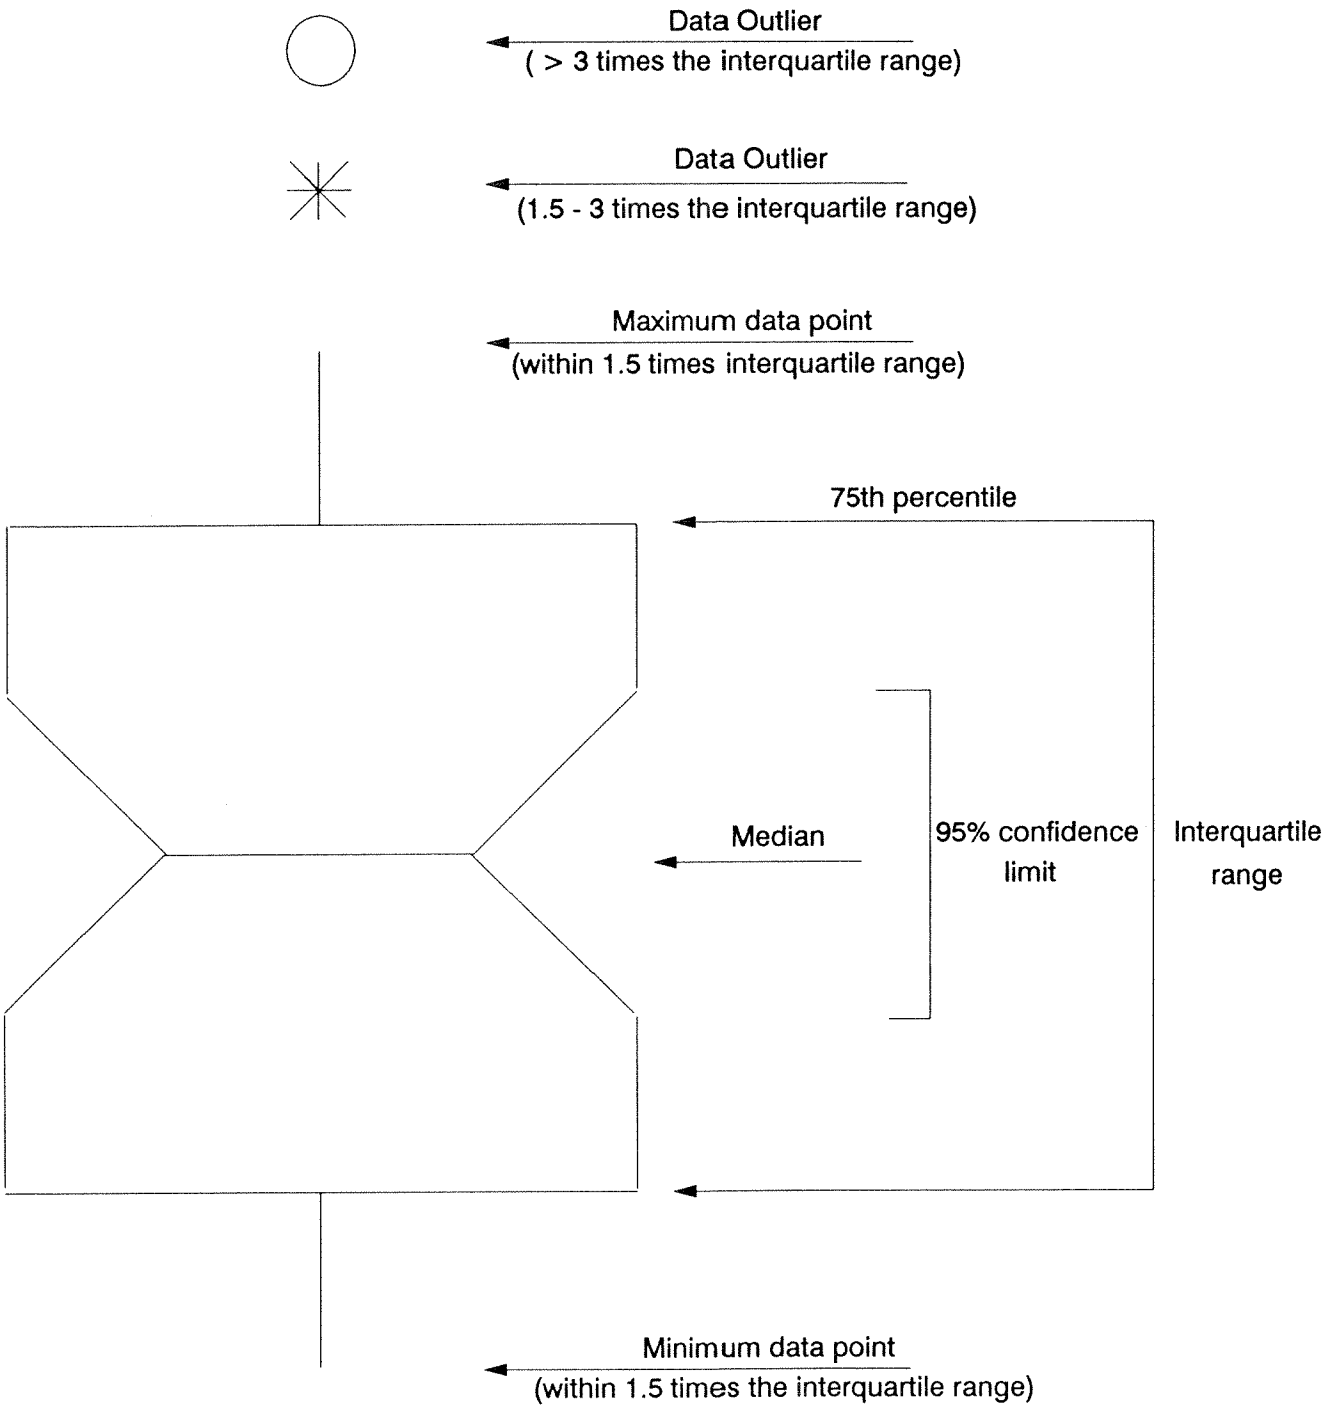

Figure 3. How to interpret a box plot (modeled after figure in Coots, 1991).

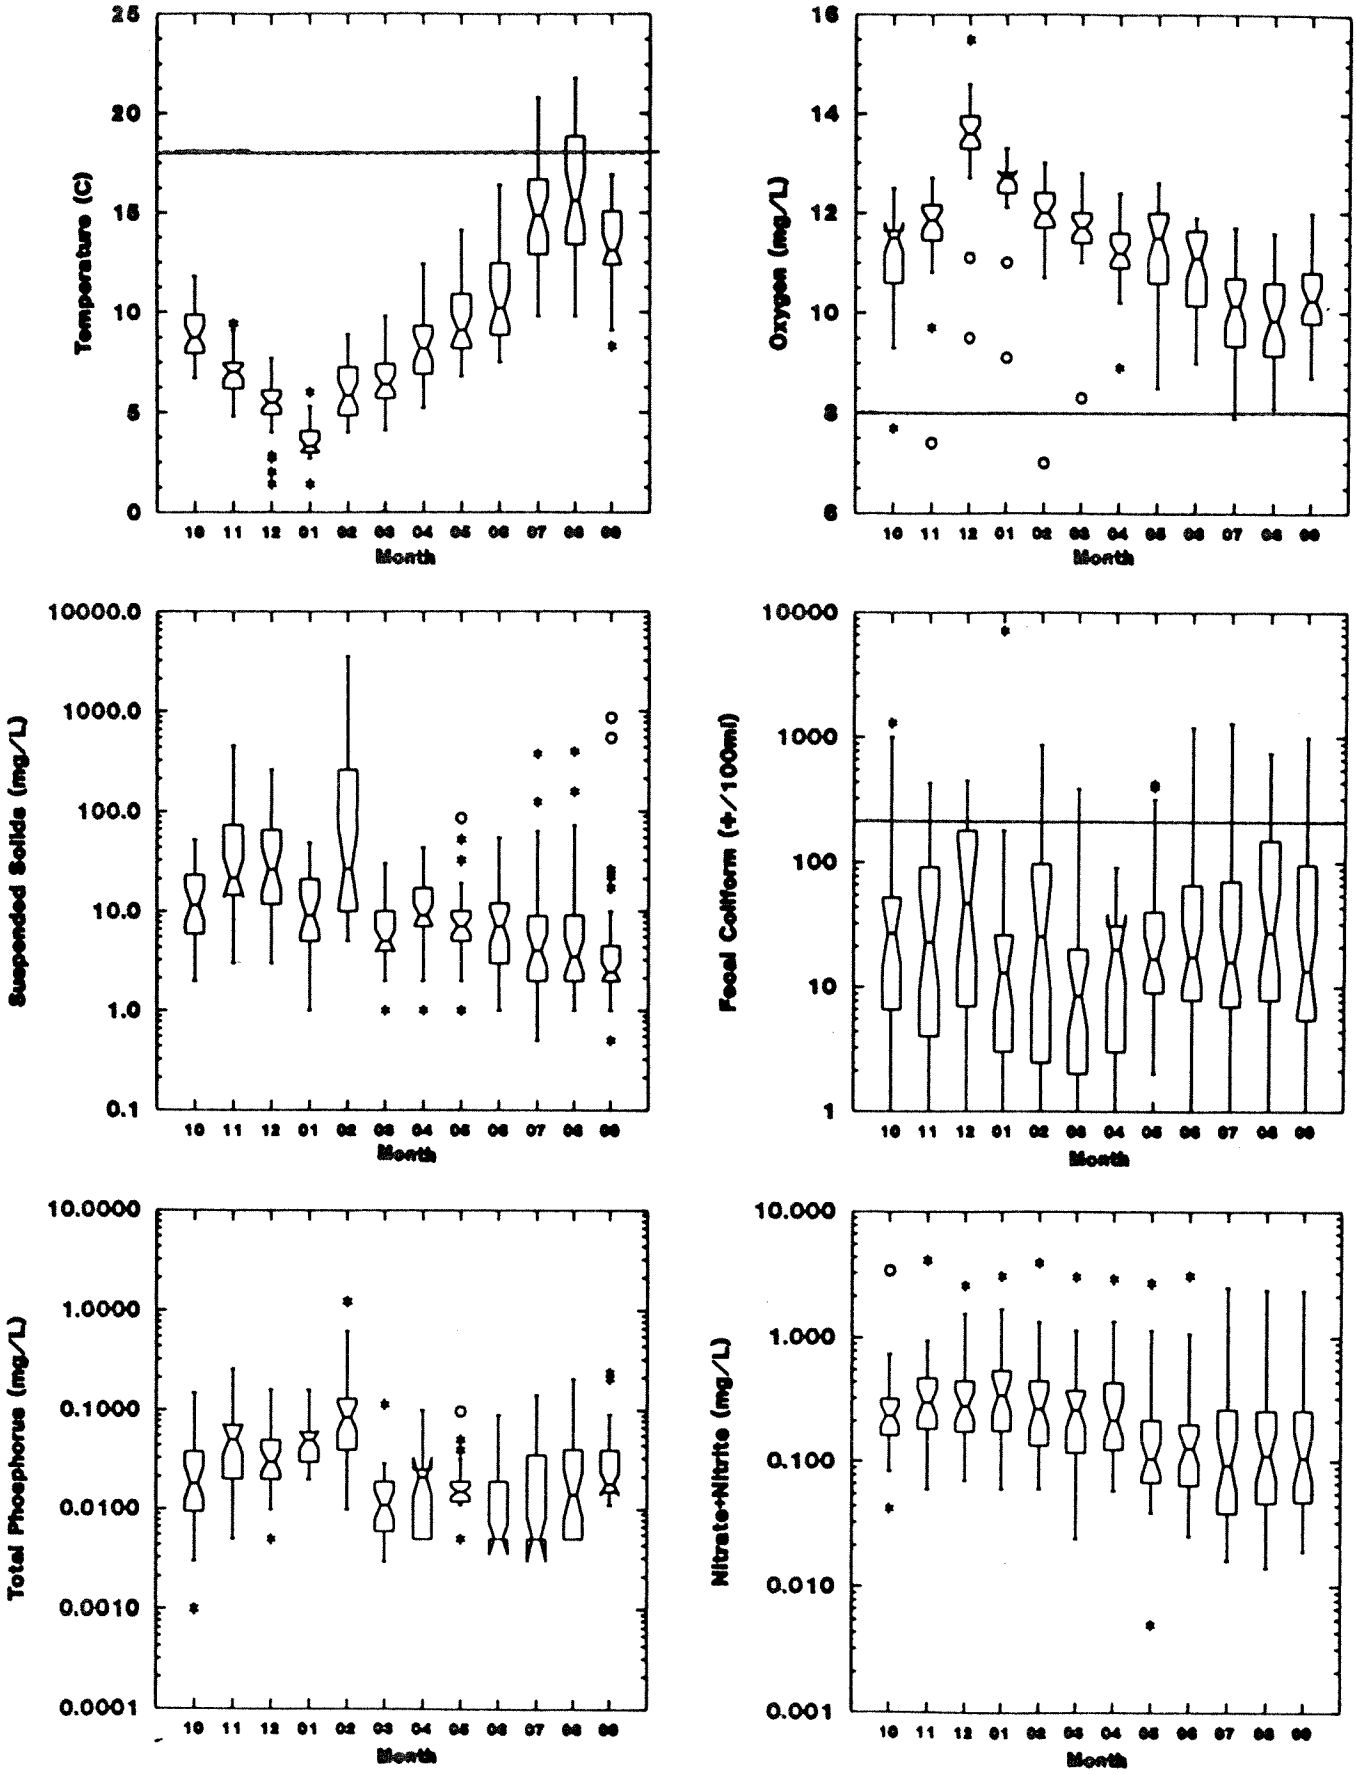

Figure 5. Inside of Puget Sound Basin temperature, dissolved oxygen, total suspended solids, fecal coliform, total phosphorus, and nitrate+nitrite levels for Wateryear 1991. (Class "A" Washington State Water Quality Standards, if established, included as a solid line.)

