

HYDROGEOLOGY AND GROUND-WATER
CONDITIONS IN THE CHUMSTICK
DRAINAGE BASIN

by

Linton Wildrick

OFTR 79-1

This Open File Technical Report presents the Results of a hydrologic investigation by the Water Resources Program, Department of Ecology. It is intended as a working document and has received internal review. This report may be circulated to other Agencies and the Public, but it is not a formal Ecology Publication.

Author: Linton Wildrick

Supervisor: Peder Grimstad

GROUND-WATER FLOW SYSTEM OF THE CHUMSTICK DRAINAGE BASIN

On behalf of the Department of Ecology, I have conducted a preliminary investigation of the ground-water flow system along Chumstick Creek and its tributaries. During 11 days of field investigation in October and November of 1978 and January of 1979, I visited numerous wells and springs. I was assisted during the first 5 days by Mr. Ken Slattery, and during the next 5 days by Ms. Vicki Colgan. At each site we made a water level measurement (depth to water) and an altitude measurement (height above sea level). When possible, we discussed the wells or springs with property owners to supplement information available from drillers' logs (reports giving details of well construction and of the geologic strata encountered). Natural outcrops, road cuts, and stream banks were examined to obtain geologic information on the water-bearing properties of sediments filling the valleys as well as the sedimentary bedrock beneath. In addition, I spent one day in December of 1978 conferring with Dr. John Whetten of the University of Washington and the U.S. Geological Survey. Dr. Whetten furnished me a preliminary (unpublished) bedrock geology map for the Chumstick area.

I present herein my findings and interpretations. Because of the limited scope of this investigation, our understanding of the Chumstick Creek hydrologic system is too elementary and generalized to provide detailed knowledge of individual parcels of private land. Furthermore, we didn't visit every well and spring in the drainage basin. We chose only those easily accessible and sufficiently spaced throughout the basin to get basic information on water levels and geology.

