Abstract

A Class II Inspection was conducted September 20-22, 1993, at the city of Medical Lake Wastewater Treatment facility in Spokane County, Washington. The Medical Lake facility operates an aerated lagoon connected in series with two large unaerated treatment/settling lagoons. The plant discharge flows several miles in an open channel before discharging to Deep Creek. Effluent flow meter calibration was checked and the meter was found to be accurate. Recalibration of pump flow measurements or, if necessary, the addition of an influent flow measurement device is recommended. A higher than typical BOD₅/TOC ratio was found for influent samples. TSS removal efficiency was moderate likely due to algae growth in the settling ponds. NH₃-N removal occurred in the system. Most effluent results are within the Ecology compliance order load and concentration limits, but several exceed NPDES permit limits. Effluent pH exceeded both NPDES permit and compliance order limits. Effluent TSS concentration exceeded the percent of influent concentration stipulated by the monthly NPDES permit limit. Chlorine residual appeared high and it is recommended that the minimal concentration and optimal retention time be determined to reliably achieve permit fecal coliform limits. Split sample analyses found good correspondence between samples and good correspondence between laboratories for most parameters except BOD₅. Wastewater metal concentrations were all within EPA and state water quality criteria for receiving waters. Concentrations of sludge metals did not exceed EPA criteria for the land application of municipal sludge, although fecal coliform densities exceeded Class A land application standards.

Summary

Flow Measurements

Medical Lake's effluent flow measurement device accurately reflected the Ecology flow measurements at the effluent weir. Effluent flow is reported to be only 36% of influent flow. The discrepancy may be attributed in part to evaporation and infiltration, but inaccuracies in influent flow measurement may also contribute.

Wastewater General Chemistry

Influent parameters were generally within typical ranges. A BOD₅ removal of 79% and a TSS removal of 33% were calculated with Ecology analytical results. Most NH₃-N was removed in the system. Most TOC and TSS removal occurred in the aeration basin. Low overall TSS removal efficiency and TSS increases across the treatment/settling lagoons basins suggest excessive algae growth in the two basins.

NPDES Comparisons

Effluent BOD₅ and TSS concentrations and loads were all within the compliance order monthly and weekly average limits. BOD₅ results exceeded the NPDES permit monthly concentration limit. One TSS result exceeded the NPDES permit monthly load limit, and all TSS results exceeded the permit monthly and weekly concentration limits. Plant TSS effluent concentration was greater than the 15% of influent concentration required by the monthly NPDES permit limit. Effluent pH exceeded the upper range of the permit limit and the compliance order. High pH was likely due to algae growth in the treatment/settling lagoons.

Plant flow rate and fecal coliform densities were within NPDES permit and compliance order limits. Chlorine residual appeared high and may be excessive to meet NPDES permit fecal coliform limits.

Split Samples

Comparison of Ecology lab results for Ecology and Medical Lake effluent samples showed good correspondence. Medical Lake lab results for the two BOD₅ effluent samples had a relative percent error of 39%. Both Ecology and Medical Lake influent samples correlated well for BOD₅, but showed more variability for TSS.

Comparisons between laboratories showed close TSS results, but the Medical Lake lab BOD₅ results did not closely match Ecology lab results. Fecal coliform results for both labs were uniformly low. The Cheney STP lab, which performed the analyses for the Medical Lake

facility, is not accredited. It is reported that they do not dechlorinate BOD₅ samples before testing.

Detected Organics and Priority Pollutant Metals

Arsenic, copper, selenium, and zinc were detected in the effluent. None exceeded the EPA or state water quality criteria for receiving waters.

Sludge

Sludge nutrient concentrations produce a nitrogen loading rate for land application to field crops of 1.8 to 7.3 tons dry solids/acre year. The sludge fecal coliform density exceeds the EPA Class A pathogen limitation for the land application of municipal sludge by a factor of 36. Sludge sample VOAs and BNAs were detected in low concentrations with the exception of Bis(2-Ethylhexyl)Phthalate. A land application criteria is not available for this compound. Concentrations of detected priority pollutant metals in the sludge did not exceed the EPA metals criteria for the land application of municipal sludge.

Recommendations

Flow Measurements

• Recalibration of pump measurements or the addition of an influent flow measurement device is recommended to provide more accurate plant loading measurements.

NPDES Comparisons

- Rectify excessive effluent TSS and low TSS removal efficiency by reducing retention time in the treatment/settling lagoons as a means to control algae growth.
- Confirm algae growth as the source of excessive pH in the effluent.
- Identify and maintain the minimal chlorine concentration and optimal contact time to achieve fecal coliform limits.