Sumas River may be the only site that may truly express a D.O. problem. Violations for pH occurred during WY 1991 at the same frequency as for D.O. However, as discussed, pH values have a large potential for measurement error and should be used with care (Appendix 5). See "Water Quality at Core/Bench Mark Stations Inside of the Puget Sound Basin" for station-specific discussions of water quality.

Water Quality in Washington Outside the Puget Sound Basin

Washington State excluding the Puget Sound Basin is broken into two distinct areas: 1) east side - stations located east of the Cascade mountains; and 2) west side - stations located west of the Cascade Mountains and not in the Puget Sound drainage basin.

Water Quality East of the Cascades

Water quality for the east side of Washington State for WY 1991 was generally good with only occasional and somewhat seasonal water quality violations (Figure 6). The most significant of these violations involved temperature and fecal coliform bacteria levels. In August and September 1991, half of the instream water temperatures did not meet Class "A" water quality standards. As for fecal coliform bacteria, 34% of the stations violated state standards at least once during WY 1991, but three stations (the S.F. Palouse River at Pullman, Tucannon River at Powers, and Little Spokane River near Griffith Springs) comprised over 60% of the total violations. Table 4 lists stations and the number of water quality violations in WY 1991 for temperature, D.O., pH, and fecal coliform bacteria.

Water Quality West of the Cascades (Excluding Puget Sound Basin)

Water quality for west side stations was similar to that found statewide. That is, generally good with occasional violations of water quality standards. The majority of these water quality violations involved elevated fecal coliform bacteria concentrations and temperature. Table 4 lists stations and the number of water quality violations in WY 1991 for temperature, D.O., pH, and fecal coliform bacteria. The majority of water quality violations (48%) were measured on two rivers: the Black River near Moon Road Bridge, and the Chehalis River at Centralia. The most significant of these violations is the high number of D.O. violations on the Black River near Moon Road Bridge. The raw data and summary statistics present in Appendix 4 show that the Black River has a chronic D.O. problem expressed by the low maximum percent saturation for WY 1991 of 81.3%.

Water Quality at Floating Stations

At the request of Ecology's Northwest and Eastern Regional Office, the Freshwater Ambient Monitoring Program collected water quality information at three locations on the upper Snoqualmie River and at five locations on the Little Spokane River system in WY 1991. The purpose of these studies were to generate water quality information to be used to support regional activities. For more specific information, see Appendix 6.

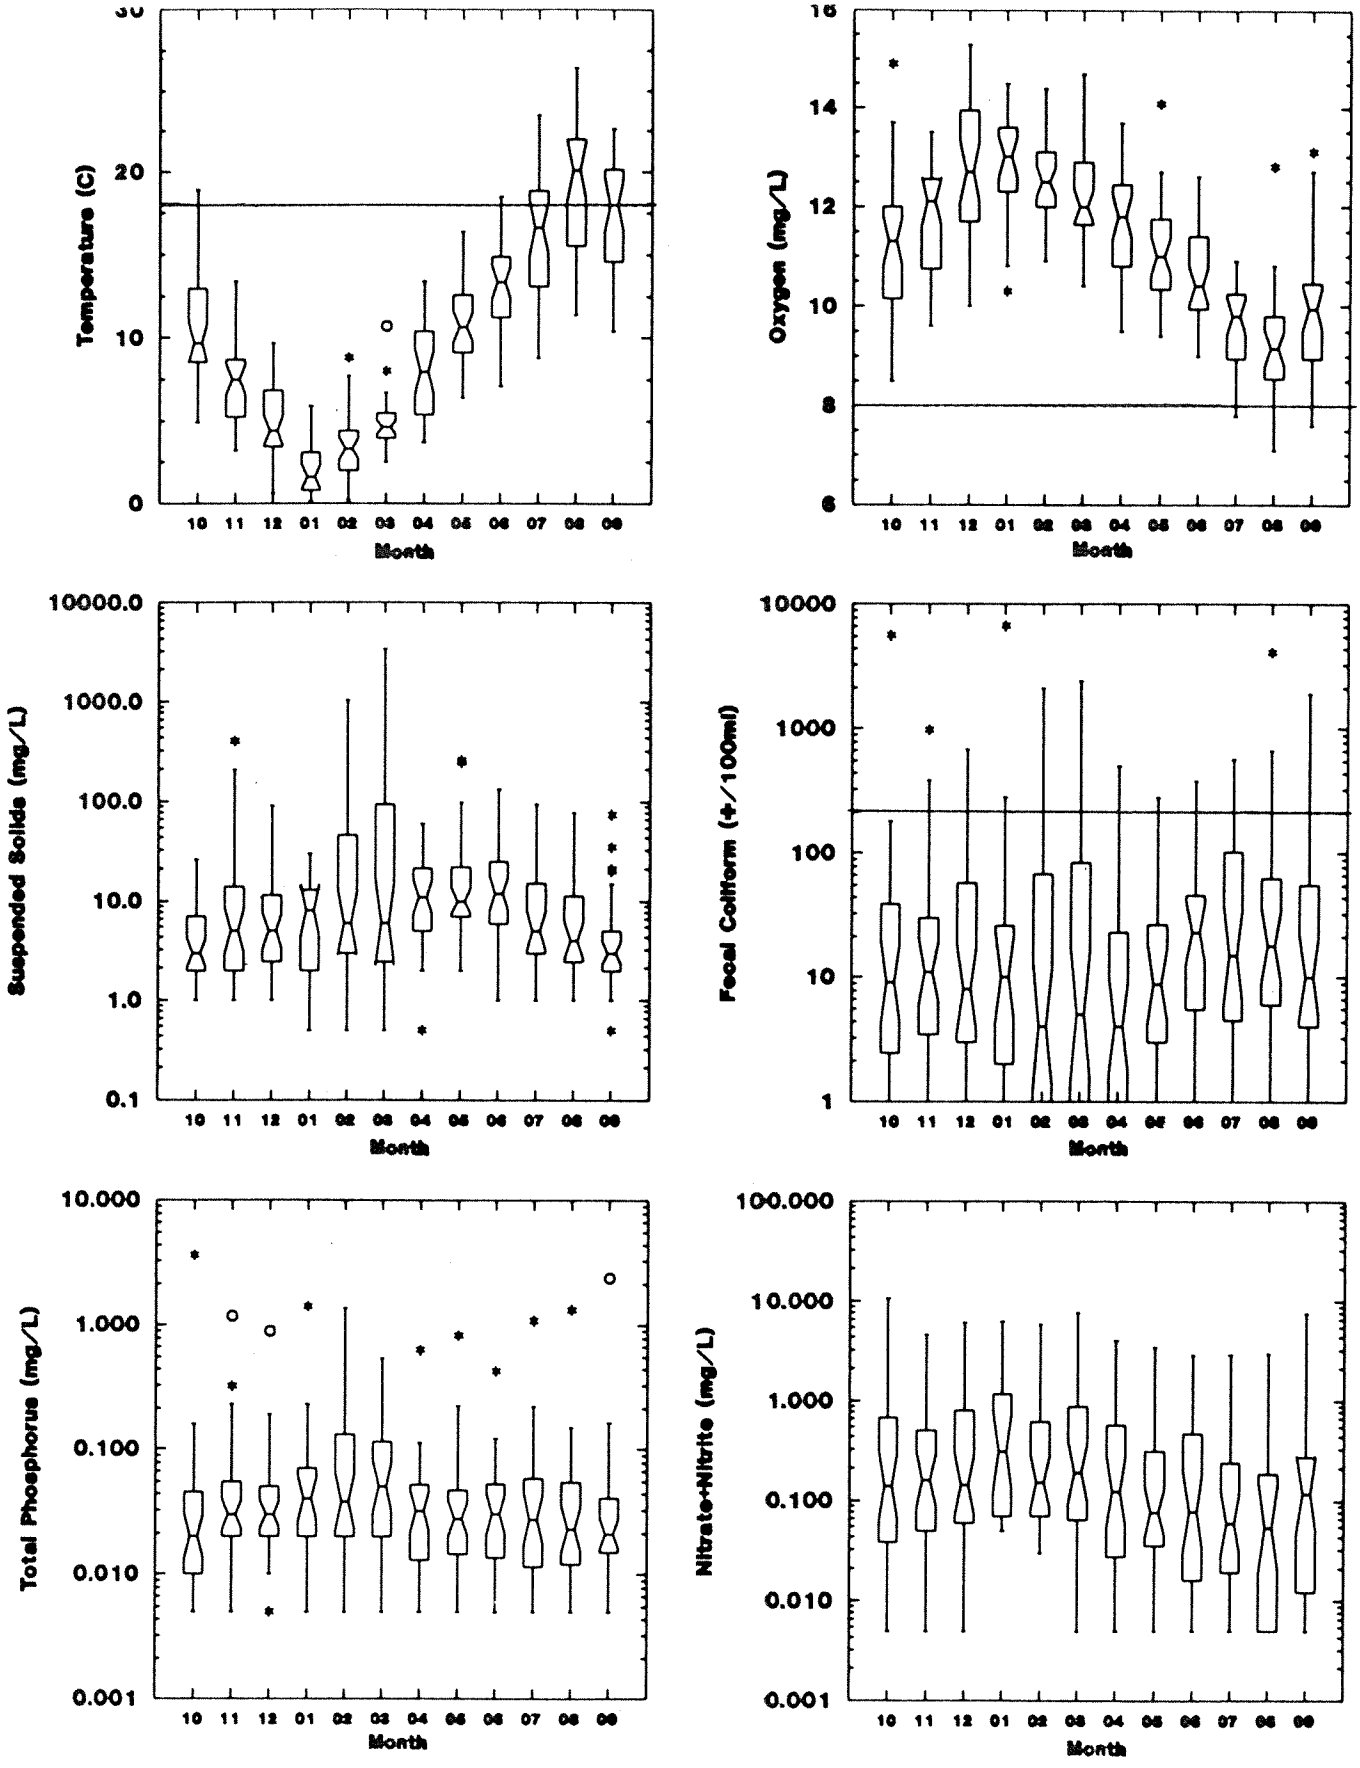

Figure 6. East of the Cascades temperature, dissolved oxygen, total suspended solids, fecal coliform, total phosphorus, and nitrate+nitrite levels for Wateryear 1991. (Class "A" Washington State Water Quality Standards, if established, included as a solid line.)

PART II:

Water Quality Summary and 12-Year Trends for Core Stations in the Puget Sound Basin

INTRODUCTION

In Part II of this report, the 10 core stations and 2 bench mark stations located in the Puget Sound Basin are addressed individually to a) compare WY 1991 data to the last 10 years of data (October 1982 to September 1991), b) examine trends over the 12-year period from October 1979 through September 1991, and c) to discuss general water quality conditions at each station. Individual station accounts of the 12 Puget Sound core/bench mark stations that were analyzed begin on page 27. For a program description and discussion of field, laboratory, and analytical methods, see Part I of this report.

Ranking of Puget Sound Core Stations

The 10 Puget Sound core stations were ranked, by parameter, according to the mean of the highest quarterly concentrations recorded at the stations over each of the last six years (Appendix 7). Appendix 7 provides only a simple ranking of means and does not address the variance around the mean nor does it indicate the significance of the differences between means.

Summary of Trends at Core/Bench Mark Stations Inside of the Puget Sound Basin

Appendix 8 presents a summary of the trends at core/bench mark stations in the Puget Sound Basin. Turbidity and conductivity levels inside the Puget Sound Basin appeared to be the only parameters showing a general basin wide trend with 6 of the 12 stations showing declining trends. Ammonia levels also appeared to be decreasing at 5 of the 12 core/bench mark stations, but these trends should be viewed cautiously (see below). Fecal coliform bacteria levels appeared to decline at one third of the stations; however, it was still the most frequently violated Water Quality Standard in WY 1991. The remaining parameters did not exhibit overall trends pointing in any one direction.

Limitations of Trend Analysis on Core/Bench Mark Stations Inside of the Puget Sound Basin

One area that may be confusing to the reader is when the Seasonal Kendall Trend Test (see page __) indicates a significant trend in the data set but the trend has a slope of 0.0000. The SK Trend Test and the slope of the trend are calculated independently. Therefore, a significant trend may be present in the data set but the rate of change is below the ability of the slope calculations to detect. Most of these significant trends with 0.0000 slope were calculated using data sets where the historical median levels are below the working quantitation limit. These data sets contain many data points at or near detection limits which consistently includes a high number of equal values ("ties"). This limitation of the slope calculation can, and occasionally does, also occur on data sets well within the working range of the specific parameter. An example is the pH data for the Puyallup River, where a significant trend was present with a slope of 0.0000. The direction of the trend is indicated by the ↑ or ↓ following the slope and is determined from the Seasonal Kendall Z statistic.