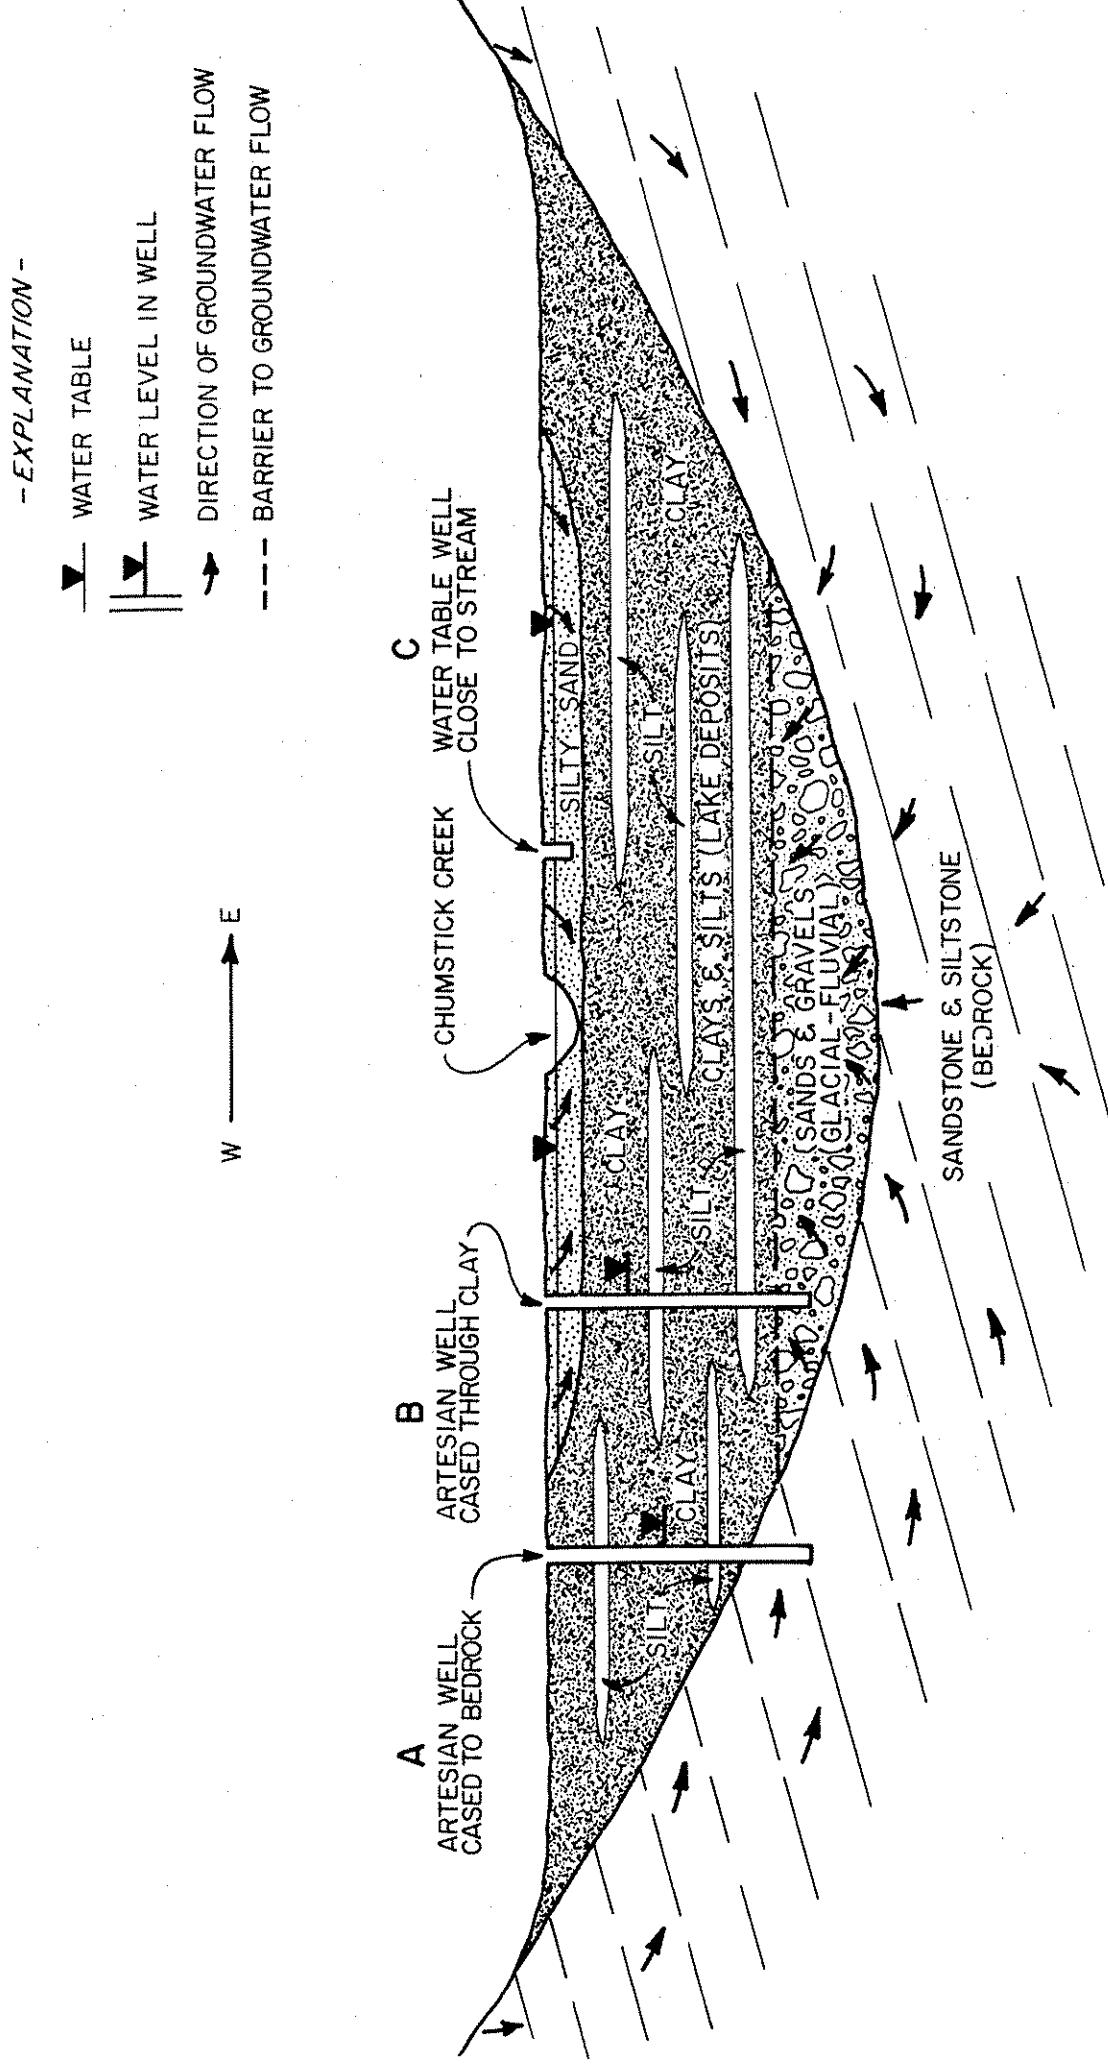

GEOLOGY OF THE DRAINAGE BASIN

The geologic logs from driller's reports, together with outcrop mapping during our field investigations, were used to compile the generalized geologic cross-section illustrated in Figure 1.

Bedrock

Sedimentary bedrock composed largely of sandstone and siltstone has been folded by tectonic forces and cut by streams to form the basic shape of the Chumstick and its tributary valleys. On the steep valley walls the bedrock is exposed in cliffs or thinly veneered with soil anchored by vegetation. The sand and silt grains of the rock are weakly cemented by clay and carbonate, leaving many tiny interstitial pores open to the movement of water. There are many cracks and bedding plane discontinuities (where, say, a sandstone layer adjoins a siltstone layer) along which water may move. The sandstones are able to absorb much of the rain and snow melt that falls on the thin soils and exposed rock of the ridges and valley walls. The bedrock can thus be a useful aquifer.

Figure I. GENERALIZED CROSS-SECTION OF CHUMSTICK VALLEY ILLUSTRATING GROUND-WATER FLOW SYSTEM.

Valley-Fill Deposits

The bedrock floors of the valleys are covered by sediments ranging in thickness from 5 feet or less on the valley margins to 150 feet or more toward the center of the valleys. Under the flat flood-plains of the valley floors where the sediments are thickest, one can characterize up to three successive sets of strata: (1) an uppermost thin deposit (5 to 10 feet thick) of silty sand; (2) beneath the silty sand layer is a series of clay and silt beds (fine-grained) with minor