Split Samples

- An influent composite or grab composite sample is recommended.
- The lab which does the Medical Lake analysis needs to be accredited by July 1, 1994 to conform to Washington Administrative Code 173-220.

Introduction

A Class II Inspection was conducted at the City of Medical Lake Sewage Treatment Plant (STP) on September 20-22, 1993. Guy Hoyle-Dodson of the Washington State Department of Ecology's Toxics Investigations Section conducted the investigation. Pat Hallinan, municipal permit manager for the Department of Ecology's Eastern Regional Office, provided background information on facility operation. Medical Lake City Public Works Superintendent, Earl Davis; Public Works Maintenance Supervisor, Dan Dorshorst; and facility operator, Bill Ahlf provided information and assistance on site.

The Medical Lake STP serves a population of approximately 2900, consisting mainly of private residences and small retail businesses. The plant discharges effluent to Deep Creek a tributary of the Spokane River. An NPDES Permit (No. WA-002114-3) was issued July 1, 1977, with an expiration date of June 30, 1982. The facility is operating under an administrative extension of that permit. An additional administrative order (No. DE 91WQ-E376) was issued December 31, 1991, providing new, less stringent limitations for several permit parameters. The order will remain in effect until the construction of a planned system upgrade to be completed by October 1, 1996.

The Class II Inspection was initiated by the Department of Ecology to evaluate permit compliance and to provide information about facility loading and lagoon bottom sludge composition. Specific objectives of the inspection included:

- 1. Assess NPDES permit compliance;
- 2. Assess wastewater toxicity with priority pollutant metal scans;
- 3. Characterize solids and nutrient composition of lagoon bottom sludge:
- 4. Assess sludge toxicity with fecal coliform tests, priority pollutant organic scans, and metals scans;
- 5. Evaluate treatment facility performance;
- 6. Evaluate permittee's self-monitoring with split samples.

Setting

The Medical Lake treatment facility is located in Spokane County, Washington, just north of the city of Medical Lake (*Figure 1*). The facility uses an aerated lagoon system followed by chlorination. The city began operation of the lagoon system in 1977 and incorporated minor

modifications through the years. In 1992 aerators were added to lagoon #1 to improve secondary treatment.

The system consists of influent wetwell, a mechanically aerated primary lagoon (4.48 acres), two facultative treatment/settling lagoons (3.41 and 3.12 acres) operated in series, and a chlorine contact chamber (*Figure 2*). Raw wastewater from the wetwell is pumped to a splitter box and diverted into the primary lagoon. Pump records are used to estimate influent flow volumes.

Lagoon #1 is the principal secondary treatment unit. Five floating agitators provide aeration and also promote counterclockwise flow through lagoon #1. Flow enters at the north bank, completes a 270 degree circuit, and discharges to lagoon #2. Sludge accumulates on the lagoon bottom and has not been dredged during the life of the system.

Lagoons #2 and #3 are used primarily for settling. Mechanical agitation of their surfaces is limited to the prevention of ice build-up during the winter. Accumulated sludge has never been dredged.

Effluent from lagoon #3, the last in the series, is chlorinated and discharged to a chlorine contact chamber. A 45° V-notch weir with a Polysonics ultrasound flow meter records effluent flow rates. Discharge from the contact chamber cascades onto a rock spillway then flows down an open channel.

The discharge is atypical in that it flows for about four miles through surrounding agricultural land before emptying into Deep Creek (*Figure 1*). This connecting channel is open to a variety of non-point pollution sources. Farm animals have direct contact with the channel. Agricultural and residential runoff likely contribute additional contamination. Flow in this channel is seasonal, and during the dry season surface volumes recharge into the ground for short distances then resurface. The channel's confluence with Deep Creek was not accessible during the inspection.

Ecology's compliance order mandates that an upgraded treatment system, capable of meeting NPDES treatment limits, will be built to replace the current system no later than October 1, 1996. A new mechanical system which discharges to Medical Lake is presently under design.

Procedure

Ecology collected both grab and composite samples at the STP. Composite samples were collected from wastewater at two stations (*Figure 2 & Appendix A*); the influent wetwell and the effluent from the chlorination chamber. All composite samples were collected using Ecology ISCO composite samplers with equal volumes of the sample collected every 30 minutes over a 24 hour period. Grab samples were collected at all composite stations as well as several other sites.

Medical Lake personnel collected grab samples at the influent splitter box and from the effluent at the outfall from the chlorine contact chamber. Medical Lake samples were not equivalent to those collected by Ecology's composite samplers, but represented the STP's typical sampling procedures.