Another issue worth noting is that trend work performed on low level results, especially nutrient and turbidity data, should be used with caution. Laboratory or procedural changes have occurred during the last 10 years that may be reflected in the data set (Dave Hallock personal communication, 1992). These changes may manifest themselves in false or misleading trends, especially when the data are near the reported detection limits. The comparison between the working quantitation and the historical median is one attempt to minimize the reporting of these misleading trends. However, this comparison alone may not eliminate all questionable trends for nutrients. For example, the trend graphs for ammonia for 4 different stations (Sammamish River at Bothell, Cedar River at Renton, Puyallup River at Meridian Bridge, and Nisqually River at Nisqually) look surprisingly similar.

The most significant question to address when discussing trend analyses on core/bench mark stations in the Puget Sound Basin is "Do these trends reflect true in-stream changes or do they merely reflect procedural changes within the program (introduced bias)?" Potential sources that may have introduced bias into the data include, but are not limited to, changes in 1) sampling and/or analytical methods, 2) laboratories performing the analyses, 3) detection limits, 4) time of collection, and 5) sampling personnel. Unfortunately, historical QA procedures have not always been as rigorous as they are currently, and the absence of this information limits the evaluations of data quality and makes it difficult to address how greatly any parameter may have been affected by program changes. This should be kept in mind when interpreting all trend results presented within this report.

INDIVIDUAL STATION ACCOUNTS

NOOKSACK RIVER AT BRENNAN

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data for most of the conventional parameters in Figures 7, 8, and 9. Temperature appeared to be the only parameter to be seasonally above average with half of the measurements in WY 1991 above the 75th percentile line. However, temperature levels during the critical months of August and September were still below "Class A" water quality standards of 18°C. Dissolved oxygen for the most part reflected the expected inverse relation to temperature with five of the twelve measurements at or below the 25th percentile line. The remaining parameters, with the exception of total phosphorus, were generally within historical levels. Total phosphorous levels for November, December, and February were at (or established) new 10-year maximums.

Trends in Conventional Water Quality (10/79 - 09/91)

Seasonal Kendall (SK) Trend information is provided in Table 5. Significant trends were detected for conductivity, pH, and turbidity all at the 99% probability levels. The pH data showed a significant amount of serial correlation and the corresponding SK Trend with Serial Correction was not significant. Both conductivity and turbidity showed a significant correlation to stream flow. Flow adjusted SK Trend (FASK) for conductivity is increasing by $< 1\%$ per year, while FASK trends for turbidity are decreasing at $< 2\%$ per year (see Figure 10).

Overall Water Quality

The primary concern at this location is the persistent problem of elevated fecal coliform levels. This station had a three-month mean for fecal coliform levels (352 organisms per 100 mL) that ranked fourth among freshwater core stations inside of the Puget Sound Basin (Appendix 7). Fecal coliform levels for WY 1991 had 17% of the samples collected violate water quality standards. The highest three month mean value over the last six years occurred during summer low flow conditions. However, low correlation between flow and fecal coliform levels ($R^2=0.0928$) did not point to a consistent source. The Nooksack Station also ranked in the top three core stations for suspended solids, ammonia, nitrate+nitrite, total phosphorus, turbidity, and conductivity. Part of the problem, specifically suspended solids and turbidity, can be attributed to the nature of the river which is largely impacted by glacial till. However, this station still appears to have an elevated level of nutrients.

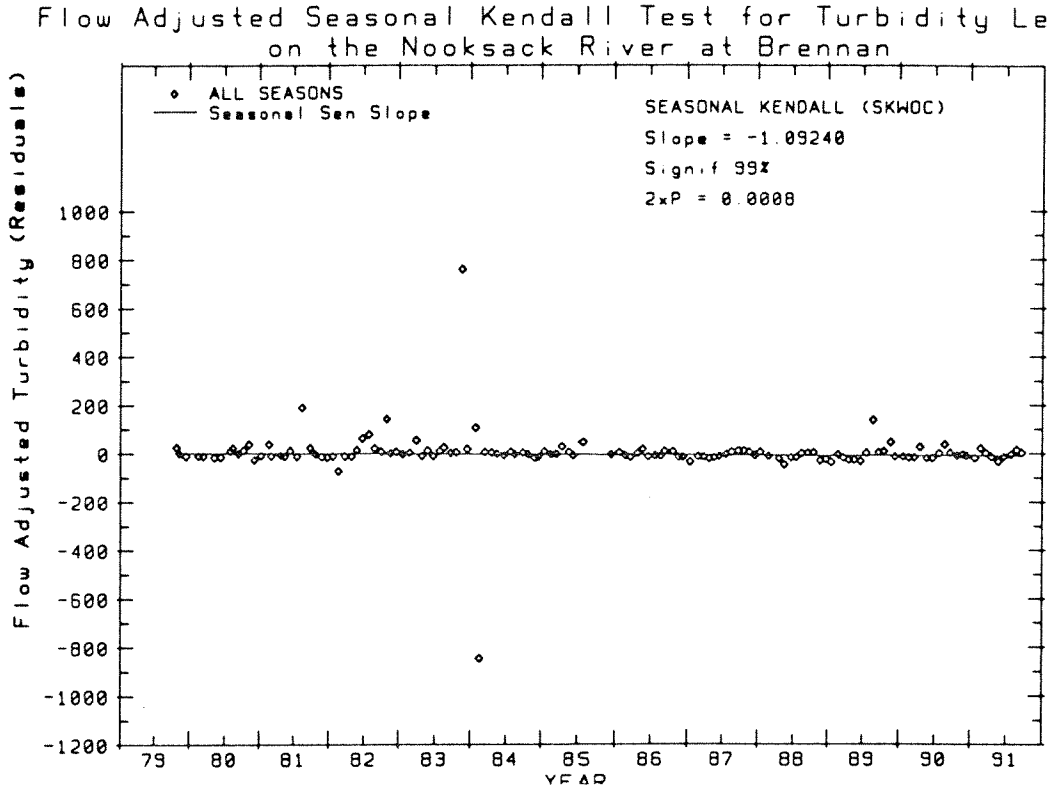

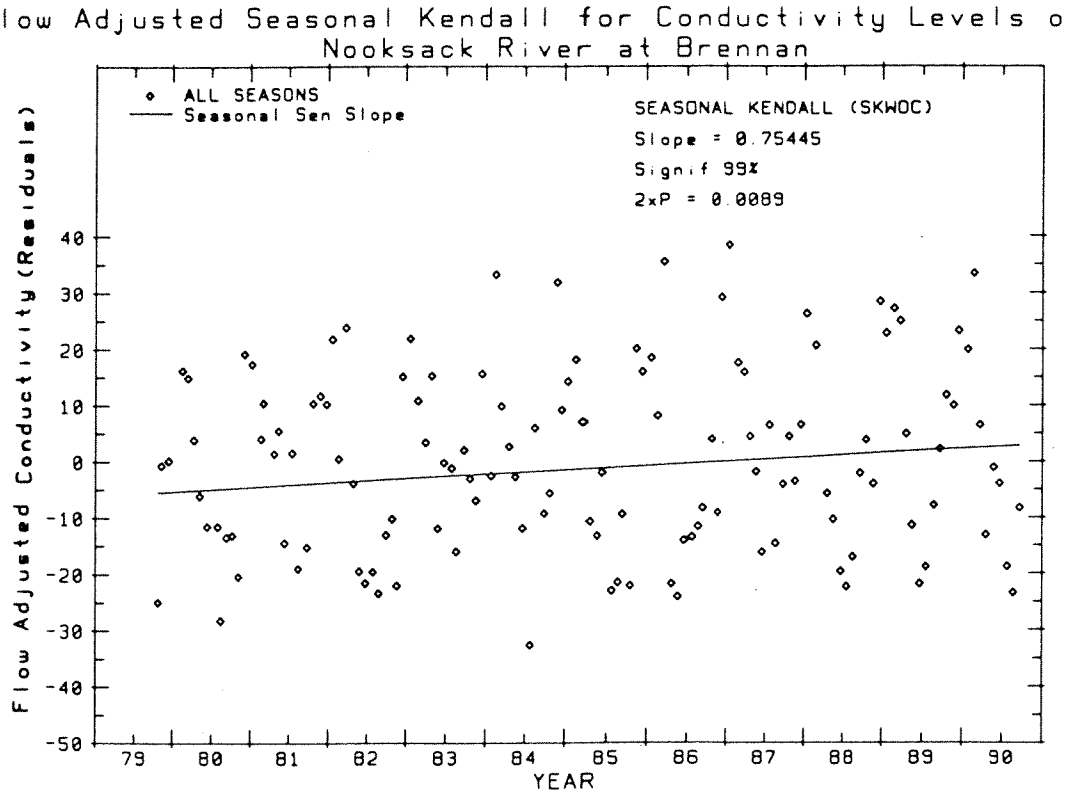

Figure 10. Significant trend graphs for the Nooksack River at Brennan.

SKAGIT RIVER AT MOUNT VERNON

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data for most of the conventional parameters in Figures 11, 12, and 13. Temperature, flow, suspended solids, and turbidity were all generally above historical median levels. Flow was especially high during the months of December, February, and July with each month reaching a new 10-year maximum level. Dissolved oxygen, pH, and nitrate+nitrite levels were below historical median levels. Dissolved oxygen levels reached new 10-year minimums for the months of March, April, and June and were below the 10-year historical median line 75% of the time in WY 1991. Conductivity and fecal coliform levels were scattered with both parameters setting seasonal maxima and minima.

Trends in Conventional Water Quality (10/79 - 09/91)

Seasonal Kendall Trend information is provided in Table 6. Significant trends were detected for turbidity, ammonia, and nitrate+nitrite, all at the 99% probability levels. Turbidity (FASK) expressed a decreasing trend with a 7.42% change per year (see Figure 14). Nitrate+nitrite and ammonia also exhibited a declining trend, but the median values of the data are below the working quantitation limit of the test.

Overall Water Quality

The Skagit River Station appears to have some of the best water quality of the core stations inside of Puget Sound. This station has not violated any water quality standards over the last 10 years.