amounts of sand and gravel which, in turn, overlie beds composed entirely of (3) sand and gravel (coarse-grained). This complete sequence of beds is found only in the lower half of the drainage (south of T 26 N) along Chumstick Creek, Eagle Creek, and Spromberg Canyon. In the northern half of the drainage basin, the lowermost sand and gravel strata is missing. The same is true toward the margins of the valleys where the valley-fill deposits are thinner and only the clay and silt beds are found above the bedrock. The origins of these three units are explained in the following text, beginning with the lowermost and therefore oldest set of strata.

The sand and gravel beds of the lowermost valley-fill may have been deposited by glacial meltwater streams significantly larger and swifter than the present creeks, perhaps as large at the present-day Wenatchee River. These deposits are coarse-grained and have large, intergranular pores through which water may easily flow and which provide for a large volume of water storage.

The silts and clays, which overlie the sands and gravels, are probably lake deposits laid down during intervals when the glacial meltwater streams were dammed by ice. A glacier emerged from Tumwater Canyon, covered the Leavenworth Valley, and thereby blocked the mouth of the Chumstick Valley. Wells cased through the clays to the underlying sand and gravels, invariably have artesian "heads"; that is, the water entering the well rises to a level above the top of the aquifer. The relatively impervious silt and clay apparently traps the water in the underlying aquifer, causing hydrostatic pressure buildup.