Ecology composite samples and Medical Lake grab samples were split for analysis by both Ecology and Medical Lake laboratories. Parameters analyzed, samples collected, and the sampling schedule appear in Appendix B.

Samples for Ecology analysis were put in appropriate containers and preserved as necessary. The samples were packed in ice and delivered to the Ecology Manchester Laboratory. Analytical procedures and laboratories performing the analyses are summarized in Appendix C.

Quality Assurance/Quality Control

Sampling quality assurance included priority pollutant cleaning of sampling equipment (Appendix D). One duplicate of a composite sample was analyzed to assess sample splitting and analytic consistency. Sampling in the field followed all protocols for holding times, preservation, and chain-of-custody set forth in the Manchester Lab Laboratory Users Manual (Ecology, 1991).

Laboratory QA/QC including holding times, spike and duplicate spike sample analyses, precision data, and control sample (LCS) analyses were typically within appropriate ranges. Initial and continuing calibration verification standards were within relevant USEPA (CLP) control limits. Procedural blanks were predominantly free from contamination. Qualifiers are included in the data table where appropriate. Specific QA/QC concerns are noted in Appendix D.

Results and Discussion

Flow Measurements

Effluent flows were measured by ultrasonic meter in conjunction with a 45° V-notch weir located at the end of the chlorine contact chamber. At the time of the inspection, the flow recorded by the effluent totalizer was generally used as the plant flow for NPDES permit reporting. The effluent weir was inspected by Ecology and it appeared to be properly configured. An instantaneous flow measurement by Ecology taken at the weir (0.091 MGD) compared closely with the Medical Lake metered instantaneous measurement (0.086 MGD). The daily flow rate calculated from totalizer values over a two-day period was 0.092 MGD.

Medical Lake estimated influent flow through pump records. Estimated average influent flow during the inspection was 0.25 MGD. Apparent average daily losses across the system for the month of September ranged from 0.1 MGD to 0.15 MGD and may be attributed in part to evaporation and infiltration. The lack of steady state flow makes verification difficult, but inaccurate flow measurements could produce a sizeable portion of the discrepancy between influent and effluent flows. Recalibration of pump flow measurements is recommended to produce greater accuracy and allow a better evaluation of plant loading. If necessary, a direct influent flow measurement device should be considered.

Wastewater General Chemistry

Influent

BOD₅ concentration in the influent (207 mg/L) fell within the typical medium concentration range for untreated domestic wastewater (*Table 1*). TOC influent concentration (104 mg/L) fell into the "weak" range and BOD₅ /TOC ratio was higher than typical (Metcalf & Eddy, 1991, pg. 83).

Influent total solids (600 mg/L) and total non-volatile solids (311 mg/L) (*Table 1*) fell into a "medium" concentration range for typical domestic influent (Metcalf & Eddy, 1991).

Effluent

Due to the long retention time in the facility (\approx 95 days), fairly uniform influent quality is assumed in order to estimate treatment. Inspection results showed a BOD₅ reduction from 207 mg/L in the influent to 44 mg/L in the effluent (79% removal) (*Tables 1&2*). BOD₅ removal efficiency compared well with other modified aeration designs (Metcalf & Eddy, 1991). Other oxygen demand parameters, TOC and COD, did not display comparable removal efficiencies.

Ecology composite samples showed a decrease in total suspended solids (TSS) from 144 mg/L to 98 mg/L with a removal efficient of approximately 33% across the plant ($Tables\ 1\&2$). Ammonia nitrogen (NH_3 -N) concentrations decreased from an average of 25.5 mg/L in the influent to 0.135 mg/L in the effluent ($Table\ 1$). Nitrification was accompanied by a greater than expected reduction in alkalinity. Nitrite-Nitrate nitrogen (NO_2+NO_3-N) concentrations increased, but was still less than 0.5 mg/L in the effluent ($Table\ 1$). Denitrification and/or incorporation of nitrogen into algae are likely explanations for the low NO_2+NO_3-N in the effluent. Total phosphorous removal efficiency exceeded 52%.

Treatment/Settling Lagoons

TSS and TOC removal occurred in the aerated lagoon. TSS increased across the two treatment/settling basins 6% and 16% respectively, and TOC increased 43% (Table 2). BOD₅ was not measured between lagoons. These increases and the relatively low removal efficiency across the STP most likely result from the growth of algae in the two settling basins. During the inspection the basins' waters were noticeably green. Calculated retention time for the two basins was about 95 days. Limiting the retention time in the basins may reduce algae growth, although this could also effect nutrient reduction.