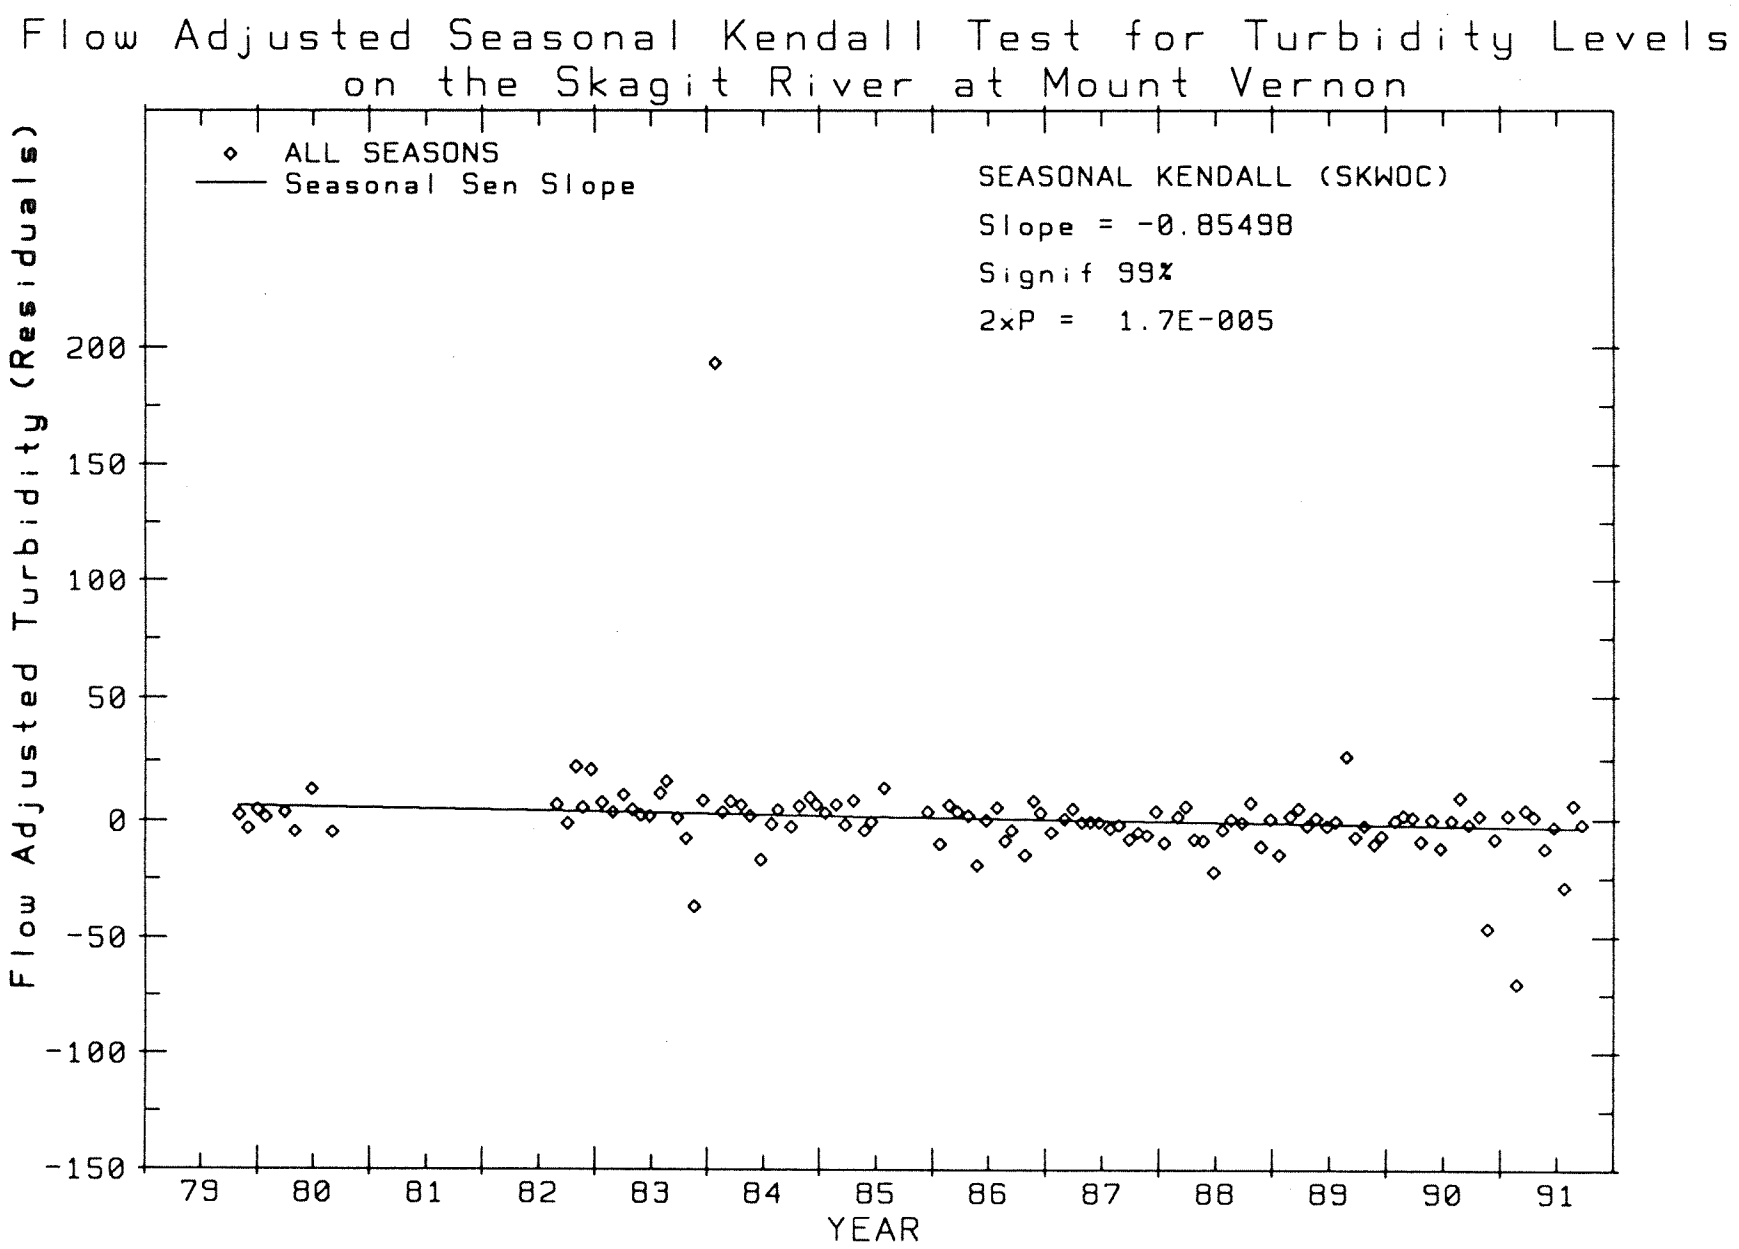

Figure 14. Significant trend graphs for the Skagit River at Mount Vernon.

SKAGIT RIVER AT MARBLEMOUNT

Wateryear 1991

This station is one of two bench mark stations operated within the Puget Sound. Wateryear 1991 data are compared to the last 10 years of data for most of the conventional parameters in Figures 15, 16, and 17. Most parameters were generally within the historical range. Flow and conductivity were the only parameters above historic median levels. Each parameter set three new 10-year maximum levels. Nitrate+nitrite levels in WY 1991 were low with 11 of the 12 measurements below historical median levels. March, August, and October all set new 10-year minimum levels for nitrate+nitrite.

Trends in Conventional Water Quality (10/79 - 09/91)

Significant decreasing trends were detected for temperature, ammonia, total and ortho-phosphorus, and nitrate+nitrite; all, except temperature, at the 99% probability levels (see Table 7). Temperature shows a declining trend, however, the data shows a large degree of serial correlation and corresponding SK with correction that did not indicate a significant trend. The remaining trends, though significant, are below the working quantitation limit of the specific parameters. It should be noted here that a significant portion of the indicated trend may be driven by changes in detection limits and should be used with care.

Overall Water Quality

For the most part, this station has exceptional water quality with the median of most conventional parameters falling below the working quantitation limit (see Table 7, column 12; and Appendix 5)

Upstream/Downstream Comparison

Table 8 presents results of the statistical analysis of paired upstream/downstream results from WY 1980 to WY 1991. The individual data pairs for each parameter are presented graphically in Appendix 9. The Klotz Test indicates conductivity and ammonia are the only parameters with similar distributions (shapes) for both upstream and downstream data sets. The subsequent Paired Wilcoxon-Mann-Whitney Test on these two parameters shows the means of the two data sets for both parameters are statistically different at the 95% confidence levels. The mean conductivity at Mount Vernon of the paired data was 3 μmhos higher than the mean calculated at Marblemount. As for ammonia, it also appeared to be statistically different, however, the difference of $\Delta = 0.00$ indicates there may be a problem with this statistical test when applied to data sets with a significant number of data points at or near detection limits.

Klotz - Nonparametric test of equality of variances/spread (populations of equal shape. significant results indicate data set do not have equal variance and A-D should be used.

Paired Wilcoxon - Nonparametric test for difference between means (assumes populations of equal shape). Significant test indicated the mean are different.

Anderson-Darling - Nonparametric test for difference between distributions (does not assume populations of equal shape).

L & S/R - Compares Central tendencies and spread/variance between stations.

S/R only - Tests scale and range (spread/variance) only by normalizing the data by subtracting the median (removes central tendencies) and retesting the new data set. Compares spread/variance only.

MV - Mount Vernon

M - Marblemount

The remaining parameters all had populations that had different distributions as indicated by significant Klotz in Table 8 and were tested using the Anderson-Darling Test. The only parameter that did not show a statistical difference between distributions at the 90% confidence level was pH. Dissolved oxygen and corresponding percent saturation did express a statistical difference in distribution, but when the data sets where corrected for central tendency and retested (A-D S/R only in Table 8), the data sets were not statistically different at the 90% confidence level. In other words, while the central tendency were statistically different, there was no difference in distribution. The remaining parameters: temperature, suspended solids, total and ortho-phosphorus, turbidity, fecal coliform, nitrate+nitrite, and flow were all statistically different comparing distribution and when corrected for central tendencies.

STILLAGUAMISH RIVER NEAR SILVANA

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data in Figures 18, 19, and 20. Temperature was significantly higher than historical median levels in WY 1991, especially during the critical summer months of July, August, and September. This elevated summer temperature in turn was reflected in lower D.O. levels. Fecal coliform levels were also high in WY 1991 with the months of February, September, and December establishing new 10-year maximum levels. The Stillaguamish had five water quality violations in WY 1991, two for temperature (July and August), and three for fecal coliform bacteria (February, September, and December).

Trends in Conventional Water Quality (10/79 - 09/91)

Significant SK Trends at the 95th probability levels were indicated for turbidity and total phosphorus (see Table 9). Turbidity was significantly correlated to flow ($R^2 = 0.352$) and the flow adjusted turbidity levels show a decrease of 2.3% per year (Figure 21). Total phosphorus also showed a significant trend, but the median of the data set was below the working quantitation limit.

Overall Water Quality

The July-September mean temperature of 16.1°C present in the six-year summary indicates, as stated above, the temperatures for WY 1991 are above normal. As for fecal coliform, the highest mean occurred during the July-September quarter, however, fecal coliform levels do not show a significant correlation to flow ($R^2 < .05$) and therefore do not point to a consistent source.

SNOHOMISH RIVER AT SNOHOMISH

Wateryear 1991

Wateryear 1991 data compared to the last 10 years of data are located in Figures 22, 23, and 24. The Snohomish River appeared to be generally within the historical range for most of the conventional parameters except for fecal coliform, pH, and suspended solids. Fecal coliform and pH were below and suspended solids were above historical median levels. The August temperature did set a new 10-year maxima and as expected, the corresponding D.O. concentration was a new 10-year minima.

Trends in Conventional Water Quality (10/79 - 09/91)

Seasonal Kendall Trend information is presented in Table 10. Significant trends were detected in half of the parameters tested including temperature, suspended solids, fecal coliform, nitrate+nitrite, and ammonia. Trends for temperature and ammonia had a significant level of serial correlation and the corresponding SK with correction were not significant. Suspended solids levels are increasing at 1.75% per year, however, the data had a strong correlation to flow (R^2 = 0.8255,) and the corresponding flow adjusted SK Tests were not significant. The remaining parameters showed decreasing trends: fecal coliform (1.62% change per year); and nitrate+nitrite (1.84%) (see Figure 25).

Overall Water Quality

The Snohomish River generally has good water quality when compared to the other core stations in the Puget Sound Basin. The primary concerns at this station are temperature and fecal coliform levels. Figure 22 shows that up to 50% of the July and August temperature levels over the last 10 years have exceeded water quality standard. The August 1991 temperature of 21.2°C was among the highest temperatures recorded at this station in the last 32 plus years of sampling. This station does express a declining SK Trend in temperature, but is limited by a strong serial and flow correlation as mentioned above. Temperature will most likely continue to be a problem at this location. Fecal coliform levels show a decreasing trend and a decline in the number of water quality violations and from all indications this station show signs of improving (see Figure 25).

SAMMAMISH RIVER AT BOTHELL

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data in Figures 26, 27, and 28. As these figures show, WY 1991 was not a typical year for conventional parameters on the Sammamish River at Bothell. Turbidity, fecal coliform, total and ortho-phosphorous, ammonia, D.O., and suspended solids were generally below, and nitrate+nitrite, flow, pH, conductivity, and temperature were above historical median levels. For WY 1991, the Sammamish River had the worst water quality of the core stations inside of the Puget Sound Basin. This station not only had the highest number of water quality violations with nine, but also had 60% of the parameters ranked in the top one or two when comparing six-year quarterly mean at core stations (see Appendix 7).

Trends in Conventional Water Quality (10/79 - 09/91)

Significant SK Trends were detected for 5 of the 12 parameters tested (see Table 11). Turbidity (-8.66% per year), fecal coliform bacteria (-2.2%), and ammonia (-6.25%) levels are decreasing. Conductivity and pH levels showed an increasing trend with a 0.9 and 0.15% change per year (see Figures 29 and 30).

Overall Water Quality

The major concerns at this station are fecal coliform levels and elevated summer temperatures. Fecal coliform levels for WY 1991, though generally below historical median levels, still had 50% of the sample exceeded the 200 organism per 100 mL water quality standard. A significant declining trend for fecal coliform was detected at the 99% levels, however, as Figure 29 shows, fecal coliform levels will continue to be a problem. As for temperature, July (20.8°C) and August (20.2°C) were elevated, but not atypical (see Figure 26) and in violation of water quality standards. These violations, combined with the lack of a significant temperature trends, indicate temperature will also continue to be a problem. It should be noted in the discussion of elevated summer temperature on the Sammamish River, however, that the primary source of water to the river is from Lake Sammamish and therefore a significant portion of the elevated temperatures may not be directly related to in-stream conditions.