The uppermost silty-sand unit corresponds to the present-day bedload of Chumstick Creek and its tributaries, suggesting deposition during the time since the last glacial epoch (approximately 12,000 years ago). The silty sands are derived from erosion of the sandstones and shales on the surrounding ridges. Water is obtained from shallow wells in these uppermost sediments, especially close to the creek. This "water table" aquifer supplies water to the creeks throughout the year. There may be more silty-sand strata below, but geologic logs from drillers don't adequately differentiate the various strata.

AQUIFER CHARACTERISTICS

There are essentially three types of aquifers (water-producing zones or beds) being utilized in the Chumstick drainage basin: (1) the shallow water-table aquifer composed of the uppermost silty sand; (2) the lowermost sandy and gravelly sediments lying just above bedrock in the

thicker sections of valley-fill (this is an artesian aquifer); and, (3) the sandstone bedrock, also an artesian aquifer. These aquifers and the wells constructed to utilize them are explained in the following text.

High-rate pumping of shallow wells in the water-table aquifer placed close to the creek (say, within 100 feet) may cause creek water to infiltrate the creek bed and flow toward the well. A cone-shaped depression forms in the water table around the well and spreads outward for a distance dependent on the pumping rate and the hydraulic properties of the sediments. Ground-water flows down the slope or "hydraulic gradient" of this "cone-of-depression". Creek water moves toward the well if the cone reaches near enough to the creek to reverse the "hydraulic gradient" which normally slopes toward the creek. These shallow wells are dug by hand or backhoe rather than by drilling methods and are cased with concrete tile.

Wells drilled to the sand and gravel aquifer of the lowermost valley-fill are cased through the beds of silty sands and the intervening clay and silt beds. The casing extends into the aquifer and water enters the well through the open end of the casing or through perforations in the casing. The pressure in this artesian aquifer causes the water to rise in the well as much as 50 feet above the top of the aquifer, and wells have produced as much as 6 gpm per foot of drawdown.

Wells drilled along the valley margins penetrate the clay and silt valley-fill to water-bearing beds of the sandstone (bedrock) aquifer. This artesian aquifer has water pressures equivalent to those of the sand and gravel aquifer; that is, up to 50 feet or more of water above the top of the aquifer. The bedrock has been found to produce up to 2 gpm per foot of drawdown.

Table 1

Record of Wells, Chumstick Creek Drainage Basin

Explanation:

Well Number:

Wells are designated by symbols that indicate their location according to the rectangular-grid system for subdivision of public land. For example, in the symbol 20/2-11R1 the part before the hyphen indicates successively the township and range (T. 20 N., R. 2 E.) north and east of the base line and Willamette meridian. The first number after the hyphen indicates the section (11) in which the well is located; the letter denotes the 40-acre subdivision of the section according to the following diagram. The last number is the serial number of the well in the 40-acre subdivision. For example, well 20/2-11R1 is in the SE1/4SE1/4 sec. 11, T. 20 N., R. 2 E., and is the first well in that tract to be listed.

D	C	B	A
E	F	G	H
M	L	K	J
N	P	Q	R

Owner or Tenant:

Also include owner's well number, if known.

Altitude:

Altitude of land surface in feet obtained by altimeter survey (A) or interpolated from topographic maps (M). Altimeter readings are accurate to ± 10 feet while map interpolations are accurate to ± 20 feet.

Type of Well:

Dr, Drilled; Dg, Dug.

Openings:

Perf, perforated; Scr, screened; OE, open-end when casing is present but not screened or perforated. Numbers indicate depth intervals of the screened or perforated casing.

Aquifer Character:

C, confined; UC, unconfined.

Table 1 continued

Depth to Water Below Land Surface:

Water-level measurements expressed in feet and decimal fractions of feet were made by the Department of Ecology, Water Resources Investigations Section. Measurements recorded to the nearest whole foot were reported by owner, tenant, or driller; the dates of such measurements are often not known. A flowing well whose static head is known has "+" preceding the water level, indicating static head in feet above land-surface datum. A flowing well whose static head is not known is indicated by "Flows".

Hydraulic Interference with Creek:

Occurs when well is sufficiently close to creek that pumping water from the well would cause creek water to infiltrate the stream bed and move underground toward the well.

Remarks:

D.D. = drawdown; GPM = gallons per minute; Spec. Cap. = Specific capacity, gallons per minute per foot of drawdown.