Discharge Ditch

Little change was detected in TSS and TOC concentrations at the open channel 100 yards downstream of the effluent discharge ($Table\ 2$). Moderate increases in NH_3 -N and large increases in NO_2+NO_3 -N were seen at the same location. This may reflect a non-point discharge or the decomposition of algae and surrounding plant life in the channel.

NPDES Permit Comparisons

Table 3 compares inspection results to NPDES permit limits and compliance order limits. The compliance order acts as a guide for the Department of Ecology to exercise its prosecutorial discretion, but does not amend NPDES permit limits. This is intended to control discharges and still allow the present Medical Lake facility to continue operation until completion of the proposed facility upgrade.

Effluent BOD_5 and TSS concentrations and loads were all within compliance order monthly and weekly average limits (*Table 4*). Effluent loads for BOD_5 (32 lb/day & 28 lb/day) were all within NPDES permit limits (*Table 3*). The Ecology effluent TSS concentration and the Medical Lake effluent BOD_5 concentration failed to meet the NPDES monthly permit limit which restricts the effluent concentration to no more than 15% of the influent concentration if the influent concentration is less than 200 mg/L. The Ecology TSS effluent sample concentration was 67% and the Medical Lake BOD_5 effluent sample concentration was 20% of each respective influent concentration. The Medical Lake effluent sample produced a TSS load (78 lb/day) that exceeded the NPDES permit monthly average limit, but was within the weekly average limit. BOD_5 effluent concentrations were all greater than monthly NPDES permit limits, but within weekly average limits. TSS effluent concentrations were above both monthly and weekly NPDES permit limits. Effluent pH averaged 9.0 and exceeded the upper range of the permit limit by more than 6% (*Table 3*). The high pH is likely associated with the high algae population. It is suggested that Medical Lake determine the extent of this relationship.

An effluent flow rate of 0.09 MGD was well below the NPDES permit limit of 0.3 MGD (*Table 3*). The effluent fecal coliform count was well within compliance order and NPDES

permit limits. Ecology grab sample results were below detection and Medical Lake grab sample results were 20 and 40 colonies/100ml. Although chlorination achieved the desired fecal coliform levels, the total chlorine residual in the effluent composite sample was high (6.0 mg/L). A grab sample taken previous to the composite sample found total chlorine residual to be below detection (< 0.1 mg/L). Large variations in effluent chlorine residual concentrations appeared to have occurred. Chlorine concentration was also high in the open channel (0.6 mg/L). It is suggested that chlorine concentrations and contact time be modified to determine the lowest chlorine concentration which will achieve compliance with permit fecal coliform limits.

Split Samples

Sample Comparisons

Comparisons of the Ecology lab's results for all effluent samples and BOD_5 influent samples collected by Ecology and Medical Lake were good (*Table 4*). Medical Lake results were similar for the two effluent TSS samples and the two influent BOD_5 samples.

The Medical Lake laboratory effluent BOD₅ samples produced a relative percent difference of 39% between the Ecology and Medical Lake samples. Relative percent differences between the Medical Lake sample influent TSS and the Ecology sample influent TSS were 33% for Ecology lab results and 27% for the Medical Lake lab results. It is recommended that Medical Lake conduct influent composite or grab-composite sampling to improve representativeness.

Laboratory Comparisons

Agreement between Ecology and Medical Lake analytical results were mixed. Influent and effluent TSS results from both laboratories agreed closely (*Table 5*). Relative percent differences did not exceed 3% between influent pairs and 16% between effluent pairs.

BOD₅ composite influent and effluent comparisons were somewhat more divergent (*Table 4*). Medical Lake's influent results were generally higher, and effluent results generally lower than Ecology's results. Relative percent differences exceeded 50% between influent pairs and remained above 35% for any effluent pairs. It is reported that the lab performing the analyses does not dechlorinate BOD₅ samples before testing. Review of protocols for BOD₅ testing is advised.

The Medical Lake and the Ecology lab's fecal coliform results were similar, with the former reporting very low counts and the later reporting counts below detection (*Table 4*).

Testing for Medical Lake is currently performed by the city of Cheney Public Wastewater Treatment Plant Laboratory. This lab is not accredited. All testing laboratories need to be accredited by July 1, 1994 (173-220 WAC, 1992).

Wastewater Priority Pollutant Metals

Wastewater was analyzed for metals only. Arsenic, copper, selenium, and zinc were all detected in the effluent (*Table 5*). None exceeded either the EPA hardness adjusted water quality criteria for receiving waters (EPA, 1986) or the State of Washington Water Quality Standards for Surface Waters (173-201A WAC, 1992). Appendix E contains the results of all target metals.