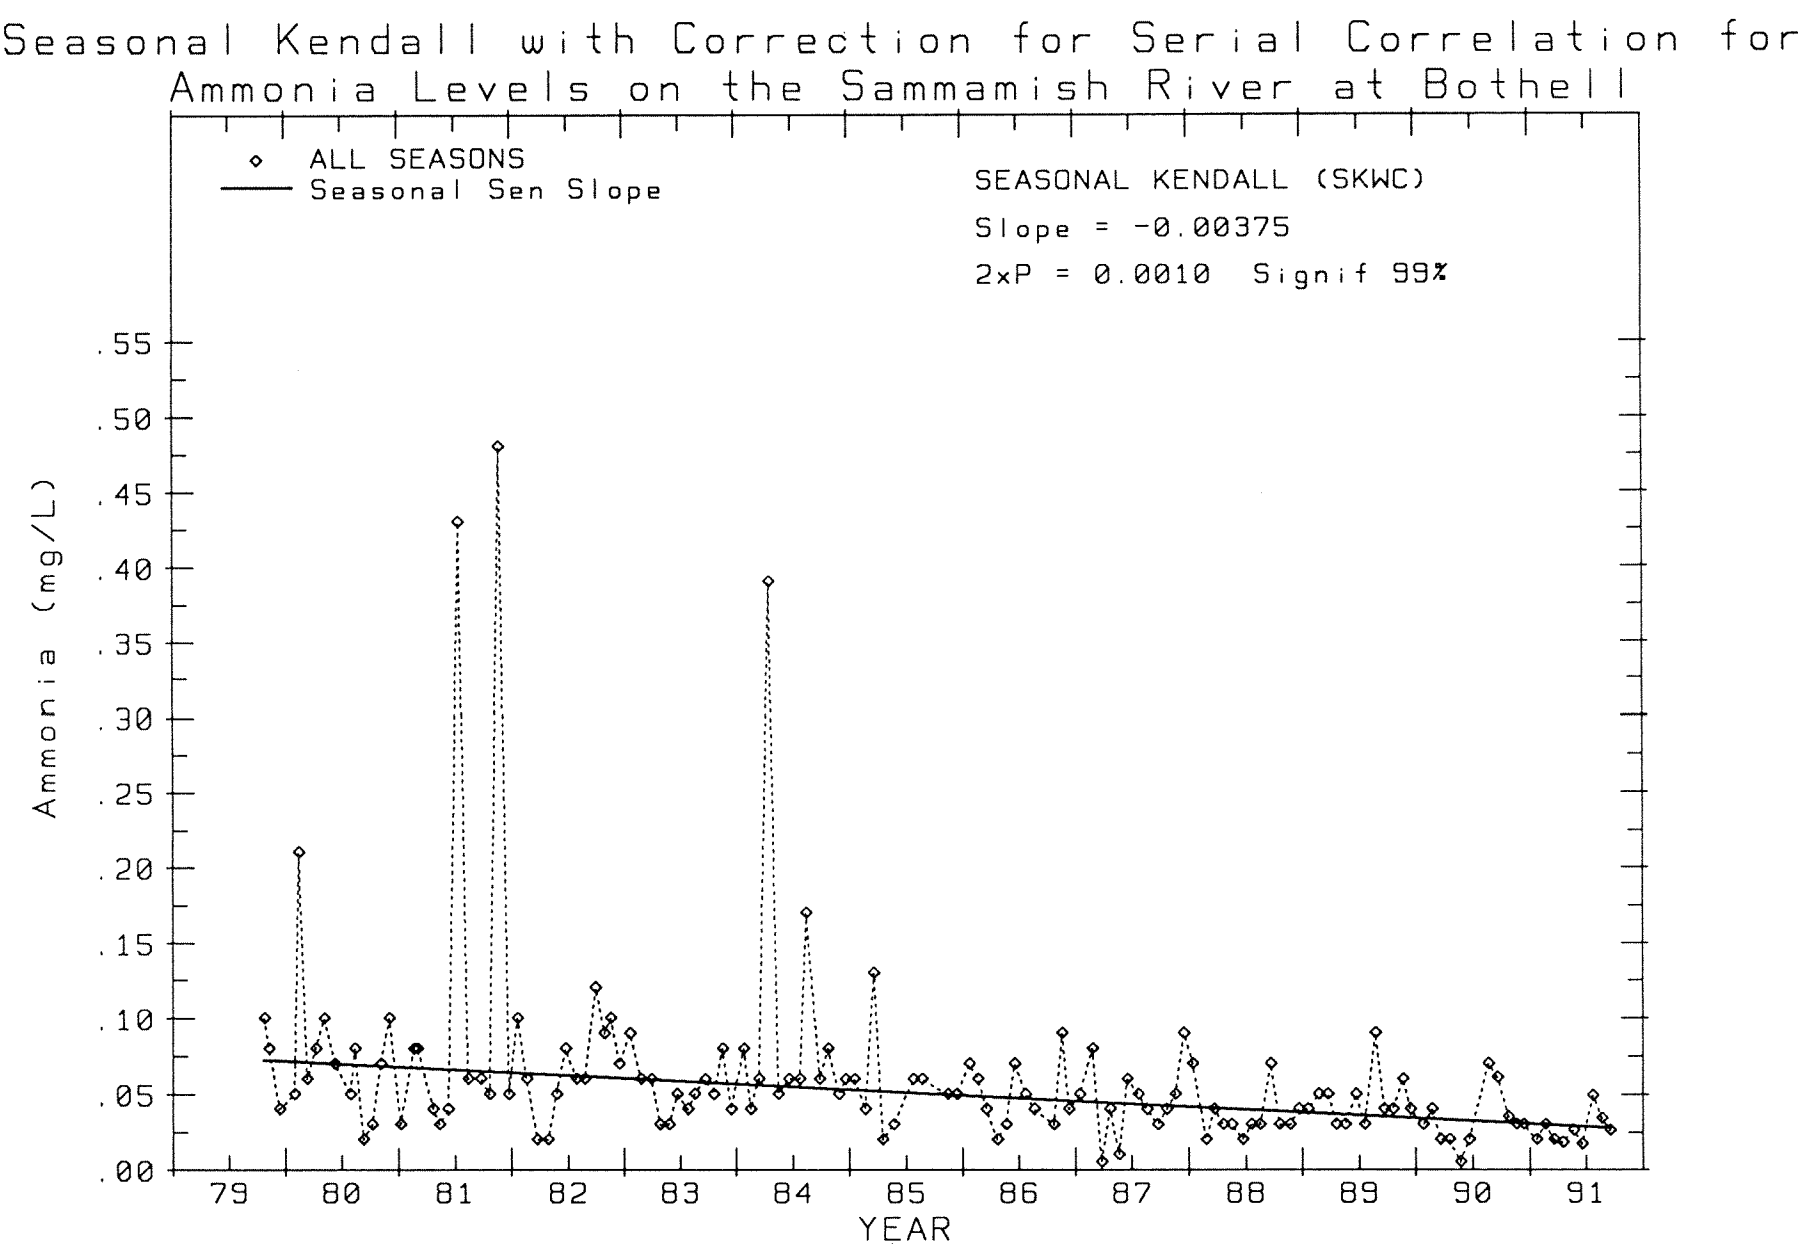

Figure 30. Significant trend graph for the Sammamish River at Bothell.

CEDAR RIVER AT RENTON

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data in Figures 31, 32, and 33. As these figures show, levels for WY 1991 conventional parameters were generally within the expected historical ranges. Flow and nitrate+nitrite were sightly above, with the remaining parameters average to slightly below historical median levels. This station did not violate water quality standards in WY 1991.

Trends in Conventional Water Quality (10/79 - 09/91)

Significant SK Trends were detected for temperature, conductivity, turbidity, total phosphorus, and ammonia (see Table 12). Temperature, turbidity, and total phosphorus, however, showed serial correlation and the corresponding corrected trends were not significant. Conductivity showed an increasing flow adjusted trend with a 0.43% change per year. Ammonia levels express a declining trend with a 7.84% change per year (see Figure 34).

Overall Water Quality

The Cedar River Station appears to have some of the better water quality of the core stations inside of the Puget Sound Basin. This station has occasionally violated water quality standards over the last 10 years but most of these violations were 10-year maxima. The only exception is fecal coliform bacteria, where 25% of the samples exceeded standards from August through October.

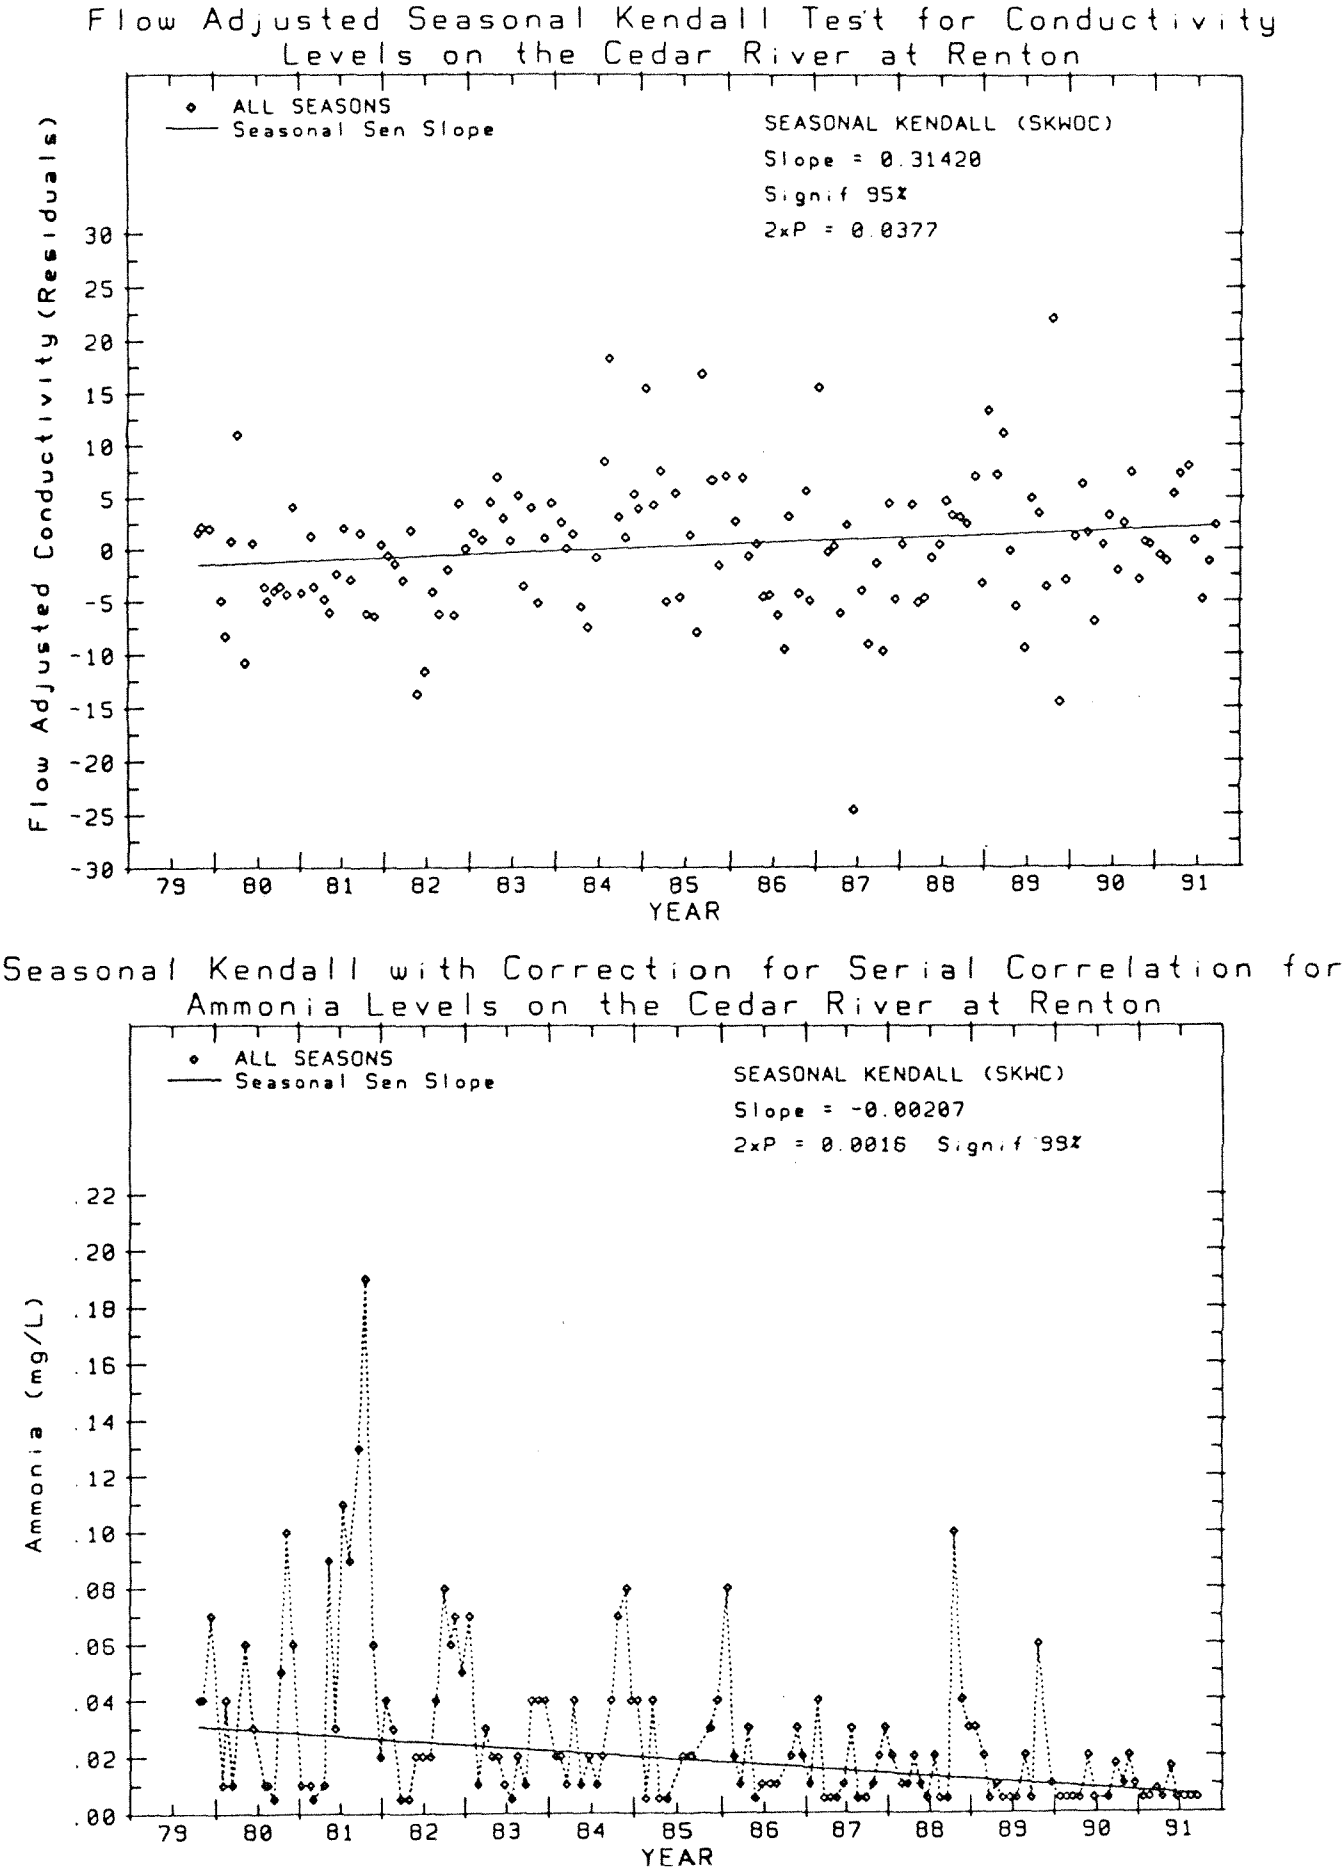

Figure 34. Significant trend graphs for the Cedar River at Renton.

GREEN RIVER AT TUKWILA

Wateryear 1991

In December 1990, the lower Green River core station was moved from river mile (RM) 8.3 (Green/Duwamish at Allentown) to RM 12.4 (Green River at Tukwila) in order to reduce tidal influence. This move was facilitated by the removal of the Renton Treatment Plant outfall from the Green River in 1987, one of the primary reasons for locating the station at RM 8.3. In WY 1991, the Green River at Tukwila violated water quality standards three times; twice for temperature (July, 18.7°C; and August, 19.9°C), and once for fecal coliform (February, 820 organisms per 100 mL).

Trends in Conventional Water Quality (10/79 - 09/91)

The removal of the Renton Treatment Plant outfall from the Green River in May of 1987, represents an appropriate situation to test for the presence of a step trend. The Wilcoxon-Mann-Whitney Test for step trends was used in place of the SK Trend analysis. The new core station on the Green River does not have the required data set for trend analysis, therefore, analysis will be completed on the station at RM 8.3. Table 13 shows the results of this analysis. Most parameters showed improvement after the removal of the outfall with the most significant change in nutrients levels. The corresponding trend plots for nutrients are included in Figure 35.

Overall Water Quality

The Green River at Allentown had some of the worst water quality as reflected in the six-year summaries in Appendix 7. When comparing the highest quarterly mean levels in Appendix 7, this station ranked in the top two in all but three of the conventional parameters. It should be pointed out that the six-year data summaries still reflect discharge by the Renton Treatment Plant. The presence of significant step trends with relatively large percent change for most of the parameters suggest that in-stream conditions have improved.

Table 13. Wilcoxon-Mann-Whitney Step Trend Test on the Green/Duwamish River at Allentown Bridge with the step based on the removal of the Renton Treatment Plant outfall (May 1987).

Parameter	Significance	▵ Y	Mean BR	% change

GREEN RIVER NEAR KANASKAT

Wateryear 1991

This station is the second of two bench mark stations monitored inside of the Puget Sound Basin. Similar to the other bench mark station, Skagit River at Marblemount, most of the data except for temperature, D.O., pH, and nitrate+nitrite generated at this station were near the lower range of data found in the Puget Sound Basin. Wateryear 1991 data are compared to the last 10 years of data in Figures 36, 37, and 38.

Trends in Conventional Water Quality (10/79 - 09/91)

Seasonal Kendall Trend information is presented in Table 14. Significant decreasing trends were detected for turbidity and ammonia, however, both had median values fall below the working quantitation limit of the test.

Overall Water Quality

The Green River near Kanaskat Station has very good water quality with only occasional water quality violations over the last 10 years.

Upstream/Downstream Comparison

The removal of the Renton Sewage Treatment Plant (STP) outfall from the Green River make upstream/downstream comparisons over the entire data set difficult. Therefore, data at both stations were compared before (10/80 to 9/86) and after (5/87 to 12/90) the removal of the outfall. Table 15 presents results of the statistical analysis of the before and after paired water quality information. The individual data pairs for each parameter are presented graphically in Appendix 10.

The results of the Klotz's Statistical Test indicate (see Table 15) all parameters have significant ($<95\%$) difference distribution and therefore only the Anderson-Darling Test was used for further statistical analysis (Wilcoxon-Mann-Whitney requires populations of similar shapes). The Anderson-Darling Test and the Anderson-Darling corrected for central tendency showed all of the parameters were statistically different at the $\geq 95\%$ confidence level before the removal of the outfall. The after-paired data sets, with the exception of temperature, and the median corrected Anderson-Darling nitrate+nitrite were still statistically different. However, as presented graphically in Appendix 10, differences between mean concentration at Allentown Bridge and Kanaskat has decreased with the removal of the Renton STP outfall, especially for ammonia, total and ortho-phosphorus, fecal coliform, D.O., and percent saturation.

Klotz - Nonparametric test of equality of variances/spread (populations of equal shape. significant results indicate data set do not have equal variance and A-D should be used.

Paired Wilcoxon - Nonparametric test for difference between means (assumes populations of equal shape). Significant test indicated the mean are different.

Anderson-Darling - Nonparametric test for difference between distributions (does not assume populations of equal shape).

L & S/R - Compares Central tendencies and spread/variance between stations.

S/R only - Tests scale and range (spread/variance) only by normalizing the data by subtracting the median (removes central tendencies) and retesting the new data set. Compares spread/variance only.

NS - Not significant.

PUYALLUP RIVER AT MERIDIAN STREET BRIDGE

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data in Figures 39, 40, and 41. As these figures show, WY 1991 was a highly variable year for most of the parameters. Fecal coliform, turbidity, pH, suspended solids, conductivity, and nutrients all ranged from lower to higher than normal historical median levels. Flow was the only remaining parameter to be above historical median levels; the rest were near or sightly below historical median levels. This station had five water quality violations in WY 1991, all of which were fecal coliform.

Trends in Conventional Water Quality (10/79 - 09/91)

Seasonal Kendall Trend information is provided in Table 16. Significant trends were detected for temperature, conductivity, nitrate+nitrite, turbidity, pH, and ammonia. Temperature, turbidity and ammonia show declining trends of -1.41, -1.39 and -4.17% per year. The ammonia trend, however, may reflect the reduction of noise in the method of analysis, especially near detection limits, and not reflect in-stream changes. Conductivity and nitrate+nitrite are increasing at about 0.87% and 7.74% per year, respectively (Figures 42 and 43). Trends for the remaining conventional parameters are limited by serial correlation or were not significant when flow adjusted concentrations were analyzed.

Overall Water Quality

The Puyallup River had some of the poorer water quality of core stations inside of Puget Sound. This station had some of the highest quarter mean concentrations for fecal coliform, suspended solids, total phosphorus, ortho-phosphorus, and turbidity levels for stations inside of the Puget Sound Basin over the last six years (Appendix 7). Elevated suspended solids and turbidity can be largely attributed to glacial till, a natural condition on the Puyallup River. Of the remaining parameters, elevated fecal coliform levels appear to be of the greatest concern. Fecal coliform levels will probably continue to be a problem at this station due to: 1) the absence of declining trend in the long- term data set; 2) the high number of fecal coliform violations over the last 10 years, and 3) the continuing high number of fecal coliform violations (five) in WY 1991.

NISQUALLY RIVER AT NISQUALLY

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data in Figures 44, 45, and 46. As these figures show, levels for most conventional parameters were generally within the expected historical ranges with the exception of nitrate+nitrite levels. Nitrate+nitrite levels for WY 1991 were all at or above the historical median levels. Suspended solids, turbidity, conductivity, and pH were variable, ranging from sightly above to slightly below historical median levels. This station did not violate water quality standards in WY 1991.

Trends in Conventional Water Quality (10/79 - 09/91)

Table 17 presents SK Trend information for the Nisqually River at Nisqually. Significant trends were expressed in 6 of the 12 parameters tested. Conductivity and pH showed increasing trends of 0.82, and 0.41% change per year, respectively. Turbidity, fecal coliform, and ammonia, are declining at -1.76, -0.12 and -4.93% change per year. Nitrate+nitrite showed a strong serial correlation and also was correlated to stream flow ($R^2 = 0.5433$). The flow adjusted SK with correction for serial correlation indicated nitrate+nitrite levels are increasing at 2.03% per year (see Figures 47 and 48).

Overall Water Quality

The Nisqually River has some of the best water quality of the core stations inside of Puget Sound, with only occasional water quality violations over the last 10 years, most of which were also monthly maxima or minima. However, nitrate+nitrite levels do appear to be increasing.

SKOKOMISH RIVER NEAR POTLATCH

Wateryear 1991

Wateryear 1991 data are compared to the last 10 years of data in Figures 49, 50, and 51. For WY 1991 fecal coliform, flow, pH, conductivity, and D.O. levels were variable. Nitrate+nitrite levels for June, July, and August set three new 10-year monthly maximums and nine of the 12 samples for WY 1991 were above historical median levels. Temperature, turbidity, ammonia, and suspended solids were at to slightly above historical median levels when compared to the last 10 years of data. Total and ortho-phosphorus were the only parameters below normal. In WY 1991, this station had only one pH value in violation of state water quality standards.

Trends in Conventional Water Quality (10/79 - 09/91)

Table 18 presents SK Trend information for the Skokomish River. Conductivity, fecal coliform, ammonia, total and ortho-phosphorus, and nitrate+nitrite all expressed significant trends, however, all except conductivity had medians below the working quantitation limit or were not significant when flow adjusted. Flow adjusted conductivity is increasing at 0.78% per year (see Figure 52).

Overall Water Quality

The Skokomish River is among the core stations that had the best water quality inside of Puget Sound. This river has only occasionally violated water quality standards over the past 10 years.

APPENDIX 2

Washington State Department of Ecology Ambient Monitoring Station Locations

Appendix 2. Washington State Department of Ecology Ambient Monitoring Station Locations

Core Stations

1. Nooksack River at Brennan
2. Skagit River near Mount Vernon
3. Stillaguamish River near Silvana
4. Snohomish River at Snohomish
5. Sammamish River at Bothell
6. Cedar River at Renton
7. Green River at Tukwila
8. Puyallup River at Meridian St. Bridge
9. Nisqually River at Nisqually
10. Skokomish River near Potlatch
11. Chehalis River at Porter
12. Cowlitz River at Kelso
13. Humptulips River at Humptulips
14. Columbia River at Umatilla
15. Yakima River at Kiona
16. Wenatchee River at Wenatchee
17. Methow River near Pateros
18. Okanogan River @ Malott
19. Similkameen River at Oroville
20. Walla Walla River near Touchet
21. Snake River at Pasco
22. Palouse River at Hooper
23. Snake River at Interstate Bridge
24. Spokane River at Mouth
25. Spokane River at Riverside State Park
26. Spokane River at Stateline Bridge
27. Columbia River at Northport
28. Pend Oreille River at Newport

Bench Mark Stations

1. Skagit River at Marblemount
2. Green River at Kanaskat
3. Chehalis River near Dryad
4. Wenatchee River near Leavenworth
5. Palouse River at Palouse

Appendix 2. Continued.