Sludge

Characterization of lagoon sludge was done to determine its impact for potential land application. Kjeldahl-N concentrations for the sludge ranged from 10,100 - 22,000 mgN/Kg-dry wt. (Table 1). The composite total Kjeldahl-N concentration for all three basins was 20,700 mgN/Kg-dry wt. The calculated nitrogen limitation application rate based on nutrient uptake for selected field crops range from 1.8 to 7.3 tons dry solid/acre·year (Metcalf & Eddy, 1991). Assuming a sludge depth of one-third meter, a specific gravity of 1.01, and an average percent weight dry solids of 10%, the total weight of dry sludge from the three lagoons is approximately 1,654 tons. For a one time disposal to land under cultivation for wheat and alfalfa, this would require 227 and 918 acres of farmland, respectively.

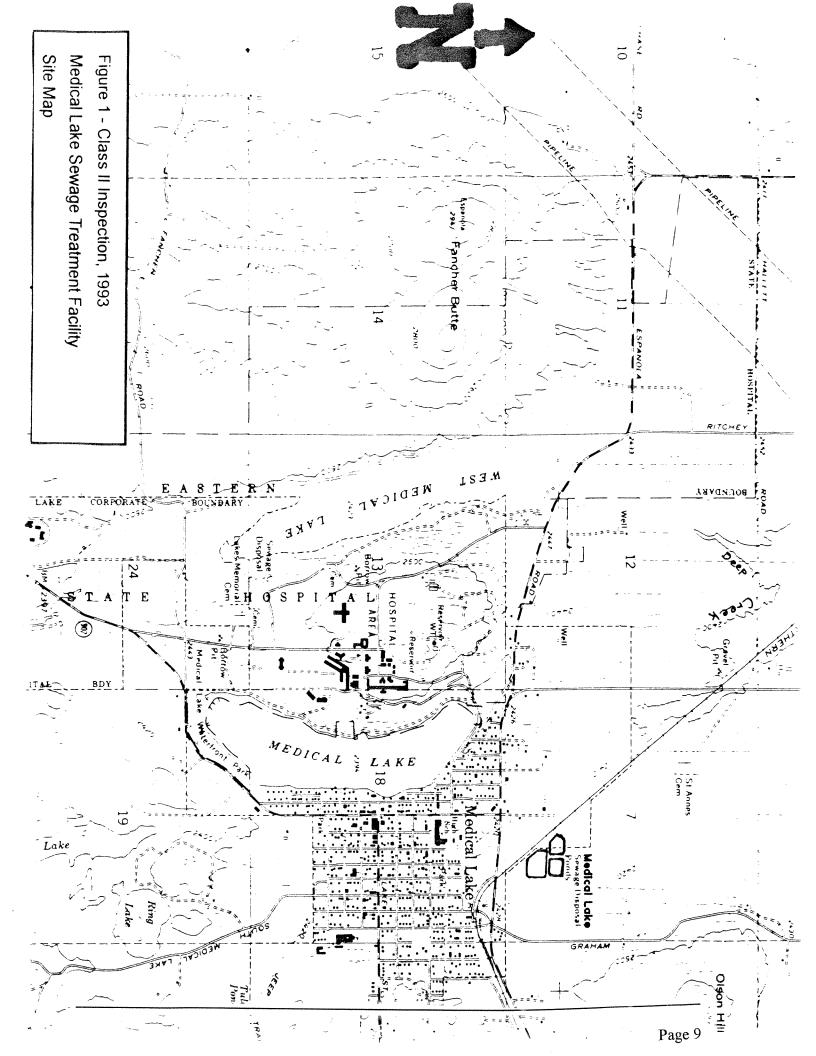

Fecal coliform densities ranged from 450/100g-wet wt. (64 colonies/g - dry wt.) in lagoon #3 to an average of 1,400,000/100g-wet wt. (100,000/g - dry wt.) in lagoon #1 (*Table 1*). The later density exceeds the Class A pathogen limitation for the land application of municipal sewage sludge of 1,000/g-dry wt. (EPA, 1993 - 40 CFR Part 503). The composite sample density of 220,000/100g-wet wt. (36,700/g - dry wt.) exceeds the limitation by a factor of 36.