Rotating Stations

1. Nooksack River @ North Cedarville
2. Sumas River near Huntingdon B.C.
3. Whatcom Creek @ Bellingham
4. Samish River near Burlington
5. Friday Creek below Hatchery
6. Skagit River at Concrete
7. Baker River at Concrete
8. Sauk River near Rockport
9. S.F. Stillaguamish River @ Arlington
10. S.F. Stillaguamish River near Granite Falls
11. N.F. Stillaguamish River near Cicero
12. N.F. Stillaguamish River near Darrington
13. Pilchuck River @ Snohomish
14. Skykomish River @ Monroe
15. Skykomish River near Gold Bar
16. Snoqualmie River near Monroe
17. Snoqualmie River near Carnation
18. Snoqualmie River @ Snoqualmie
19. Sultan River @ Sultan
20. Wood Creek @ Monroe
21. Tolt River near Carnation
22. Sammamish River @ Redmond
23. Issaquah Creek near Issaquah
24. Cedar River @ Maple Valley
25. Cedar River near Landsburg
26. Ship Canal @ Fremont
27. Green River @ 212th Street near Kent
28. Green River near Black Diamond
29. Big Soos Creek near Auburn
30. Mill Creek near Kent on W. Valley Highway
31. Puyallup River at Orting
32. Carbon River near Orting
33. White River @ Sumner
34. White River near Buckley
35. Nisqually River @ McKenna
36. Chamber Creek near Steilacoom
37. Deschutes River @ E Street Bridge
38. Deschutes River near Rainier
39. Goldsborough Creek near Shelton
40. Hamma Hamma near Eldon
41. Duckabush River near Brinnon
42. Dosewallips River @ Brinnon
43. Big Quilcene River near Quilcene
44. Dungeness River near Sequim
45. Elwha River near Port Angeles
46. Soleduck River near Forks
47. Hoh River at DNR Campgrounds
48. Queets River at Queets
49. Quinault River at Lake Quinault
50. WF Hoquiam River near Hoquiam
51. Satsop River near Satsop
52. Newaukum River near Chehalis
53. Skookumchuck River at Chehalis
54. Black River at Moon Road Bridge
55. Chehalis River a Montesano
56. North River near Raymond on Highway 101
57. Willapa River near Willapa
58. Willapa River at Lebam
59. Naselle River near Naselle
60. Cowlitz River at Toledo
61. Toutle River near Castle Rock
62. Coweeman River at Kelso
63. Kalama River near Kalama
64. Lewis River at County Road 16
65. EF Lewis River near Dollar Corner
66. Washougal River at Washougal
67. Yakima River at Parker
68. Naches River at Yakima on US97
69. Tieton River at Oak Creek
70. Cle Elum River near Roslyn
71. Teanaway River near Cle Elum
72. Icicle Creek near Leavenworth
73. Columbia River at Chelan Station
74. Methow River at Twisp
75. Okanogan River at Oroville
76. Nespelem River at Nespelem
77. Klickitat River near Lyle
78. Klickitat River near Pitt
79. Columbia River near Vernita

Appendix 2. Continued.

Rotating Stations (Cont.)

80. Entiat River near Entiat
81. Chelan River at Chelan
82. Touchet River at Touchet
83. Touchet River near Dayton
84. Palouse River near Diamond
85. SF Palouse River at Pullman
86. Rock Creek near Revere
87. Tucannon River at Powers
88. Grande Ronde River near Anatone
89. Asotin Creek at Asotin
90. Sanpoil River at Keller
91. Sanpoil River above Republic
92. Columbia River at Grand Coulee
93. Hangman Creek at Mouth
94. Crab Creek near Beverly
95. Crab Creek near Moses Lake
96. Little Spokane River near Mouth
97. Colville River at Kettle Falls
98. Kettle River near Barstow
99. Pend Oreille River at Metaline Falls

Floating Stations

Numbers depend on budget remaining after factoring in monitoring cost for core/bench mark and rotating stations.

APPENDIX 3

Current Laboratory Methods for the Department of Ecology's Freshwater Ambient Monitoring Program

Appendix 3. Current laboratory methods for the Department of Ecology's Freshwater Ambient Monitoring Program.

1. Fecal coliform:

Bottle type	-	Glass
Sample volume	-	200 mL
Preservative	-	Store at 4°C
Holding Time	-	30 hours
Analytical Method	-	Standard Methods for the Examination of Water and Wastewater, 16th Ed., No. 214A, Standard Methods, 16th Ed., No. 909c, "Fecal Coliform Membrane Filter Procedure," pp. 896

2. Conductivity: Field

Bottle type	-	Polyethylene
Sample volume	-	200 mL
Preservative	-	None
Holding Time	-	NA
Analytical Method	-	Modification of Standard Methods for the Examination of Water and Wastewater, 16th Ed., No. 205, "Conductivity," pp. 76-80.

3. Total Hardness:

Bottle type	-	Polyethylene
Sample volume	-	500 mL
Preservative	-	Store at 4°C
Holding Time	-	6 Months
Analytical Method	-	Standard Methods for the Examination of Water and Wastewater, 16th Ed., No. 1348, "EDTA Titrimetric Method," pp. 210-14.

4. Ammonia Nitrogen:

Bottle type	-	Polyethylene
Sample volume	-	125 mL
Preservative	-	Sulfuric Acid, at 4°C
Holding Time	-	28 Days
Analytical Method	-	EPA Method 350.1, automated Phenate.

5. Nitrate+Nitrate Nitrogen:

Bottle type	-	Polyethylene
Sample volume	-	125 mL
Preservative	-	Sulfuric Acid, 4°C
Holding Time	-	28 Days
Analytical Method	-	EPA Method 353.2, Colorimetric, Automated, Cadmium Reduction.

Appendix 3. Continued.

6. Nitrite Nitrogen:

Bottle type	-	Polyethylene
Sample volume	-	125 mL
Preservative	-	Amber Bottle, 4°C
Holding Time	-	48 Hours
Analytical Method	-	Adaptation of EPA Method 353.2, Colorimetric, Automated, Cadmium Reduction.

7. pH: Field

Bottle type	-	Polyethylene
Sample volume	-	200 mL
Preservative	-	None
Holding Time	-	NA
Analytical Method	-	Modification of Standard Methods for the Examination of Water and Wastewater, 16th Ed., No. 423, "pH Value," pp. 429-37.

8. Ortho-phosphorus:

Bottle type	-	Polyethylene
Sample volume	-	125 mL
Preservative	-	Filter, Amber Bottle, 4°C
Holding Time	-	48 Hours
Analytical Method	-	EPA Method 365.1, Colorimetric, Automated Ascorbic Acid.

9. Total Phosphorus:

Bottle type	-	Polyethylene
Sample volume	-	125 mL
Preservative	-	H_2SO_4, Store at 4°C
Holding Time	-	28 Days
Analytical Method	-	EPA Method 365.1, Colorimetric, Automated, Ascorbic Acid

10. Total Suspended Solids:

Bottle type	-	Polyethylene
Sample volume	-	1000 mL
Preservative	-	Store at 4°C
Holding Time	-	7 Days
Analytical Method	-	Standard Methods, 16th Ed., No. 209c, "Total Suspended Solids Dried at 103-105oC." p. 96-97.

Appendix 3. Continued.

11. Turbidity

Bottle type	-	Polyethylene
Sample volume	-	500 mL
Preservative	-	Store at 4°C
Holding Time	-	48 hours
Analytical Method	-	Standard Methods for the Examination of Water and Wastewater, 16th Ed., No. 214A, "Nephelometric Method-Nephelometric Turbidity Units," pp. 134-36.

12. Mercury (Cold Vapor AA)

Bottle type	-	Polyethylene (Cubitainer) with Teflon Lid
Sample volume	-	1 L
Preservative	-	Store at 4°C
Holding Time	-	28 days
Analytical Method	-	EPA 600/4-79-020,4.1.1. SW846, Volume 1, Section A. EP1-245.1

13. Cadmium (Total Recoverable/AA)

Bottle type	-	Polyethylene (Cubitainer) with Teflon Lid
Sample volume	-	1 L
Preservative	-	Store at 4°C
Holding Time	-	6 months
Analytical Method	-	EPA 600/4-79-020,4.1.1. SW846, Volume 1, Section A. EP1-213.R

14. Chromium (Total Recoverable/AA)

Bottle type	-	Polyethylene (Cubitainer) with Teflon Lid
Sample volume	-	1 L
Preservative	-	Store at 4°C
Holding Time	-	6 months
Analytical Method	-	EPA 600/4-79-020,4.1.1. SW846, Volume 1, Section A. EP1-218.R

15. Lead (Total Recoverable/AA)

Bottle type	-	Polyethylene (Cubitainer) with Teflon Lid
Sample volume	-	1 L
Preservative	-	Store at 4°C
Holding Time	-	6 months
Analytical Method	-	EPA 600/4-79-020,4.1.1. SW846, Volume 1, Section A. EP1-239.R

Appendix 3. Continued.

16. Zinc (Total Recoverable/ICP)

Bottle type	-	Polyethylene (Cubitainer) with Teflon Lid
Sample volume	-	1 L
Preservative	-	Store at 4°C
Holding Time	-	6 months
Analytical Method	-	EPA 600/4-79-020,4.1.1. SW846, Volume 1, Section A. EP1-200.7

17. Copper (Total Recoverable/ICP)

Bottle type	-	Polyethylene (Cubitainer) with Teflon Lid
Sample volume	-	1 L
Preservative	-	Store at 4°C
Holding Time	-	6 months
Analytical Method	-	EPA 600/4-79-020,4.1.1. SW846, Volume 1, Section A. EP1-200.7

APPENDIX 4

Wateryear 1991 Raw Data and Six-Year Summary Statistics for the Department of Ecology's Freshwater Ambient Monitoring Program

FROM: Brad Hopkins

SUBJECT: Upper Snoqualmie River Special Study

At the request of the Northwest Regional Office (NWRO), the Ambient Monitoring Section collected water quality information during low flow conditions (June-September 1991) at three additional locations (see Figure 1) on the Snoqualmie River. They were as follows:

Station #	Description
1) 07N070	North Fork of the Snoqualmie River near Ellisville--River Mile 44.9, 0.3; Lat 46 59 43; Long 121 46 07
2) 07D150	Middle Fork of the Snoqualmie River near Ellisville--River Mile 45.3; Lat 47 07 06; Long 121 46 06
3) 07M070	South Fork of the Snoqualmie River at North Bend--River Mile 44.4, 2.01; Lat 47 33 12; Long 121 47 23

Water quality information generated at these locations will be used by the NWRO to evaluate possible outfall locations and to develop a water quality based permit for a planned WWTP expansion. Regional staff specifically expressed interest in background metals concentrations present during low flow conditions.

Attachment 1 and the enclosed floppy disk provide all of the current water quality information on the Snoqualmie River collected by our section from June-September 1991, including the two mainstem stations at the city of Snoqualmie and near Carnation. To compare data between stations, this same information is provided by date rather than by station in Table 1.

General Water Quality

Upper River

The general water quality at all three locations was, for the most part, very good, with the majority of the parameters within the expected range of waters of high quality. The only exceptions were five violations of Washington State Water Quality Standards as highlighted in Table 1 (see Attachment 2 for specific standards). The August temperature violations of 17.7 and 16.2°C (Class AA Criteria < 16°C) on the Middle and North Forks are most likely the result of combined effects of reduced flow and high ambient temperatures--a natural condition. Dissolved oxygen violations for the same time period of 9.4 and 8.9 mg/L (Class AA Criteria > 9.5 mg/L), show a weakness in the water quality standards, and do not reflect instream conditions. This weakness becomes evident upon review of the percent saturation for dissolved oxygen, which show both stations are above 90% of saturation level with 90.6 and 98.9 percent. The remaining two violations, pH of 6.4 and fecal coliform of 100 colonies per 100 mL of sample, for September are at or near the water quality criteria (6.5-8.5 for pH and < 10% of the samples may exceed 100 organisms for fecal coliform).

Mainstem

The water quality for the mainstem Snoqualmie Stations, at Snoqualmie and Carnation, were all within Class A Water Quality Standard (see Attachment 2), with the exception of an August temperature violation at the Carnation stations of 20.0°C (Class A Criteria <18°C).

Metals

Metals concentrations at the three new locations and the corresponding water quality criteria are presented in Table 2. Most of these concentrations are at or near detection limits as denoted by the qualifier codes attached to the data. However, one cadmium value of 0.32 µg/L on the North Fork collected in June does exceed both the calculated acute (0.26 µg/L) and chronic (0.17 µg/L) criteria. This datum may be a laboratory artifact as an inordinately high number of detect were present for the June Northwest ambient monitoring samples. However, a review of the laboratory QA does not indicate a problem. Even if the datum is a valid concentration it should be noted that it is a total recoverable concentration, where as the standards are based on dissolved concentrations. This problem of different methods between water quality values and the standard to which they will be compared, will continue until EPA approves an acid-soluble (dissolved) method. In the interim, EPA recommends applying the criteria using the total recoverable method, even though these criteria may be overly protective.

Detection limits currently available for Hg, Cu, Pb, and Cd are in very close proximity to the chronic criteria, and may lead to overly restrictive permit conditions if the data provided in Table 2 is to be used in the WQBP-TOX.WK1 spreadsheet. It is my recommendation

SUBJECT: Little Spokane River Study -- Final Report

BACKGROUND

In March, 1989, Ecology included the Little Spokane River on Washington's 304(L) mini-list as water quality impaired due to toxics because of mercury and cyanide contamination. This assessment was based in part on Ambient Monitoring Section (AMS) mercury data for WY87 and WY88 which showed occasional mercury levels in excess of EPA's chronic criteria of 0.012 μg/L.

Because Manchester Lab's detection limit for mercury was 0.02 μg/L, above the chronic criteria level, a water quality standards violation was assumed any time mercury was detected in the monthly samples. However, not only is a fairly large amount of uncertainty associated with values below the quantitation limit (approximately 10 times the detection limit), but the standards specify a four-day average value.

The Eastern Regional Office (ERO) requested that AMS determine whether or not a mercury problem actually exists in the Little Spokane River; and if mercury contamination is found, to identify which general area within the basin is the source of the contamination. In addition, ERO requested we sample the usual suite of conventional constituents in order to further characterize general water quality in the basin.

METHODS

AMS and ERO identified four stations within the Little Spokane River drainage, in addition to AMS' routine ambient monitoring station near the mouth (Table 1).

These five stations were sampled monthly from July 1990 through June 1991. Conventional constituents were sampled at all stations and total metals (Hg, Cu, Pb, Cd, Cr, and Zn) were sampled at the Little Spokane near the mouth in accordance with AMS' standard protocols

(Hopkins, *et al.*, in press) and sent to Manchester Lab for analysis. In addition, the six metals listed above were sampled at the mouth, and mercury was sampled at the remaining four stations for analysis at Battelle Marine Research Laboratory in Sequim, Washington. All metals were collected directly into the sample containers by attaching the containers to a stainless steel holder and lowering the apparatus into the water via a rope. Battelle Lab's samples were collected in teflon bottles previously cleaned by heating in concentrated reagent grade HNO_3 for 48 hours at 90°C, then rinsed five times in deionized water and dried in a laminar flow clean-air bench. Acid preservative (8% HCl) was added in the field, and the bottles placed in zip-lock bags and shipped on ice to the Battelle Lab via Manchester.

Battelle Lab extracted metals with ammonium pyrrolidine dithiocarbamate for Cu, Pb, and Cd, followed by analysis by graphite furnace (Bloom and Crecelius, 1984). Cr and Zn were analyzed directly by graphite furnace. Mercury was analyzed by cold vapor AA (Bloom and Crecelius, 1983). Battelle's results were blank-corrected. Data analysis and graphics were done using WQHYDRO (Aroner, 1991).

DATA QUALITY

The quality of Manchester's data is evaluated through Manchester's continuing quality assurance/quality control (QA/QC) program which includes quality control charts, check standards, in-house matrix spikes, laboratory blanks and duplicates, and regular performance evaluation standards. In addition, AMS maintains its own QA/QC programs which includes standard sampling protocols, blind field duplicates, and blind field blanks. These QA/QC procedures and results are discussed in more detail in Hopkins, *et al.* (in press).

The quality of data from Battelle lab was generally good. The results of an analysis of a performance evaluation sample for Hg were good, although a little low. Where QC results were not within acceptable limits data are flagged with the appropriate remark code. Reviews of Battelle's data by Craig Smith are attached.

RESULTS AND DISCUSSION

Mercury Contamination

Manchester Lab reported results above detection limits for five of the 12 monthly mercury samples from the routine monitoring station near the mouth (Table 2). However, all five were flagged 'J' (estimate) or 'P' (below quantitation limits). (During the first part of the study 'P' was not used and Manchester flagged values below quantitation limits with 'J'.) A field duplicate was collected from the Little Spokane River near the mouth on June 4. Manchester reported a mercury concentration of 0.14 µg/L for this sample; the original sample result was 0.04P µg/L. Manchester was unable to explain the differences between the two values, but given that the result from the first sample was flagged and Battelle's result was well below the criteria, I do not feel a violation of standards occurred.

With exception of one sample date, Battelle Lab's mercury results were approximately an order of magnitude below chronic criteria at all stations (Table 3). Three values in March were above chronic criteria for mercury. These results were from the Little Spokane River stations near Griffith Springs, above Dartford Creek, and above Peone Creek. The mercury concentration near Griffith Springs was two to three orders of magnitude greater than all other results and results from the two upper-most stations were one to two orders of magnitude greater. Battelle re-ran the Griffith Springs sample with nearly identical results. I am inclined to believe these results represent true environmental concentrations. Sample contamination would not explain violations at all three upstream stations: it is unlikely that three samples in March would be contaminated with no contamination problems encountered during the rest of the study. Batch contamination would not explain the low values near the mouth and in Peone Creek. The high mercury results were not correlated with suspended sediment or discharge; these were both greatest at all stations in February.

One explanation for these results is that a pulse of mercury originating upstream of our upper-most station was moving through the system. The pulse had not yet reached the mouth when we sampled, and had, for the most part, passed the upper two stations at the time of sampling. Because travel time between the upper and lower stations is only about six hours, water quality standards for the chronic criteria, which specify a four-day average, were not exceeded. EPA (1986) states that "freshwater aquatic organisms and their uses should not be affected unacceptably" if the four-day chronic criteria is not exceeded. All results were well below the acute criteria of 2.4 μg/L.

At the time the 304(L) list was prepared identifying the Little Spokane River as an area of concern, data between detection and quantitation limits were not qualified and residence time was not considered. Had they been, all the data except one result would have been qualified. That one result, 0.45 μg/L collected October 3, 1989, was verified with the lab at the time. It may have been sample contamination or it may have also been the result of a pulse.

Other Metals Results

Manchester Lab's results exceeded both the tenth percentile and the specific chronic criteria for copper and lead at the Little Spokane River near the mouth in February and March. Copper exceeded the tenth percentile for criteria in June, but the actual chronic criteria value for that date were not exceeded. No values exceeded drinking water criteria. The reasons for these exceedances are unknown. However, February and March were the two highest flow months indicating the source was probably not point-related. Because concentrations were high in both February and March, the four-day average probably exceeded the criteria and water quality standards were violated for Cu and Pb.

Battelle Lab's results for both copper and lead exceeded the tenth percentile in February, and lead exceeded the tenth percentile for the criteria in March (Table 2). The actual chronic criteria values for February (but not March) were also exceeded, based on hardness values for those dates.

Battelle Lab's results were almost always lower than Manchester Lab's, particularly where Manchester's was qualified "J" or "P". This is inevitable, given that most concentrations were below Manchester Lab's detection limits but above Battelle's. There were a number of samples which Manchester quantified as above detection limits but below quantitation limits and which were, therefore, qualified. The differences between the results from these two labs highlight both the difficulty in accurate analysis for whole-water metals, and the importance of interpreting results below the quantitation limit with great caution.

Conventional Water Quality

Conventional water quality was generally fair (Table 4). Individual results from all stations are attached. Figures 1 through 5 illustrate the distribution of oxygen, pH, temperature, fecal coliform bacteria, and total ammonia at each main stem Little Spokane station by river mile. Lines representing water quality standards are also plotted. These distribution plots should be considered conditional since they are based at most on only 12 samples at each station.

Several water quality standards were violated during the course of the study (Table 5) with the Little Spokane River above Dartford Creek displaying the most violations.

Upstream summer temperatures were dramatically higher than downstream temperatures between RM 7.5 and RM 10.3 (Figure 1). Temperatures at the two upper stations and Peone Creek may be expected to exceed (violate) state standards nearly 25% of the time. Temperatures at the lower two stations may be kept below standards by dilution with (presumably) cooler groundwater inflow and Waikiki Springs, although without knowing the temperature and flow of these sources, this is only conjecture.

Oxygen concentrations were above criteria at all stations (there were no violations) (Figure 2). The spread between maximum and minimum concentration increased as distance upstream increased. This is not surprising: the greater volume of water downstream than upstream would be more likely to buffer diurnal and seasonal changes in oxygen. Also, the mid-reach springs would likely have a stabilizing influence on water quality in general. Median oxygen concentrations were significantly ($p=0.004$) lower at the Griffith Springs station (RM 7.5) than at the station above Dartford Creek (RM 10.3). Percent saturation also increased with increasing river mile. The lower two stations were generally below saturation while the upper two were above saturation. This may indicate a decrease in the production:respiration ratio downstream relative to upstream, a lower downstream reaeration coefficient, or the influence of the springs.

Distributions of pH were similar at all stations with the exception of the station above Dartford Creek (RM 10.3) and the Peone Creek station which may both be expected to violate state standards more than 25% of the time (Figure 3 and Table 4).

All stations except Peone Creek exceeded (violated) fecal coliform bacteria standards (Table 4). That is, the 10th percentile was greater than 200 organisms/100 mL. In general, fecal coliform counts increased with increasing river mile (Figure 4). The uppermost station (above Peone Creek) had the lowest median value of all stations, but this station also had the highest single

value, 2100 organisms/100 mL on February 5, 1991. This is also the date where streamflow was highest near the mouth, indicating a nonpoint source. Based on one year of monitoring, fecal coliform bacteria are a nonpoint source problem in the Little Spokane drainage.

Although the maximum total ammonia concentrations exceeded the tenth percentile (based on up to 12 data points) for chronic criteria at every station except near the mouth and the Peone Creek station (Table 4 and Figure 5), no concentration exceeded the actual criteria calculated for that particular date. In other words, no ammonia water quality standards violations occurred during the study.

Total ammonia and total phosphorus concentrations were lower in the two downstream stations and higher in the two upstream stations while nitrate+nitrite nitrogen exhibited the opposite pattern. Peone Creek had consistently low nutrients. Median ammonia concentrations were low at all stations compared to ecoregion (Omernik and Gallant, 1986) averages, while nitrate+nitrite nitrogen was high and total phosphorus was similar to other stations in the same ecoregion.

CONCLUSIONS AND RECOMMENDATIONS

1. Water quality standards for mercury were probably not violated during the study. After one year of monthly sampling at five stations in the Little Spokane River basin, three stations had unqualified mercury results exceeding chronic criteria, all in March. However, the four-day average was probably well below the chronic criteria.

2. Water quality standards for copper and lead were probably violated in February and March at the Little Spokane near the mouth.

3. Water quality violations in conventional constituents occurred at all stations but were most likely to occur at the upper stations, especially the station above Dartford Creek. Water quality at the routine ambient monitoring station at the mouth is better than upstream water quality, possibly due to the influence of springs below the station above Dartford Creek and below the station near Griffith Springs.

4. Nonpoint sources of fecal coliform bacteria should be investigated, particularly upstream of the Little Spokane River above Peone Creek station.

DATA REVIEW

By:	Craig Smith, Chemist		
PROJECT:	Eastern Routine Monitoring		
Lab Sample No:	Week #'s 28, 32, 36, 41, 45, 49 of 1990	**Report Date:**	03-19-91

Metals

Digestion: APDC Technique for extraction: Total Metals
Hg Analysis by Bloom and Crecilius(1983)

Turnaround Time: Six sample sets were received on March 5, 1991. Based upon contracted dates for deliverables, the following is a summary:

Sample Set:	286161	169 days late
	326161	155 days late
	366161	123 days late
	416161	104 days late
	456161	96 days late
	496163	48 days late

DELIVERABLES: One of the stipulated deliverables was all raw data. Raw data was not provided for Hg. They "discarded" the raw data.

All parameters requested were received except the following:
416161 separate Hg analysis
496167 separate Hg analysis

HOLDING TIME: With regard to holding time, analysis may or may not have been within the accepted criterion. No raw data was available for Hg.

REAGENT BLANK: Sample results were blank corrected by the laboratory.

MATRIX SPIKE: The targeted accuracy of matrix spikes is +/- 25% of the true value. All values were within the targeted limits.

SPIKE DUPLICATE: The target limits are +/- 20%, or +/- 1 detection limit for samples less than 5 times the detection limit. All values were within the targeted limits.

LABORATORY CONTROL SAMPLE The target is a +/- 20% recovery control limit. All values were within the targeted limits except for Zn on weeks 41, 45, and 49. The RPD was 90%. The Zn data for these three sets will receive an "N" qualifier.

SAMPLE DATA: The data may be used with the qualification attached.

N = value not within control limits.

DATA REVIEW

By: Craig Smith, Chemist
PROJECT: ERM Metals
Lab Sample No: 026163 - 026167
066163 - 066167
106163 - 106167, 109999(PE Sample)

Report Date: 06-19-91

	Collected	To Manchester	Data Received
HOLDING TIME:	01-08	01-09	06-07-91
	02-05	02-06	06-07-91
	03-05	03-06	06-07-91

Metals
Digestion: Hg-Bloom and Crecelius Method. Totals by APDC technique

HOLDING TIME: Analyses for all parameters were performed within the holding time limits.

REAGENT BLANK: The method blank showed no analyte values above the reporting detection limit except for Cr, Cu, Hg, and Zn. See data summary for the actual values. See explanation below.*

MATRIX SPIKE: The targeted accuracy of matrix spikes is +/- 25% of the true value. All values were within the targeted limits.

SPIKE DUPLICATE: The target limits are +/- 20%, or +/- 1 detection limit for samples less than 5 times the detection limit.
All values were within the targeted limits.

LABORATORY CONTROL SAMPLE The target is a +/- 20% recovery control limit. All values were within the targeted limits.

*The blank gave values above the reporting detection limit for all three sets of analyses. As a result, the affected data will receive a "B" qualifier.
For sample sets 02, 06, and 10, the Cu contamination is very low. The net affect will be negligible.

For all other parameters, the net affect is appreciable.
On sample sets 02, 06, and 10, the Hg and Zn data are most affected. For Hg, the blank corrected values are also given. This was not done for Zn.

The data may be used with the attached qualifiers.

B = analyte found in blank as well as sample. Possible/probable blank contamination.

As we discussed earlier, a PE sample was included in one of the sample sets from week 10. I gave this PE Sample the number 109999.

I sent ORMS-1, a riverine water sample. A copy of the certified data is attached.

The results that Battelle obtained for this sample were not too bad. Their blank corrected value was 0.00502 ug/L. The certified value was 0.0068 +/- 0.0013 ug/L. If you apply the -0.0013 value you get 0.0055, close to their 0.00502 value. Battelles results are a little low.

APPENDIX 7

Ranking of Core Stations Inside of Puget Sound
By Highest Quarterly Mean Value

Appendix 7. Ranking by parameter of highest quarterly mean at core stations inside of Puget Sound (except for D.O., where lowest quarterly mean are ranked).

	Temperature*	Mean	Qtr
1.	Sammamish	17.65	J-S
2.	Green	17.4	J-S