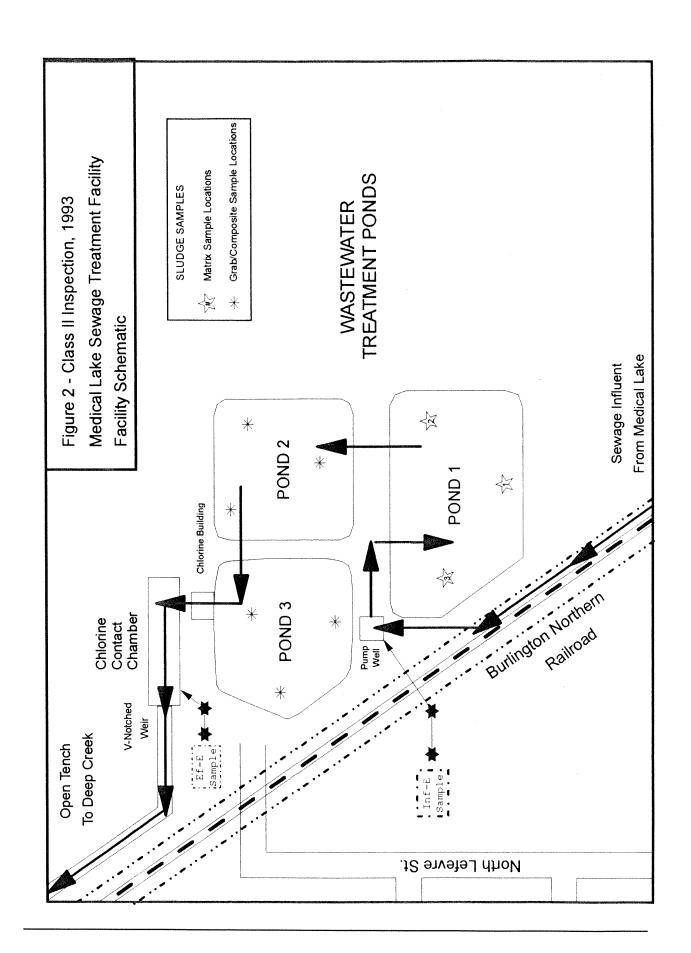

Sludge samples were analyzed for VOAs and BNAs as well as metals. Detected VOAs were all found in low concentrations (*Table 5*). Bis(2-Ethylhexyl)Phthalate was the BNA detected in the highest concentration (12,000 μ g/Kg-dry wt.). A complete list of target compounds and results is included in Appendix E. Tentatively identified compounds are presented in Appendix F.

Most priority pollutant metals were detected in all sludge samples (*Table 5*). None were detected in concentrations that exceeded the EPA metals criteria for the land application of municipal sludge (*Table 6*) (EPA, 1993).

Appendix A - Sampling Stations Description - Medical Lake, 1993

| Inf-E-1&2 | Grab sample of influent wastewater collected from the headwork diverter box - Collected in both A.M. and P.M |
|------------|--|
| Inf-E | Ecology 24-hour composite sample of influent wastewater collected from the headwork's wetwell. |
| Inf-M | Medical lake grab sample of influent wastewater collected from the headwork diverter box. |
| Ef-pond-1 | Grab sample of Lagoon #1 effluent taken from discharge pipe into lagoon# 2. |
| Ef-pond-2 | Grab sample of Lagoon #2 effluent taken from transfer box at discharge into lagoon #3. |
| Ef-E-1&2 | Grab sample of effluent from the weir overflow at the end of the chlorine contact chamber. |
| Ef-E-3&4 | Fecal coliform grab sample of effluent from the weir overflow at the end of the chlorine contact chamber. |
| Ef-E | Ecology 24-hour composite sample collected from the weir overflow at the end of the chlorine contact chamber. |
| Ef-M | Medical Lake effluent grab sample collected from the weir overflow at the end of the chlorine contact chamber. |
| Out-E | Grab sample taken from the open channel to Deep Creek approximately 150 ft downstream from the weir overflow at the end of the chlorine contact chamber. |
| Sludge-2 | Composite sample of bottom sludge collected from three locations in lagoon #2 |
| Sludge-3 | Composite sample of bottom sludge collected from three locations in lagoon #3 |
| Matrix-# | Individual bottom sludge samples collected in a matrix pattern from lagoon #1 |
| Sludge-123 | Composite sample of bottom sludge collected from the centers of all three lagoons. |
| Duplicate | Duplicate of effluent sample for blind analysis. |

Appendix D - Medical Lake Class II Inspection, 1993

Priority Pollutant Metal Cleaning Procedures for Wastewater Collection Equipment.

- 1. Wash with laboratory detergent
- 2. Rinse several times with tap water
- 3. Rinse with 10% HNO3 solution
- 4. Rinse three (3) times with distilled/deionized water
- 5. Allow to dry and seal with aluminum foil

Priority Pollutant Cleaning Procedures for Sludge Collection Equipment.

- 1. Wash with laboratory detergent
- 2. Rinse several times with tap water
- 3. Rinse with 10% HNO3 solution
- 4. Rinse three (3) times with distilled/deionized water
- 5. Rinse with high purity methylene chloride
- 6. Rinse with high purity acetone
- 7. Allow to dry and seal with aluminum foil

Specific QA/QC concerns

- 1. Water sample Procedural blanks detected the presence of arsenic and copper. The laboratory qualified these data with the "B" qualifier to indicate blank contamination when sample levels are less than ten times blank levels.
- 2. Sludge sample spike recoveries for antimony and thallium were outside of the CLP accepted limits. Antimony also exhibited a Relative Percent Difference (RPD) for precision and a Laboratory Control Sample (LCS) analysis outside the acceptable limits. Results for these elements are qualified with "N" or "J" depending on the severity of interferences found.
- 3. Semi-volatiles were extracted eight days past the SW-846 recommended holding times, but were analyzed within the 40 day extraction holding time. Detected results have been qualified with a "J" and non-detected analytes with a "UJ".
- 4. Semi-volatile analyses found matrix spike recovery for two compounds exceeded advisory QC limits. Results have already been qualified by "J" for holding time violations.
- 5. During the analyses of solids Manchester laboratory experienced a spill of phenol in their weighing room. This precluded the use of that room for weighing samples and weighing was done in a room without regulated humidity. This may have allowed some absorption of moisture during the weighing, slightly compromising the results. Consequently the lab has qualified all solids results with the "J" qualifier indicating that they are an estimate.

Appendix G - Tentatively Identified Compounds - Medical Lake, 1993

| Sample Location: | Sludge-123 |
|------------------|------------|
| Type: | grab/comp |
| Date: | 9/21/93 |
| Time: | 1520 |
| Sample ID: | 398148 |

Volatile Organics:

| Compound Name | Estimated Concentration | $(\mu g/\text{Kg-dry wt.})$ | Qualifier |
|----------------------------------|-------------------------|-----------------------------|-----------|
| 1. Unknown (b.p. m/e 207) | | 110 | J |
| 2. Silane Isomer (b.p. m/e 281) | | 150 | JN |
| 3. Unknown Hydrocarbon (b.p. 1 | m/e 57) | 260 | JN |
| 4. Unknown Hydrocarbon (b.p. 1 | m/e 57) | 440 | JN |
| 5. 7-Dimethyl-Undecane C13.H2 | 8 (b.p. m/e 57) | 480 | JN |
| 6. Unknown Hydrocarbon (b.p. | m/e 57) | 710 | JN |
| 7. 1-Methyl-4-(1-Methylethenyl)- | Cyclohexene C10.H16 | 290 | JN |
| 8. 8-Dimethyl-Undecane C13.H2 | 8 (b.p. m/e 57) | 130 | JN |
| 9. Unknown Hydrocarbon (b.p. | m/e 57) | 270 | JN |
| 10. Trimethyl-Dodecane (b.p. m/e | e 57) | 480 | JN |

Sample Location: Sludge-123
Type: grab/comp
Date: 9/21/93
Time: 1520
Sample ID: 398148

BNAs:

| Compound Name | Estimated Concentration (µg/Kg-dry wt.) | Qualifier |
|---|---|-----------|
| 1. 2,7,10-Trimethyl-Dodecane (b.p. m/e | 57) 34000 | JN |
| 2. Unknown Hydrocarbon (b.p. m/e 57) | 22000 | JN |
| 3. Unknown Hydrocarbon (b.p. m/e 69) | 20000 | JN |
| 4. Unknown (b.p. m/e 69) | 41000 | J |
| 5. Unknown (b.p. m/e 55) | 100000 | J |
| 6. Unknown (b.p. m/e 43) | 140000 | J |
| 7. Unknown (b.p. m/e 231) | 39000 | J |
| 8. Unknown (b.p. m/e 43) | 14000 | J |
| 9. Unknown (b.p. m/e 43) | 15000 | J |
| 10. Unknown (b.p. m/e 43) | 37000 | J |
| 11. Unknown (b.p. m/e 43) | 39000 | J |
| 12. Unknown (b.p. m/e 43) | 28000 | J |
| 13. 3,3-Thiobis-, Didodecyl Ester Propano | ic Acid 340000 | J |

J The analyte was positively identified. The associated numerical result is an estimate.

JN The analyte was tentatively identified. The associated numerical result is an estimate

Appendix H - GLOSSARY

ABN Acid base-neutral, semivolatile organics, see BNA

AED Atomic Emission Detector

BNA Base-neutral acids, semivolatiles, see ABN

BOD Biological Oxygen Demand CLP Contract Laboratory Program COD Chemical Oxygen Demand

co-elutants When two or more compounds have the same chromatographic retention time

CVAA Cold Vapor Atomic Absorption

d-deuterium An isotope of hydrogen

DL Detection Limit

DOC Dissolved Organic Carbon

DW Dangerous Waste

ECD Electron Capture Detector-Sensitive to halogen compounds - use: halogenated

hydrocarbons

EHW Extremely Hazardous Waste
ELD Electrolytic Detector - Hall
EP TOX Extraction Procedure Toxicity

Fatty Acid Monobasic organic acids derived from hydrocarbons; include both saturated

and unsaturated acids

FID Flame Ionization Detector-Sensitive to carbon compounds, used in the

determination of hydrocarbons

Flash Point Minimum temperature that will enable combustion or explosions to take place

FTIR Fourier Transform Infra-Red

GC Gas Chromatography

GCMS Gas Chromatography Mass Spectrometry, also GC/MS

HC Hydrocarbon

HDPE High Density Polyethylene HH Halogenated Hydrocarbon

HPLC High Performance Liquid Chromatography

HSD Halogen-Specific Detector - use: halogenated hydrocarbons

HW Hazardous Waste

HWPAH Hazardous Waste Polynuclear Aromatic Hydrocarbon

ICP Inductively Coupled Plasma

ICP/MS Inductively Coupled Plasma/Mass Spectrometry

IDL Instrument Detection Limit

isomer One of two or more substances which have the same elementary composition

but differ in structure and hence in properties

isotope One of two or more nuclides having the same atomic number, but differing in

mass number

Appendix H - (continued)

Isotopically The substitution of one or more isotopes for elements in a compound

labelled

kg kilogram (1 X 10³ grams) L Liter (1 X 10³ milliliters)

LC50 Concentration which is lethal to 50% of the test organisms

LOD Limit of Detection

LOEC Lowest Observable Effect Concentration

m³ Cubic meter (1 X 10³ liters)

MBAS Methylene Blue Active substances

metalloids Elements that exhibit transitional characteristics between metals and non-

metals, examples include silver, selenium, antimony

MF Membrane Filter

mg milligram (1 X 10⁻³ grams)
mL Milliliter (1 X 10⁻³ liters)
MPN Most Probable Number
ng Nanogram (1 X 10⁻⁹ grams)
nm Nanometer (1 X 10⁻⁹ meters)

NOEC No Observable Effect Concentration

NPDES National Pollution Discharge Elimination System

NPOC Non-Purgeable Organic Carbon NTU Nephelometric Turbidity Unit

OSHA Occupation Safety and Health Administration

OSW Office of Solid Waste PCB Polychlorinated Biphenyl

PE Polyethylene

pg Picogram (1 X 10⁻¹² grams) pH Hydrogen Ion Concentration

PID Photoionization Detector - use: aromatic hydrocarbons

PLM Polarized Light Microscopy POC Purgeable Organic Carbon

Polyvalent Capable of having more than one valance state

PP Priority Pollutant

ppb Parts per billion (1 X 10⁻⁹ ug/L or ug/kg) ppm Parts per million (1 X 10⁻⁶ ug/L or ug/kg) ppt Parts per thousand (1 X 10⁻³ ug/L or ug/kg)

PQL Practical Quantitation Limit

PUF Polyurethane Foam

SDWA State Drinking Water Act

SOW Statement of Work

SW Solid Waste

Appendix H - (continued)

TC Target Compounds or Total Carbon

TCD Thermal Conductivity Detector

TCL Target Compound List

TCLP Toxicity Characteristic Leaching Procedure

TDS Total Dissolved Solids

TIC Total Inorganic Carbon or for GCMS Tentatively Identified Compound

TNVS Total Non-Volatile Solids

TNVSS Total Non-Volatile Suspended Solids

TOC Total Organic Carbon
TP Total Phosphorous

TPH Total Petroleum Hydrocarbons

TS Total Solids

TSS Total Suspended Solids
TVS Total Volatile Solids

ug Microgram (1 X 10⁻⁶ grams)
ug/m³ Microgram per cubic meter
VOA Volatile Organic Analysis
VOC Volatile Organic Carbon
ZHE Zero Headspace Extractor
